COMPLETE FARMER:

OR, A GENERAL

DICTIONARY OF HUSBANDRY

IN ALL ITS BRANCHES;

CONTAINING THE VARIOUS

Methods of Cultivating and Improving every Species of Land,

ACCORDING TO THE PRECEPTS OF BOTH THE

OLD AND NEW HUSBANDRY.

Comprising every Thing valuable in the best Writers on this Subject, viz. LINNÆUS, CHATEAUVIEUX, the Marquis of TURBILLY, PLATT, EVELYN, WORLIDGE, MORTIMER, TULL, ELLIS, MILLER, HALE, LISLE, ROQUE, MILLS, YOUNG, MARSHALL, &c. &c.

TOGETHER WITH

A great VARIETY of NEW DISCOVERIES and IMPROVEMENTS.

ALSO

The whole Business of Breeding, Managing, and Fattening CATTLE and POULTRY of all Kinds; and the most approved Manner of curing the various Diseases to which they are subject. Together with the Manner of raising BEES, and of acquiring large Quantities of WAX and HONEY, without destroying those laborious INSECTS. Also, the Management of VINES, and the best Method of making all Sorts of WINES.

Illustrated with a great Variety of COPPER-PLATES, accurately engraved; exhibiting all the Instruments used in HUSBANDRY; particularly those lately invented, as well as those presented to the Society for the Encouragement of Arts, &c. in London; many of which have never yet appeared in a Work of this Nature.

The FOURTH EDITION, considerably IMPROVED, and greatly ENLARGED.

By A SOCIETY of GENTLEMEN,

MEMBERS OF THE SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.

L O N D O N,

PRINTED FOR T. LONGMAN, B. LAW, G. G. J. AND J. ROBINSON, T. CADELL, R. BALDWIN, W. OTTRIDGE,
AND W. LOWNDES.

ADVERTISEMENT.

HUSBANDRY is, with great justice, placed at the head of human arts, as having a very great advantage over all others, both with regard to antiquity and usefulness. It had its birth with the world, and has always been the genuine source of solid wealth, and real treasures; for it will furnish a people with every thing necessary to render life happy and desirable, form the principal revenues of the state, and even supply the defect of all others, when they happen.

It is therefore no wonder that the wisest princes, and the most able ministers, among the ancients, made it their principal study to encourage and improve the Art of Husbandry; they well knew that the strength of a state should not be estimated by the extent of its territories, but by the number of its inhabitants, and the utility of their labours. And it should be remembered, that some of the most noble consuls and dictators among the ancient Romans were taken from the Plough, and that the senators of that flourishing people spent the greater part of their time in the country, where they tilled their fields with their own hands. “In those happy times, says Pliny, the earth, pleased at seeing herself cultivated by the hands of triumphant victors, seemed to make stronger efforts, and to produce her fruit in greater abundance.” Doubtless because they applied themselves to the task with greater attention, and took the wisest precautions to render their labours successful: for when men of genius and abilities apply themselves to any art, they soon make great improvements, and advance it to a much higher degree of perfection: while the common people, by servilely confining themselves to the common mode of practice, seldom make any farther progress in their profession.

But when destructive luxury was introduced among the old Romans, Husbandry declined, and has never since reached the honourable station it before possessed: owing in a great measure, to an opinion founded on falsehood, namely, that the practice of Husbandry requires neither study, reflection, nor precepts; and is therefore beneath the notice of men of fortune and genius. The ancients, however, thought very differently: they were persuaded, that, in order to cultivate lands to advantage, it was necessary to study the works of those who had written on this subject, and to add the experience of others to their own. This opinion is now happily established; and the Study of Husbandry pursued with such assiduity in different parts of Europe, by persons of rank and fortune, that an amazing number of the most important discoveries have been lately made in that useful and necessary branch of knowledge.

But these useful Discoveries and Improvements are scattered through a multitude of volumes, written in different languages, and published in different countries; so that they can only be known to those who have abilities to purchase, and leisure sufficient to peruse so great a variety of books.

A D V E R T I S E M E N T.

The authors of this undertaking were therefore persuaded, that a Work, containing the Precepts relating to the Theory and Practice of every Branch of Husbandry, delivered in the plainest and most intelligent manner, and enriched with the Discoveries hitherto made in any part of Europe, would greatly tend to promote the Interest of their country. Filled with this pleasing Idea, they cheerfully undertook the laborious task; and have accordingly collected in this Dictionary all the valuable Precepts, Observations, Discoveries, and Improvements, contained in the writings of *Linnaeus, Barck, Tarello, Dubamel, Chateauvieux, De Lisle*, the Marquis of *Turbilly, Fitz-Herbert, Hartlib, Platt, Evelyn, Houghton, Worlidge, Stillingfleet, Mortimer, Tull, Ellis, Miller, Hale, Lisle, Roque, Mills, Young, Marshall*, and several other Authors; together with those published by the Societies of *Berne, Lyons, Tours, Paris, Rouen, Dublin, Edinburgh, London, &c. &c.*

And they hope that this Attempt to give a COMPLETE SYSTEM of every branch of Husbandry, and to blend in One Work the various Discoveries made in different Nations, deserves the most serious Encouragement. They also hope that the pains they have taken to insert every thing belonging to the same subject in one article, and to range the whole in alphabetical order, will be approved of by the Public, as it evidently tends to facilitate the Study of Husbandry, by enabling the Reader to find, with the greatest ease and expedition, whatever subject he may be desirous of considering.

The great number of COPPER-PLATES with which this work is illustrated, must also prove a very valuable addition, and render it far superior to any single Treatise of this kind ever yet offered to the world; as it is impossible to convey an adequate idea of the various instruments, lately invented or improved, for facilitating the practice of Husbandry, without the assistance of accurate drawings. This has, however, rendered the work far more expensive: but being determined to make it as complete as possible, they have spared nothing in their power to succeed; as the great success works of this kind have met with from the generous Public, and of which they hope to partake, in proportion to the merit of the production.

GENERAL DICTIONARY

OF

HUSBANDRY.

A B E

A B O

ABELE-TREE, a species of poplar, growing naturally in all the temperate parts of Europe, and called by botanists *populus foliis lobatis dentatis subus tomentosis*.

The leaves of the abele-tree are large, and divided into three, four, or five lobes, which are indented on their edges, of a very dark colour on their upper side, but very white and downy on their under, standing upon foot-stalks about an inch long. The young branches have a purple bark; and are covered with a white down; but the bark of the stem and older branch is grey. In the beginning of April, the male flowers or catkins appear, which are cylindrical, scaly, and about three inches long; about a week after come out the female flowers, or catkins, which have no stamina like those of the male. Soon after these come out, the male catkins fall off, and in five or six weeks after, the female flowers will have ripe seeds inclosed in a hairy covering; then the catkins will drop, and the seeds will be wafted by the winds a great distance. This tree is often confounded with the white poplar; but they are in reality distinct species.

The abele-tree may be propagated either by layers or cuttings, which will readily take root, or by suckers, which they send up from their roots in great plenty. The best time for transplanting these suckers is in October, when their leaves begin to decay. These may be placed in a nursery for two or three years to get strength before they are planted out where they are designed to remain; but if they are propagated from cuttings, it is better to defer the work till February, at which time truncheons of two or three feet long should be thrust about a foot and a half into the ground. These will readily take root, and, if the soil, in which they are planted, be moist, will arrive to a considerable bulk in a few years.

A considerable advantage may be made by planting these trees upon boggy soils, where few other trees will thrive. Many such places there are in England, which do not at present bring in much money to their owners; whereas, if they were planted with these trees, they would in a very few years, be of more value than the ground, clear of all expences; but there are many persons, who think nothing, except corn, worth cultivating in England; or, if they plant timber, it must be oak, ash, or elm; and if their land be not proper for either of these, it is considered as of little value: whereas, if the nature of the soil was examined, and proper sorts of plants adapted to it, there might be very great advantages made of several large tracts of land, which at this time lie neglected.

The wood of the abele-tree is very good for floors, where it will last many years, and for its exceeding whiteness is, by many persons, preferred to oak; but being of a soft nature, is very subject to take the impressions of nails, &c. which renders it less proper for this purpose. It is also very good for wainscoting rooms, being less subject to swell or shrink

than most other woods; but for turnery-ware there is no wood equal to this for its exceeding whiteness. So that trays, bowls, and many other utensils are made of it; the bellows-makers also prefer it for their use, as do also the shoe-makers for heels of shoes; it is likewise very good to make light carts, and the poles are very proper to support hops, vines, &c. and the lopping will afford good fuel, which in many countries is much wanted. *Miller's Dict.*

The abele-tree is very proper for planting where you desire a speedy shelter and walks, it often making shoots of eighteen or twenty feet long in a year. *Mortimer's Husbandry.*

ABLAQUEATION, the removing the earth, and laying bare the roots of fruit trees in winter, that they may be the more readily exposed to the influence of rains, snow, air, &c. an operation formerly thought necessary for their future welfare; but experience has shewn it to be a dangerous practice, especially where the trees are much exposed to the winds, particularly the south-west, which are generally the most violent. The practice of ablaqueation is therefore with very good reason laid aside in the present practice.

ABORTIVE CORN, a distemper of corn mentioned by Mr. Tillet, in a Dissertation which gained the prize at the academy of Bourdeaux.

This distemper, says that ingenious naturalist, shews itself long before harvest, when the stalk is not above eighteen inches high; and may be known by a deformity of the stalk, the leaves, the ear, and even the grain.

The stem of abortive corn is generally shorter than that of other plants of the same age; it is crooked, knotted, and ricketty; the leaves are commonly of a bluish green colour, curled up in various forms; sometimes turned like wafer cakes, and often rolled in a spiral form. The ears have very little of their natural form; they are lean, withered, and shew very imperfect rudiments, either of the chaff or grain.

All these symptoms are however only to be found in plants that are in the height of the distemper. The stalks are often pretty strait, the leaves but little curled, and the chaff tolerably well formed; but instead of enclosing a small embryo, white and soft at the summit, it contains only a green kernel terminating in a point, not unlike a young pea when forming in its pod.

These abortive kernels have two or three points very visible; they are then fashioned as if two or three kernels were joined together at the base. When these kernels are ripe, or rather when they are dried up, they grow black, and so greatly resemble the seeds of cockle, that husbandmen, who are not acquainted with this distemper, often confound abortive wheat with the seeds of that weed.

This distemper, Mr. Tillet suspects to be occasioned by insects; for he perceived on the sickly plants small drops of a very limpid liquor, which he judged to be extravasated sap.

ACORNS, the fruit of the oak, and too well known to need any description. See **OAK**.

Acorns are said to have been the primitive food of mankind; but at present they are principally used in fattening hogs, for which they are very proper.

Mr. Marshall, in his *Rural Economy of Gloucestershire*, says, that acorns in the vale of Berkeley are in high esteem. The farmers there seem to be as anxious about their acorns as their apples. They consider them as the best of fattening. They think the acorns make the bacon firm, and cause it to weigh better than bean-fed bacon. How various are opinions in different countries! The price of acorns there is 1s. and 6d. to 2s. per bushel, according to the season; and according to the price of beans. But few are sold. Every farmer collects his own, or tends his pigs upon them. Acorns in the year 1783 were unusually plenty, when several trees had branches broken down with them; and many bent down like apple or pear trees under their load.

Some care is, however, necessary to be taken when hogs are fed upon acorns, for otherwise they will be subject to a distemper called the garget. To prevent which, the best way is to moisten some pease or beans with water, and sprinkle over it some antimony pounded and sifted; if this be repeated every other day for a fortnight or three weeks, it will effectually preserve them from the disorder. Or if the acorns be collected and prepared in the following manner, they may be given to hogs without any danger.

Dig a hole in the ground in a warm place, large enough to contain several bushels of acorns; in this let the acorns be put, and well moistened with water, in which a handful or two of common salt has been dissolved: in a few days they will begin to heat and spire: observe them therefore attentively, and when they have made a shoot about three inches long, take them out of the hole, and spread them to dry on a barn floor, and in a day or two they will be fit to be given to the hogs. This matter must, however, be managed with care and caution; they must not have too many given at a time; at first twice a day is often enough to feed them for a day or two; afterwards three times a day. Nor should they, while they eat this food, be confined to a sty, but suffered to run at large; for if their liberty be too much abridged, they will never thrive well, or grow fat on acorns.

It is no uncommon thing in Hertfordshire, with the management above directed, and the assistance of a little wash, and a few grains now and then, for a farmer to kill several hogs in a season, which shall weigh from eight to ten score, and sometimes even more.

These hogs make very good meat, but it is not so fine as when the hogs are taken up, and four or five bushels of pease or barley meal given to each, to complete their fattening before they are killed. *Museum Rusticum*, Vol. I. p. 475.

The method of planting acorns by some is to raise plants by making a hole to receive the acorn in an oblique direction, so as to raise up a tongue of turf, under which the acorn is to be deposited, where it will require no kind of nursing. In about thirty years the spat will be fit to be coppiced, that is, partially cut down as underwood, leaving the most healthy plants. The weeding may be sold for railing, and will fetch a good price. Mr. Marshall says that a piece of ground somewhat more than four acres, in Warwickshire, planted about 1730, has already paid its owner upwards of 400%. and the timber, is still too thick; some of them are worth twenty to twenty-five shillings a tree, from 40 to 50 feet high, and from 6 to 10 inches timber girth. The soil is an hungry clay, worth about 7s. or 8s. an acre; the clay continuing a considerable depth.

Acorns might be dibbled in by women. Indeed they are frequently scattered over some grounds, two or three within a square yard, by some unaccountable manner if not by rooks or wood-pigeons, and trodden into the ground by cattle. They may be sown broad cast, when the surface is moist, and rolled in with a light roller. On examination, after the plants appear, the acorns remain as perfect as they could be the day they were dropt, notwithstanding some of the seedling plants may be six inches high, and their roots not less than a foot long. From the manner in which the acorns adhere to the plant, which is by two tough ligaments growing out of the two lobes of the acorn, the roots appear to have struck first, and the stem to have afterwards shot up from it. They may be sown about the middle of November, set out by a land chain, a quarter of

a rod asunder, and six inches apart in the rows; dibbling them in zigzag, alternately on either side, a line stretched tightly on the surface, with blunt-pointed dibbles, letting a little mould fall down to the bottoms of the holes, to prevent water lodging round the acorns, burying them about two inches beneath the surface. Each square rod planted this way takes 132 acorns, nearly the contents of a pint when they are middle sized. A pint a rod is equal to two statute bushels and half on an acre. The expence of planting acorns in this way is about 5s. an acre.

ACRE, a superficial measure of land, containing, according to the statute, one hundred and sixty square poles or perches, of sixteen feet and a half long.

But this measure does not prevail in all parts of England; for though one hundred and sixty square poles or perches, are allowed to be an acre, yet the length of the pole varies in different counties, and is generally called customary measure.

Thus the customary perch in Staffordshire is twenty-four feet. In the forest of Sherwood twenty-one. In Herefordshire the perch of walling is sixteen feet and a half; but a perch for digging twenty-one feet.

Old farmers also estimate the acre of land by the proportion of seed used in sowing it; by which means it must vary in proportion to the fertility or barrenness of the soil; and hence in many counties of England they have two sorts of acres, distinguished by seed acres and statute acres.

The French acre, or arpent, according to Mr. Greaves's calculation, consists of 100 perches of twenty-two feet each, amounting to 48,400 square French feet, which are equal to 51,691 square English feet, or very near one acre, and three quarters of a rood, English measure.

The Irish acre is to the English, as 196 to 121. For the number of poles in each are the same; but the Irish pole is twenty-one feet, whereas the English contains only sixteen feet and a half: and the Welch acre is equal to two English statute-acres.

ACREME, a quantity of land consisting of ten acres.

ADDER'S-TONGUE, a weed growing in low moist meadows, where it is commonly hid among the grass.

From a very low stalk arises a single, thick, smooth oblong leaf, from the bottom of which issues a kind of tongue, ending in a point, and indented on each side like a file.

ADDER-STUNG, is said of cattle when stung by adders, or bit by a hedge-hog; to remedy which use an ointment made of dragon's blood with a little barley meal and the white of an egg.

AFTERMATH, the second crop, or grass which springs up after mowing, or the grass cut after the corn.

In the neighbourhood of London, the aftermath when made into hay, is of considerable value: but in haying this crop, so as to make it sell well, great nicety is requisite; the nature of the aftermath-grass being more soft, spongy, and porous, than the first growth, and therefore more liable to be hurt by rains. See **HAY**.

Mr. Marshall, in his *Rural Economy of the Midland Counties*, commends their management of aftergrass, as in general judicious. It is generally suffered to get up to a full bite before it be broken: not turned in upon, as soon as the hay is off, nor suffered to stand until much of it be wasted.

If we examine the remaining herbage of ground recently mown, we find it consist, either of the stubs and root-leaves of plants which have run up to seed, or of weak underling plants which have not been able to cope with their more powerful neighbours, or of late flowering plants.

The quality of the first is, of course, injured by age, and by the strength of the root having been spent on the upper leaves, fructifications, and seeds. That of the second cannot be good: they are in a similar predicament to grass growing under a hedge, or in a wood, checked in their growth, and shaded from the sun. And the last partakes, in some degree, of the same disadvantages; though, of the three classes, they probably contain the most nourishment.

Two of the ablest rural economists of these kingdoms, (one in Lancashire, the other in Leicestershire) make a point of saving autumnal grass for spring-feed; and they assert that it is the most certain, and on the whole the best spring-feed at present known. The forwardest ought to be broken sufficiently early to be eaten, without waste, before winter set in; and the latest, that is to say, the shortest, should be shut up for spring-feed. If aftergrass be too long and grossly it is apt to lodge, and rot upon the ground in winter; therefore on rich land it ought to be more or less

less fed before Michaelmas ; and then, of a due length, be shut up for the winter.

Mr. Young, in his *Annals of Agriculture*, says, that he found, from repeated experiments, that this old grass feeds the sheep, that give milk, better than turnips, which are more adapted to dry or fatten stock. He further says, that this grass holds to a period, if wanted when most other resources fail, the last half of April, and the first half of May ; periods always of want and difficulty, where rye grass is not sown. Mr. Marshall says, that as a certain and wholesome supply of food for ewes and lambs in early spring, this preserved pasture is depended upon as the sheet-anchor ; in preference to turnips, cabbages, or any other species whatever of what is termed spring-feed.

AGE of a horse. This is easily known by his mouth, till he comes eight, after which the usual marks wear out. A horse, like many other brute animals, has his teeth divided into three ranks, viz. his fore-teeth, which are flat and smooth, his tusks, and his back-teeth. His back-teeth, or jaw-teeth, are called his grinders, being those by which a horse chews and grinds his provender, and are twenty-four in number, twelve above, and twelve below : they are strong double teeth with sharp edges ; but when a horse grows old they wear much smoother.

The first that grows are his foal teeth, which begin to appear a few months after he is foaled : they are twelve in number, six above, and six below ; and are easily distinguished from the teeth that come afterwards, by their smallness and whiteness, not unlike the foreteeth of a man.

When the colt is about two years and a half old, he casts the four middlemost of his foal-teeth, viz. two above and two below ; but some do not cast any of their foal teeth, till they are near three years old. The new teeth are easily distinguished from the foal teeth, being much stronger, and always twice their size, and are called the nippers or gatherers, being those by which a horse nips off the grass, when he is feeding abroad in the fields, or, in the house, gathers his hay from the rack. When a horse has got these four teeth complete, he is reckoned three years old.

When he is about three and a half, or in the spring before he is four years old, he casts out four more of his foal teeth, viz. two above, and two below, one on each side the nippers, or middle teeth : so that when you look into a horse's mouth, and see the two middle teeth full grown, and none of the foal teeth, except the common teeth remaining, you may conclude he is four that year, about April or May. Some indeed are later colts, but that makes little alteration in the mouth.

The tusks appear near the same time with the four last mentioned teeth, sometimes sooner than these, and sometimes not till after a horse is full four years old : they are curved like the tusks of other beasts, only in a young horse they have a sharp edge all round the top, and on both sides, the inside being somewhat grooved and flattish, inclined to a hollowness.

When a horse's tusks do not appear for some time after the foal teeth are cast out, and the new ones come in their room, it is generally owing to their foal teeth having been pulled out before their time, by the breeders or other dealers in horses, to make a colt of three years old appear like one of four, that he may be the more saleable ; for when any of the foal teeth have been pulled out, the others soon come in their places ; but the tusks having none that go before them can never make their appearance till their proper time, viz. when a horse is about four, or coming four ; and therefore one of the surest marks to know a four year old horse, is by his tusks, which are then very small, and sharp on the top and edges.

When a horse comes five, or rather in the spring before he is five, the corner teeth begin to appear, and at first but just equal with the gums, being filled with flesh in the middle. The tusks are also by this time grown to a more distinct size, though not very large : they likewise continue rough and sharp on the top and edges. But the corner teeth are now most to be remarked ; they differ from the middle teeth in being more fleshy on the inside, and the gums generally look rawish upon their first shooting out, whereas the others do not appear discoloured. The middle teeth arrive at their full growth in less than three weeks, but the corner teeth grow leisurely, and are seldom much above the gums till a horse is full five : they differ also from the other fore-teeth in this, that they somewhat resemble a shell ; and thence are called the shell teeth, because they environ the flesh in the middle half way round ; and as they grow,

the flesh within disappears, leaving a distinct hollowiness and openness on the inside. When a horse is full five, these teeth are generally about the thickness of a crown piece above the gums. From five to five and a half they will grow about a quarter of an inch high, or more ; and when a horse is full six, they will be near half an inch, and in some large horses a full half inch above the gums.

The corner teeth in the upper jaw fall out before those in the under, so that the upper corner teeth are seen before those below ; on the contrary the tusks in the under gums come out before those in the upper.

When a horse is full six years old, the hollowiness on the inside begins visibly to fill up and that which was at first fleshy grows into a brownish spot, not unlike the eye of a dried garden bean, and continues so till he is seven ; with this difference only, that the tooth is more filled up, and the mark, or spot, becomes faint, and of a lighter colour. At eight the mark in most horses is quite worn out, though some retain the vestiges of it a long time ; and those who have not had a good deal of experience, may sometimes be deceived by taking a horse of nine or ten years old for one of eight. It is at this time only, when a horse is past mark, that one can easily err in knowing the age of a horse ; for what practices are used to make a very young horse or colt appear older than he is, by pulling out the foal teeth before their time may be discovered by feeling along the edges where the tusks grow, for they may be felt in the gums before the corner teeth are put forth ; whereas, if the corner teeth come in some months before the tusks rise in the gums, we may reasonably suspect that the foal teeth have been pulled out at three years old.

It will perhaps, be needless to mention the tricks that are used to make a false mark in a horse's mouth, by hollowing the tooth with a graver, and burning a mark with a small hot iron ; because those who are acquainted with the true marks, will easily discover the cheat by the size and colour of the teeth, by the roundness and bluntness of the tusks, by the colour of the false mark, which is generally blacker, and more impressed than the true mark, and by many other visible tokens, which denote the advanced age of a horse.

After the horse has passed his eighth year, and sometimes at seven, nothing certain can be known by the mouth. It must, however, be remembered, that some horses have but indifferent mouths when they are young, and soon lose their mark ; others have their mouths good for a long time, their teeth being white, even, and regular, till they are sixteen years old and upwards, together with many other marks of freshness and vigour ; but when a horse comes to be very old, it may be discovered by several indications, the constant attendants of age, viz. his gums wear away insensibly, leaving his teeth long and naked at their roots : the teeth also grow yellow, and sometimes brownish. The bars of the mouth, which in a young horse are always fleshy, and form so many distinct ridges, are, in an old horse, lean, dry, and smooth, with little or no rising. The eye-pits in a young horse (except those come of old stallions) are generally filled up with flesh, look plump and smooth ; whereas in an old horse, they are sunk and hollow, and make him look ghastly, and with a melancholy aspect. There are also other marks which discover a horse to be very old, viz. grey horses turn white, and many of them all over flea-bitten, except their joints. This, however, happens sometimes later, and sometimes sooner, according to the variety of colour and constitution. Black horses are apt to grow grey over their eye-brows, and very often over a good part of their face, especially those who have a star or blaze fringed round with grey when they are young. All horses, when very old, sink more or less in their backs, and some horses, that are naturally long backed, grow so hollow with age, that it is scarce possible to fit them with a saddle. Of this kind are several Spanish and Barbary horses, and many of the Danish and Flanders breed. Their joints also grow stiff with old age, and their knees and hocks bend so, that they are apt to trip and stumble upon the least descent, though the way be smooth, and no ways rugged. After which they can be of little use to the owner. *Gibson on Horses.*

AGE of neat cattle, viz. the ox, cow, and bull. The age of these animals is known by the teeth and horns. At the end of ten months they shed their first fore-teeth, which are replaced by others, larger, but not so white ; and in three years all the incisive teeth are renewed. These teeth are at first equal, long, and pretty white ; but as the creatures advance in years, they wear, become unequal, and black. They

They also shed their horns at the end of three years; and these also are replaced by other horns, which, like the second teeth, continue. The manner of the growth of these horns is not uniform, nor the shooting of them equal. The first year, that is the fourth year of the creature's age, two small pointed horns make their appearance, neatly formed, smooth, and towards the head terminated by a kind of button. The following year this button moves from the head, being impelled by a horny cylinder, which lengthening in the same manner, is also terminated by another button, and so on: for the horns continue growing as long as the creature lives. These buttons become annular joints, which are easily distinguished in the horn, and by which the age of the creature may be easily known; counting three years for the point of the horn, and one for each of the joints. *Buffon's Histoire Naturelle, tom. IV.*

AGE of sheep. These animals in their second year have two broad teeth; in their third year they have four broad teeth before; in their fourth year six broad teeth, and in their fifth year eight broad teeth. After which none can tell how old a sheep is while their teeth remain, except by being worn down. *Ellis on Sheep.*

At the end of one year, rams, sheep, and weathers, lose the two fore-teeth of the lower jaw; and they are known to want the incisive teeth in the upper-jaw. At eighteen months the two teeth joining to the former, also fall out; and at three years, being all replaced, they are even and pretty white. But as the creature advances in age, they become loose, blunt, and afterwards black. The age of the ram, and all horned sheep, may also be known by their horns, which shew themselves in their very first year, and often at the birth, and continue to grow a ring annually to the last period of the creature's life. *Buffon's Histoire Naturelle, tom. V.*

AGE of goats. The age of goats is known by the same tokens as those of the sheep, viz. by their teeth, and the annular rings on their horns.

AGRICULTURE, the art of tilling, manuring, and cultivating the earth, in order to render it fertile.

This art claims the precedence of all others in point of antiquity, it having been the sole employment of our first parents in the delightful garden of Eden.

Adam instructed his children in this necessary art, both by precept and example; and we are told by the sacred historian, that Cain applied himself to husbandry, while Abel led the life of a shepherd, and contented himself with feeding his flocks.

After the deluge the descendants of Noah carried with them the art of husbandry, and established it in the various countries where they settled. It was, however, very simple in these early ages, and its advances towards perfection slow and almost imperceptible.

Abraham and the rest of the patriarchs, who had no fixed residence, applied themselves to a pastoral life, enobling, by their example, a profession, which has now for many ages lost its original dignity, from its being practised only by the meaner sort of people. But as soon as their descendants were fixed in Palestine, they all became husbandmen, from the chief of the tribe of Judah, to the lowest branch of the family of Benjamin: birth at that time made no distinction, and agriculture was considered as a very honourable employment.

The Chaldeans, who inhabited the countries where agriculture had its birth, carried that valuable art to a considerable degree of perfection; they cultivated their lands with great assiduity, and enjoyed the pleasing satisfaction of receiving from their fields a very plentiful harvest. The Egyptians, who from the fertility of their country, caused by the annual overflowings of the Nile, raised prodigious quantities of corn, were so sensible of the blessings resulting from agriculture, that they ascribed the invention of it to Osiris; and even carried their superstitious gratitude so far, as to worship those animals that laboured in tilling the ground.

The Phœnicians, so well known in the sacred writings by the name of Philistines, were also famous for their skill in agriculture; but finding themselves too much confined in their native country by the conquests of the Israelites, they spread themselves through the greater part of the islands of the Mediterranean, and carried with them their knowledge in husbandry.

The Carthaginians followed the taste of their ancestors, and applied themselves assiduously to the study of agricul-

ture. Mago, their famous general, wrote no less than twenty-eight books on that subject, and which Columella tells us were translated into Latin by an express decree of the Roman senate. Servius adds, that Virgil used these books as a model when he wrote his *Georgics*.

The ancients tell us, that the goddess Ceres was born in Sicily, where she invented the art of sowing corn, and the tillage of land. The meaning of this fable is very evident; that island was very fruitful in corn, and agriculture was there esteemed so honourable an employment, that even their kings did not disdain to practise it with their own hands.

But time, which at first gave birth to arts, often caused them also to be forgotten, when they were removed from the place of their origin. The children of Noah, who settled in Europe, doubtless carried with them the knowledge of agriculture; but their descendants, who took possession of Greece, were such a savage race, that they fed on herbs, after the manner of beasts. Pelasgus taught them the culture of the oak, and the use of acorns as food, for which divine honours were paid him.

The Athenians, who were the first that received any tincture of politeness, taught the use of corn to the rest of the Greeks; they also taught them the manner of cultivating the ground, and preparing it for seed. The Greeks soon perceived that bread was more wholesome, and its taste more delicate than acorns; and accordingly thanked the gods for such an unexpected and beneficial present. After this the Athenian kings thinking it more glorious to govern a small state wisely, than to aggrandize themselves by foreign conquests, withdrew their subjects from war, and employed them solely in cultivating the earth. This constant application carried agriculture to a considerable degree of perfection, and soon reduced it into an art.

Hesiod, who is generally thought to have been contemporary with Homer, was the first among the Greeks who wrote on this subject. He calls his poem "Works and Days;" because agriculture requires exact observations of times and seasons.

The other eminent Greek writers upon agriculture, are Democritus of Abdera, Socraticus, Xenophon, Tarentinus, Architas, Aristotle, and Theophrastus, from whom the art received considerable improvements; as also from Hieron, Epicharmus, Philometer, and Attalus.

The old Romans esteemed agriculture so honourable an employment, that in the earliest times of the republic, the highest praise that could be given a man, was to say of him, that he cultivated well his own spot of ground. The most illustrious senators applied themselves to this profession; nor had they either splendor or majesty, but when they appeared in public. And their greatest generals, at their return from the toils of war, from taking of cities, and subduing of nations, were impatient till they were again employed in cultivating their lands, and thought it no disgrace to follow the plough, though they were at the same time prepared to serve the wants of the republic, attend her councils, or put themselves at the head of her armies.

It must indeed be allowed, that when the Romans became tainted with the luxury of Asia, they gradually lost the noble simplicity of their ancestors, and employed their slaves in the severer labours of a country life. But though they did not themselves hold the plough, yet even men of consular dignity looked upon it as a reward for their public services, when they obtained leave to retire into the country, and were equally respected when overlooking their farms, as when seated in the chair of magistracy. M. Cato, the Censor, that illustrious Roman general, orator, politician, and lawyer, after having governed provinces, and subdued nations, did not think it below his station to write a large treatise on agriculture.

This work, according to Servius, was dedicated to his own son, and was the first Latin treatise on that subject. This work, has been handed down to us in all its purity, in the same manner as Cato wrote it. Varro composed a treatise on the same subject, and on a more regular plan. This work is embellished with all the Greek and Latin erudition of that learned author.—Agriculture also received great improvements from the two Salsernæ, and likewise from Scorsus, Tremellius, and M. Terentius. Virgil has adorned it with the language of the muses, and given it majesty by his verse. He has finely embellished the precepts of husbandry left by Hesiod and Mago.

Columella, who flourished in the reign of the emperor Claudius,

Claudius, wrote twelve books on husbandry. He was a native of Bœtica in Spain, and had devoted his time to the study of husbandry.

From this time till the reign of Constantine IV. husbandry continued in a declining state, when that wise emperor caused a large collection of the most useful precepts relating to agriculture to be extracted from the best writers, and published under the title of *Geoponics*.—Some say he made this collection with his own hand. Nor is this at all improbable, as it is well known, that after he had conquered the Saracens and Arabians, he not only practised, but studied the arts of peace, fixing his chief attention on the advancement of husbandry.

But from the time of Constantine IV. till about the year 1478, agriculture lay in a kind of dormant state, when Crescenzi published an excellent performance on agriculture at Florence. He was soon followed by several of his countrymen, among whom Tatti, Stefano, Augustino Gallo, Sanfovino, Lâuro, and Tarello, deserve particular honour.

In the mean time Fitz-Herbert, judge of the Common Pleas, shone with unrivalled lustre in the practical parts of husbandry. He published two treatises on this subject; the first, which was entitled, *The Book of Husbandry*, appeared in 1534, and the second, called, *The Book of Surveying and Improvements*, in 1539.

Fitz-Herbert's books of agriculture soon raised a spirit of emulation in his countrymen, and many treatises of the same kind successively appeared; but time has deprived us of many of those writings, or at least they are become so very scarce, as only to be found in the libraries of the curious.

About the year 1600, France made some considerable efforts to revive husbandry, as appears from several large works, particularly *Les Moyens de devenir Riche*, and the *Cosmopolite*, by Barnard de Palissy, a poor potter; *Le Theatre d'Agriculture*, by de Serres; *L'Agriculture & Maison Rustique*, by Messrs. Etienne and Liebault, &c.

The Flemings, about the same period, dealt more in the practice of husbandry, than in publishing books on the subject; so that their attention doubtless was to carry on a private lucrative trade, without instructing their neighbours: and hence it happened, that whoever was desirous of copying their method of agriculture, was obliged to travel into their country, and make his own remarks. The principal, and indeed just, idea of husbandry consisted in this, namely, to make a farm resemble a garden as near as possible. Such an excellent principle at first setting out, led them of course to undertake the culture of small estates only, which they kept free from weeds, continually turning the ground, and manuring it plentifully and judiciously.

When they had by this method brought the soil to a proper degree of cleanliness, health, and sweetness, they ventured chiefly upon the culture of the more delicate grasses, as the surest means of acquiring wealth in husbandry upon a small estate, without the expence of keeping many draught horses or servants.

A few years experience was abundantly sufficient to convince them, that ten acres of the best vegetables for feeding cattle, properly cultivated, would maintain a larger stock of grazing animals, than forty acres of common farm grass. They also found that the best vegetables for this purpose were lucern, saintfoin, trefoil of most denominations, sweet fenugreek, buck and cow-wheat, field turnips, and spurrey.

The political secret of their husbandry, therefore, consisted in letting farms on improvement. They also discovered eight or ten new sorts of manure. They were the first among the moderns who ploughed-in living crops for the sake of fertilising the earth, and confined their sheep, at night, in large sheds built on purpose, whose floors were covered with sand or virgin earth, &c. which the shepherd carted away every morning to the compost dunghill.

Our fatal domestic wars, during the reign of Charles I. changed the instruments of husbandry into martial weapons; but after the death of that unfortunate monarch, artful and avaricious men crept into the confiscated estates of the nobility, gentry, and clergy; and as many of these new encroachers had risen from the plough, so they returned with pleasure to their old profession, being chiefly animated by the love of gain. Plattes, Hartlib, Blythe, and others, seized this favourable disposition of the common people, and encouraged it by writings, which have since had few equals; nor was Cromwell wanting to lend his assistance.

Sir Hugh Platt was one of the most ingenious husbandmen of the age in which he lived; yet so great was his modesty, that all his works, except his *Paradise of Flora*, seem to be posthumous. He held a correspondence with all the lovers of agriculture and gardening in England; and such was the justice and modesty of his temper, that he always named the author of every discovery communicated to him. Perhaps no man, in any age, discovered, or, at least, brought into use, so many new sorts of manure. Witness his account of the compost and covered dunghill, and his observations on the fertilising qualities lodged in salt, street-dirt, and the fullage of streets in great cities, clay, fuller's-earth, moorish earth, dung-hills made in layers, fern, hair, calcination of all vegetables, malt-dust, willow-tree earth, soap-boiler's ashes, marle, and broken pilchards.

Gabriel Plattes may be esteemed an original genius in husbandry. He began his observations in the time of queen Elizabeth, and continued them through the reigns of James I. Charles I. and during the first three or four years of the commonwealth. But notwithstanding the great merit of this writer, the public suffered him to starve and perish in the streets of London; nor had he a shirt upon his back when he died.

Samuel Hartlib, a celebrated writer on husbandry in the last century, was highly beloved and esteemed by Milton, and other great men of that time. In his preface to a work commonly called his *Legacy*, he laments that no public director of husbandry was established in England by authority; and that we had not adopted the Flemish method of letting farms upon improvement. This remark of Hartlib procured him a pension of one hundred pounds a year from Cromwell; and the writer afterwards, the better to fulfil the intention of his benefactor, procured Dr. Beati's excellent annotation on the *Legacy*, with other valuable pieces from his numerous correspondents.

About the time when this author flourished seems to have been an æra when the English husbandry rose to great perfection; for the preceding wars had made the country gentry poor, and, in consequence thereof, industrious. They found the cultivation of their own lands to be the most profitable post they could occupy. But a few years after, when the Restoration took place, all this industry and knowledge were exchanged for dissipation and heedlessness; and then husbandry passed almost entirely into the hands of farmers.

The famous work attributed to Hartlib, and called the *Legacy*, was only drawn up at Hartlib's request; and, after passing through his correction and revision, was published by him. The real author of this treatise was R. Child. It consists of one general answer to the following question, namely, "What are the actual defects and omissions, as also the possible improvements, in English husbandry?"

Several other pieces on husbandry followed the publication of the *Legacy*, and greatly improved that necessary and useful art.

The first writer that inspired his countrymen with a desire of reviving the study of agriculture after the Restoration, was Evelyn; who, being followed by the famous Tull, opened a new sphere for the minds of mankind to range in; and since this period several valuable improvements have been made in the English husbandry, by a great variety of authors.

Ireland, about the middle of the last century, began to make no inconsiderable figure in the art of husbandry. It must, indeed, be confessed that Ireland had very strong prejudices in behalf of a very wretched method of agriculture, till about the middle of the last century, when Blythe opened the eyes of that people by his incomparable writings. Since which a certain spirit of improvement has, more or less, been promoted and carried on with great zeal and constancy by the nobility, clergy, and gentry of that kingdom. In proof of which it will be sufficient to observe, that the transactions of the Dublin society for encouraging husbandry, are now cited by all foreigners in the *Memoirs* relating to that subject.

After the peace of Aix-la-Chapelle, almost all the nations of Europe, by a sort of tacit consent, applied themselves to the study of agriculture; and continued to do so, more or less, amidst the universal confusion that soon succeeded. The French found, by repeated experience, that they could never maintain a long war, or procure a tolerable peace, without they raised corn enough to support themselves in such a manner as they should not be obliged to submit to harsh terms on the one hand, or perish by famine on the other. Their king, therefore, thought proper to give public encourage-

encouragement to agriculture, and has even been present at the making of several experiments. The great and rich, of various ranks and stations, followed this example, and the very ladies put in for their share of fame in this commendable undertaking. Even during the hurry and distresses of the last war, some attention was paid to agriculture. Prize questions were then proposed annually in rural academies, particularly at the two academies of Lyons and Bourdeaux. And many alterations were made by the society for improving agriculture in Britany.

Since the conclusion of the peace, matters have been carried on with great vigour. The university of Amiens has made various proposals to the public for the advancement of husbandry; while the marquis de Tourbilly, a writer who proceeds chiefly on experience, has the principal direction of a Georgical society, lately established at Tours.

The society of Rouen also deserves our notice; the archbishop of the diocese is one of the members.

We shall only add on this subject, that there are at present societies existing in France, established by royal approbation, for the promoting of agriculture; and these thirteen societies have nineteen co-operating societies belonging to them, whenever it happened that a district was too large to be effectually taken care of by one society.

The art of agriculture is, at present, publicly taught both in the Swedish, Danish, and German universities, where the professors may render effectual service to their respective countries, if they understand the practical as well as the speculative parts, and can converse to as much advantage with the farmer and peasant, as with Virgil and Columella.

Nor has Italy been inactive. The Neapolitans of the present age have condescended to return back to the first rudiments of revived husbandry, and begun to study afresh the agriculture of Crescenzo, first published in the year 1478. The people of Bergamo have pursued the same track, and given the world a new edition of the *Ricardo d'Agricoltura di Tarello*, which was originally published at Mantua in 1577.

The duchy of Tuscany has imbibed the same spirit. A private gentleman left his whole fortune to endow an academy of agriculture. Even Ferrara, a small territory in the papal dominions, has contributed its just contingent, and made some laudable attempts in husbandry.

Animated with a desire that the people, under his government should excel in husbandry, his Sardinian majesty sent subjects to learn the practice of foreign countries, and made several attempts to establish a better method of agriculture among his subjects.

In Poland, where a natural fertility of soil seems to dispense with the necessity of calling in improvements, Mr. de Bieleuski, grand-marshal of the crown, made abundance of successful attempts to introduce the new husbandry among his countrymen, and procured the best instruments for that purpose from France and other parts of Europe.

The Hollanders give little attention to agriculture, if we except one single collateral instance, namely, the draining of fens and morasses; and even that has proceeded more from the motive of self-preservation, than any particular turn towards husbandry.

In the year 1759, a society established itself at Berne, in Switzerland, for the advancement of agriculture, and rural oeconomies. That society consists of many ingenious private persons, and also of some of great weight and influence in the republic; most of them men of a true cast for the improvement of husbandry, being enabled to join the practice with the theory. They published several useful pieces, which we have inserted under their proper heads.

We must not omit to mention here, that Linnaeus and his disciples performed great things in the north of Europe, particularly in discovering new, profitable and well-tasted food for cattle. At the same time Sweden has bestowed successful labours on a soil, which was before looked upon as cold, barren, and incapable of melioration; of this the memoirs published at Stockholm will be a lasting monument.

Denmark, as well as many courts in Germany, follow the like example. His Danish majesty encourages, in particular, the woollen manufacture; and the late king sent three persons into Arabia Felix, to make remarks, and bring over such plants and trees as may be useful in husbandry, building, &c.

At the same time the duchy of Wirtemberg, a country

no ways unfavourable to corn and pasturage, has not failed to contribute its assistance towards the improvement of agriculture, having some time ago communicated to the public its oeconomical relations from the press at Stuttgart.

Nor have the learned of Leipzig and Hanover been inattentive to this great art of supporting human kind, and that amidst all the rage and devastations of war; witness the *Journal d'Agriculture*, printed at Leipzig, and the *Recueil d'Hanovre*, printed at that city.

Even Spain, naturally inactive on these occasions, in spite of all the prejudices of a bigoted religion, invited Linnaeus, with the offer of a large pension, to superintend a college, founded for the sake of making new enquiries into the history of nature, and the art of agriculture.

But England alone exceeds all modern nations in husbandry; and there is reason to hope, from the spirit that now animates a great number of the nobility and gentry, that this useful art will, in a few years, be carried to a much greater degree of perfection than it ever yet reached in any age or country. The respectable patriots that form the society established at London, for the encouragement of arts, seem determined to contribute all that lies in their power towards the advancement of agriculture. They have already done much, and there is reason to hope they will do more. A vast variety of different machines for facilitating the practice of agriculture, have been sent them in consequence of their large premiums and bounties. Such munificence and attention to public prosperity may be truly called royal, as it would cast a lustre on the greatest monarch that ever swayed a sceptre. The late institutions of societies in different parts of the kingdom for agriculture, and the professorship of agriculture lately established at Edinburgh, cannot but promote the study, and point out the utility of it. We shall conclude this history, with observing, that the reader will find, under the proper articles, a more minute account of the various improvements that have been lately made in the different parts of Europe.

AGRIMONY, a troublesome perennial plant in pasture grounds. It has generally a single, round, rough stalk, with leaves placed alternately upon it, which are winged with smaller leaves placed between the larger pairs. The yellow flowers grow alternately along the stalk, in a long row, after the manner of a spike, and are succeeded by rough seeds.

AGROSTIS CORNUCOPIA, or new American grass, introduced into England lately. It was first introduced into Georgia, where it continues to flourish; and is found better than any other grass for running amongst the rocks, and standing drought; but its chief excellence is, that not only cattle, horses, and sheep fatten upon it, but every species of poultry are fond of it. It is greatly favourable for making of grass plats, being of a fine texture, and a beautiful verdure in this country throughout the year. The following experiments were made by Mr. Frazer at Chelsea. A few seeds sown Nov. 20, 1788, continued dormant all the winter. The plants made their appearance in the beginning of March. Flowered early in September, when they measured from three to four feet. Each root produced one hundred stems: each stem sending forth branches, some from four to six, others as far as ten or twelve, bearing panicles for seed; each panicle from twelve to eighteen inches long. This shews the multiplication to be infinite. A small quantity was sown March 15, 1789. Seedlings transplanted, by dividing the roots on the 22d of May; began unexpectedly to flower in September, and completed their flowers nearly as early as those sown in November preceding. On the 9th of September, measured two feet five inches. Part of the bed cut close to the ground on the 15th of August, measured, on the 9th of September, from twelve to sixteen inches; and on the 10th of October twenty-two inches. The sward much thicker than what had not been cut down. It then began to flower, from 100 to 200 panicles on each root.

Having cleaned a cask of seed accidentally about the middle of April following, in a little hard gravelly court, about a month afterwards, to my surprise, I found the grass coming up very thick; and it has continued in as flourishing a state as any I have sown in the garden.

Apprehending that the success in the gravelly court was chiefly owing to the seeds not being buried in the ground, on the 15th of May I took a four-inch board, and laid out with it four drills twenty feet long, pressing down the board in the drills so as to render the surface smooth and hard. I then took a gill of the seed and mixed it with a

Agrostis Cornucopiae or
new American grass

peck of mould and foot, and sowed it in the drills, without any other covering. A very fine crop was the consequence. On the 10th of October, it measured twenty-two inches high, and contained plants sufficient to occupy half an acre. Same day sowed four rows in the manner of mustard and cresses, about half an inch deep in the ground, covering it with mould. No plants came up.

From these experiments I concluded, that the proper management of this grass is, that the ground should be in extremely fine tilth, well cleaned, harrowed, and rolled with a heavy roller, before the seed is sowed. A quart of seed to be mixed with a bushel of light earth and foot.

On the 10th of October, I cut down a patch of grass, which had been sowed on the fourth of June. It measured twenty-seven inches. The part so cut down measured, on the first of November, twenty days after it was cut, nine inches. One seedling plant was divided the 22d of May into 200, and which were transplanted out, and cut down the 15th of August, measuring then twenty inches: one of these plants so transplanted was taken up in the presence of a gentleman on the 10th of October, and divided into 201 plants, and planted into a bed; notwithstanding so late in the year, they are flourishing. The above-mentioned seedling has, at this rate, multiplied itself into 4000 plants in five months. It might have been multiplied into double or treble this number, by dividing the joints, as it propagates from them as well as by the root.

The greatest part of the above experiments have been made in a garden, for want of a field to try them in: this, however, is equally conclusive as if it had been in a field, as the garden is a poor gravelly soil.

There is nothing now remains fully to ascertain the great importance of this discovery, but to observe the effects of the winter on it in this country. And as it is now ascertained to be a native of Canada, there can be little doubt that it will not be injured by the frosts in this climate; for the roots strike very deep in the ground; a circumstance which cannot fail to protect it during the severest frost that can happen in winter, as well as the greatest drought in summer.

Mr. Frazer, in Feb. 1790, proceeds to give a farther account of this grass, when he says it looks more like wheat in the month of May, than any thing else I can compare it to; some of the plants sown early in March, measure three feet; one root has produced a hundred stems, from each of which branches, six or seven panicles for seed, some of which panicles measures upwards of eighteen inches long. Part of the above I transplanted the 22d of May, and cut close to the ground the 15th of August, and then measured two feet five inches; that part which was cut is now twenty inches high, and what appears to me extraordinary, there is a shew of about 200 panicles on each root, and forms a thick swarth, and a much finer blade than that which was not cut. On the 10th instant, one of the said roots was taken up in the presence of Mr. Hudson, author of the *Flora Anglica*, which was divided into 201, and was transplanted six inches apart, in order to observe what progress it might make in the course of the winter. See Plate I.

AIR, that thin, dilatable, and compressible body in which we breathe, and which surrounds the earth to a great height.

The air, besides its various other uses, is a principal cause of the vegetation of plants; an instance of which we have from Mr. Ray, in the Philosophical Transactions, of lettuce-seed, that was sown in the glass receiver of the air-pump, which was exhausted, and cleared from all air, which grew not at all in eight days time; whereas some of the same seed, that was sown at the same time in the open air, was risen to the height of an inch and an half in that time; but the air being let into the exhausted receiver, the seed grew up to the height of two or three inches in the space of one week.

Another instance of the usefulness of the air in vegetation, is the sedum, which will push out roots without earth and water, and live for several months: and some sort of aloes, if hung up in a room entirely secured from frosts, will remain fresh for some years, though they will sensibly lose in their weight. Air is capable of penetrating the porous and spongy parts of plants, and being there contracted, of dilating itself again.

The air operates also within the bowels of the earth, and by its subtilty perspiring through the pores, assists in the

rarefaction, of the crudities of the earth, and in the dispelling all superfluous moisture, entering into the very pores and veins of the trees, plants, herbs, &c. carrying along with it those salts contained either in itself, or lodged in the earth: which salts or juices are altered according to the several figures or dimensions of the different strainers or vessels of those several plants which grow upon the same spot of earth, which is so impregnated with these salts: and thence those varieties in taste and smell proceed, notwithstanding they all receive their nourishment from the same stock that is lodged in the earth.

The air also affects the branches, leaves, and flowers of trees, plants, and herbs, entering and perspiring through them, and even through the bark and body of trees: and by the same kind of subtilty it does, by its refreshing breezes, moderate the intenseness of the sun-beams, cooling, clearing, blowing, opening, and extending all the offspring of nature. The air fixes and insinuates its aerial substance into the liquid sap of vegetables: and, as all the agitations in nature proceed from the contrariety of parts inhabiting together, in this aerial and liquid substance, being mixed, cause the agitation and motion in vegetables; or, more properly, set it all into a ferment, whether it be in the roots, or in the stem; and it rises by co-operation of the sun, which is the third agent in vegetation, up to the top of a tree, &c. as liquids rise by fire to the top of the containing vessel.

The air, we find, produces a vibratory motion in several bodies; and, particularly in plants, the air-vessels thereof perform the office of lungs: for the air contained in them sometimes contracting, and sometimes expanding, according as the heat is increased or diminished, presses the vessels, and eases them again by turns; and thus promotes a circulation of their juices, which could scarce be otherwise effected.

Air, says the learned Dr. Hales, is a fine elastic fluid, with particles of very different natures floating in it, whereby it is admirably fitted by the great author of nature, to be the breath or life of vegetables, as well as animals, without which they can no more live nor thrive than animals can. As a proof of the great quantities of air in vegetables, he refers to the third chapter of his excellent Treatise of Vegetable Statics, where he says, in the experiments on vines, the great quantities of air was visible, which was continually ascending through the sap into the tubes: which manifestly shews what plenty of it is taken in by vegetables; and is perspired off with the sap through the leaves.

He adds several experiments, as to an apple-branch, apricot-branch, birch, and other plants, to prove the same thing.

And Dr. Grew has observed, that the pores are so large in the trunks of some plants, as in the better sort of thick walking canes, that they are visible to a good eye without a glass; but, with a glass, the cane seems as if stuck at top full of holes with great pins, so large as very well to resemble the pores of the skin in the ends of the fingers, and ball of the hand.

In the leaves of pines, they likewise, through a glass, make a very elegant shew, standing almost exactly in rank and file, through the length of the leaves. Whence it may be thought probable, that the air freely enters plants, not only with the principal fund of nourishment by the roots, but also through the surface of their trunks and leaves, especially at night, when they are changed from a perspiring, to a strongly imbibing state.

Dr. Hales likewise tells us, that in all those experiments that he tried to this purpose, he found that the air entered very slowly at the bark of young shoots and branches, but much more freely through old bark; and that in different kinds of trees it had different degrees of more or less free entrance.

And likewise, that there is some air both in an elastic and unelastic state, mixed with the earth (which may well enter the roots with the nourishment) he found by several experiments which he gives in the abovementioned treatise.

The excellent Mr. Boyle, in making many experiments on the air, among other discoveries, found, that a good quantity of air was producible from vegetables, by putting grapes, plums, gooseberries, peas, and several other sorts of fruits and grain, into exhausted and unexhausted receivers, where they continued for several days emitting great quantities of air.

This

This put the curious Dr. Hales upon further researches to find out what proportion of air he could obtain out of the vegetables in which it was lodged and incorporated; and, from a vast variety of curious and accurate experiments, concludes, that air abounds in vegetable substances, and bears a considerable part in them: and, that if all parts of matter were only endowed with a strongly attracting power all nature would then become one unactive cohering lump.

Wherefore it was absolutely necessary, in order to the actuating this vast mass of attracting matter, that there should be every where mixed with it a due proportion of strongly repelling elastic particles, which might enliven the whole mass, by the incessant action between them and the attracting particles.

And since these elastic particles are continually in great abundance reduced by the power of the strong attractors, from an elastic to a fixed state, it was therefore necessary that these particles should be endued with a property of resuming their elastic state, whenever they were disengaged from that mass in which they were fixed, that thereby this beautiful frame of things might be maintained in a continual round of the production and dissolution of vegetable as well as animal bodies.

The air is very instrumental in the production and growth of vegetables, both by invigorating their several juices, while in an elastic active state, and also by greatly contributing, in a fixed state, to the union and firm connection of the several constituent parts of those bodies, viz. their water, fire, salt, and earth.

To conclude, by reason of those properties of the air before-mentioned, it is very serviceable to vegetables, in that it collects up and breaks open the clouds, those treasures of rain, which nourish the vegetable tribe.

The air also helps to waft or disperse those foggy humid vapours which arise from the soil, and would otherwise stagnate and poison the whole face of the earth.

The air, by the assistance of the sun, assumes and sublimates those vapours into the upper regions; and these foggy humid vapours are, by this sublimation, and the coercive power of the air and sun, rarefied, and made again useful in vegetation.

On the contrary, the air, which in so many ways is subservient to vegetables, is also, upon some accounts, injurious and pernicious to them; not only to the ligneous, herbageous, and flowery parts above, but also to the roots and fibres below the earth: for as the air penetrates deep into the soil, it is natural to conclude, that a dry, husky, scorching air, may be very prejudicial to the tender fibres of new planted vegetables.

ALDER-TREE, the name of a tree very common in most parts of England. It hath male and female flowers, which are produced at remote distances on the same plant; the male flowers are digested into a long juli or catkin, which is loose, imbricated, and cylindrical. The female flowers are collected into a conical scaly head, and are succeeded by scaly cones.

These trees delight in a moist soil, where few other trees will thrive; they are propagated either by layers, or planting of truncheons about three feet in length. The best time for this is in February, or the beginning of March; these should be sharpened at one end, and the ground loosened with an instrument before they are thrust into it; lest, by the stiffness of the soil, the bark should be torn off, which may occasion their miscarriage. These truncheons should be thrust into the earth two feet at least, to prevent their being blown out of the ground by strong winds, after they have made stout shoots. The plantations should be cleared from all such weeds as grow tall, otherwise they will overbear the young shoots; but when they have made good heads, they will keep down the weeds, and will require no further care.

If you raise them by laying down the branches, it must be performed in October; and by the October following, they will have taken root sufficient to be transplanted out; which must be done by digging a hole, and loosening the earth in the place where each plant is to stand, planting the young trees at least a foot and a half deep, cutting off the top to about nine inches above the surface, which will occasion them to shoot out many branches.

The distance these trees should be placed, if designed for a coppice, is six feet square; and if the small lateral shoots are taken off in the spring, it will very much strengthen your upright poles, provided you leave a few small shoots at distances upon the body thereof, to detain the sap for the encrease of its bulk.

These trees may be also planted by the side of brooks, as is usual for willows, where they will thrive exceedingly, and may be cut for poles every fifth or sixth year. This wood is in great request with the turners, and will endure a long time under ground; or to be laid in water. *Miller's Gard. Dict.*

Alder makes an extraordinary fence against rivers and streams, and preserves the banks from being undermined by the water; because it is always sending suckers from the lowest roots, which makes it very useful, where streams wear away the banks, and are widening their course. *Mortimer's Husbandry.*

Alder has one peculiar and beneficial property, namely, that no beast will crop it, be it young or old, which saves the great charge of fencing it after planting. *Ellis's Timber Tree improved.*

Mr. Marshall, in his Rural Economy of Norfolk, says, the alder is observed to make the ground it grows on still more boggy; and therefore ought for two reasons never to be planted; namely, the injury to the land; and its own trifling value. He again says, it is a great nuisance in meadows, and not only encumbers the spot it grows on, but is allowed on all hands to render moory soils still more rotten. It is a vile inhabitant even in the neighbourhood of a meadow; for its seeds being blown about by the wind, are trodden by cattle into the soil, where, springing up among the herbage, embitter the grass and render it unpalatable to the stock.

ALLEY, in the new husbandry, implies the vacant space between the outermost row of corn on one bed, and the nearest row to it on the next parallel bed. *See BED.*

The practice of the new husbandry has already sufficiently shewn, that too narrow alleys would hardly answer any of the ends for which they are intended; and, on the other hand, the making them too wide is a loss of ground. About four feet, exclusive of the spaces or partitions between the rows of corn in the beds, is a good middling breadth.

It is not indeed necessary to make the alleys quite so wide in good soils: an intelligent husbandman will easily judge what breadth is most proper. But what greatly merits the attention of every one, and ought never to be lost sight of, is, that wide alleys are more easily and much better stirred than those which are narrower: for when an alley is wide, the large furrow in the middle of it may be cut deep, there being then sufficient room to turn the earth over towards the rows; while, on the other hand, the earth, in too narrow alleys, cannot be stirred deep enough, nor can room be found for what is turned over out of the furrows, without danger of burying great part of the rows.

We will, therefore, suppose the general breadth of the alleys to be about four feet; but the whole of that breadth is not to be ploughed or stirred, either with the plough or cultivator, as soon as the field is sown. Neither of these instruments ought to go too near the rows of corn, for fear of rooting up the plants; but a slip of earth about six inches wide should be left untouched on the outside of each bed; by which means the part of the alley that is to be stirred, will be reduced to the breadth of three feet; and even that is lessened in the first ploughing before winter by a deep furrow which is then cut close to, and all along those six inch slips, and the earth taken out of each furrow is thrown into the great furrow in the middle of the alley, which it serves to fill and arch up. These two side furrows make together a breadth of about eighteen inches, and consequently leave, in the middle of the alley, a breadth of about eighteen inches more, on which is heaped up the earth thrown out of the two furrows: and thus the alleys remain all the winter.

The first hoeing in the spring should turn the earth, heaped up in the middle of the alleys, back towards the rows of corn. The two furrows that were opened before winter are then filled up, and a new one is cut in the middle of the alley.

To perform the first hoeing with the common plough, which may be very easily done, two turns of that instrument will be requisite, namely, one on each side of the alley, as near as possible to the beds. But as these two turns will not be always sufficient to form the furrow perfectly, a great deal of earth frequently remaining between it and the bed, a third turn of the plough becomes often necessary; and sometimes a fourth, to hollow the middle furrow as it ought to be.

If this work be performed with the cultivator with two mould-boards, the instrument must be placed in the middle of the alley, and the horses in one of the two furrows. The share

share will easily enter a great depth into the earth, which was laid there by the last hoeing before winter: and as the horses advance, that great ridge of earth will be divided into two parts, which will be turned over into, and fill up the furrows that were made before winter, on each side of the alley, close to the beds. See the article CULTIVATOR.

Thus the great furrow in the middle of the alley will be opened, and the whole operation performed by one turn of the cultivator. The earth thus turned over will be thoroughly stirred, and so much time and labour will be saved by this method, that the farmer may easily afford one or two stirrings more in the summer, which will always be of great service. *M. de Chateaufieux.*

Wheat, in the new husbandry, is usually cultivated upon ridges of about four feet nine inches broad, and upon these ridges are drilled two rows of wheat, ten inches asunder, the distance therefore between these double rows is near four feet; this distance, which *M. de Chateaufieux* here calls the alleys, was, by *Mr. Tull*, called the intervals, and the distances of the two rows of wheat upon the ridges he called partitions.

He at first made his ridges six feet broad, and drilled three or four rows upon each ridge; but upon further experience he found, that two rows upon a ridge of four feet nine inches broad, produced better crops than three or four rows upon six feet ridges, and he recommends these double rows to those who would cultivate wheat with the hoe-plough.

It is likewise observable, that though in his early practice of horse-hoeing wheat, he was cautious of bringing the hoe-plough very near the rows, he found afterwards that there was no danger in hoeing close on the rows of corn, but, on the contrary, the crop was much improved by it, and that the plough in hoeing the earth from the rows, could not be brought too close to them, unless it tore out any of the plants, inasmuch, that he says he could bring the plough within about an inch of the rows when the earth was in right temper for it.

The reason that *M. de Chateaufieux* directs, as above, that the hoe-plough should not come close to the rows by six inches, was because he had not then seen *Mr. Tull's* last Improvements upon the Hoeing Culture, which was not published till several years after the first parts of the horse-hoeing husbandry was translated into French.

The first horse-hoeing of the wheat is performed in the beginning of winter, and the earth is ploughed away from the rows into the intervals, which forms small ridges in the middle between the double rows. The second hoeing is in the spring, which turns the back to the rows. The third hoeing is from the rows after the wheat has blossomed; this turns the earth into the intervals, forming small ridges there as at the first hoeing. The fourth hoeing returns the earth to the ridges, which is performed a month or more after the third hoeing: this commonly finishes the horse-hoeings if the land is in good heart, otherwise one or two more hoeings are necessary. The double mould board plough is useful to clear the furrows, and lay all the earth up in ridges after the last hoeing, but no cultivators should be substituted in room of the hoe-plough.

ALMOND-TREE, is generally cultivated in gardens for the beauty of its flowers. These often appear in February, when the spring is forward; but if frost comes on after the flowers appear, their beauty will be of short duration, and in those seasons few almonds are produced; whereas when the trees do not flower till late in March, they seldom fail to bear plenty of fruit; many of which will be very sweet, and fit for the table when green, but they will not keep long.

Almond trees are propagated by inoculating a bud of these trees into a plum, almond, or peach-stock, in the month of July. The next spring, when the buds shoot, you may train them up, either for standards, or suffer them to grow for half standards, according to your own fancy.

The best season for transplanting these trees, if for dry ground, is in October, as soon as the leaves begin to decay; but for a wet soil, February is much preferable: observe always to bud upon plum-stocks for wet grounds, and on almond or peach-stocks for dry. *Miller's Gard. Diet.*

AMBERVALIA, a ceremony practised by the ancient Romans, in order to procure from the gods a happy harvest.

This ceremony consisted of a procession in which the victims were conducted thrice round the corn fields before

they were sacrificed. Twelve priests walked at the head of the procession, which consisted of all the neighbouring inhabitants, every one being crowned with leaves of oak, and singing hymns in honour of Ceres, the goddess of corn.

AMBLE, a peculiar kind of pace, wherein a horse's two legs of the same side move at the same time.

In this pace the horse's legs move nearer the ground than in the walk, and, at the same time, are more extended: but what is most singular in it is, that the two legs of the same side, for instance, the off hind and fore-leg, move at the same time; and then the two near legs, in making another step, move at once; the motion being performed in this alternate manner, so that the two sides are alternately without support, or any equilibrium between the one and the other, which must necessarily prove very fatiguing to the horse, being obliged to support himself in a forced oscillation, by the rapidity of a motion, in which his feet are scarcely off the ground. For if in the amble he lifted his feet as in the trot, or even in a walk, the oscillation would be such, that he could not avoid falling on his side, and it is only by keeping his feet very near the ground, and by the quick alternate motion that he supports himself in this pace, in which the hind leg is not only to move at the same time with the fore-leg of the same side, but also to gain on it, or touch the ground a foot, or a foot and a half, beyond the spot where the latter grounded. The further the hind-leg extends beyond the place where the fore-leg grounded, the better the horse ambles, and the whole motion is proportionally faster. Thus the whole difference between the amble and the trot consists in this, that the two legs moving together in the latter are in a diagonal position, whereas, in the former, the two legs of the same side move together.

This pace, which is very fatiguing to the horse, is very easy to the rider. It has not the roughness of the trot, which is caused by the resistance of the fore-leg, at the lifting up of the hind; because, in the amble, this fore-leg is lifted up at the same time with the hind-leg of the same side; whereas, in the trot, the fore-leg of the same side is at rest, and resists the impulse during the whole time that the hind leg is in motion.

They who are skilled in horsemanship tell us, that horses which naturally amble, never trot, and that they are a great deal weaker than others. Colts, indeed, very often move in this manner, especially when they exert themselves, and are not strong enough to trot or gallop. Most good horses, which have been over-worked, and on the decline, are also observed voluntarily to amble, when forced to a motion swifter than a walk.

The amble may, therefore, be considered as a defective pace, not being common, and natural only to a very few horses, which, in general, are weaker than others. Add to this, that such amblers as seem the strongest, are spoiled sooner than those which trot or gallop. *Buffon's Histoire Naturel, tom. IV.*

There are various methods of discipline for bringing a young horse to amble: some chuse to toil him in his foot pace through new ploughed fields, which naturally inures him to the stroke required in the amble; but this disorderly toil is very apt to weaken, and sometimes to lame a young horse. Others attempt it by stopping him in a gallop, or trot; so that by losing both, he necessarily stumbles on an amble; but this is apt to spoil a good mouth and rein, and exposes the horse to the danger of an hoof reach, or sinew strain, by over-reaching, &c.—Some prefer ambling by weights as the best way, and in order to do this, either overload the horse with excessive heavy shoes, or fold thick pieces of lead about the fetlock pasterns, without considering that the former are apt to make him interfere, or strike short with his hind-feet; and that the latter, besides that mischief, expose the horse to incurable strains, crushing of the coronet, breeding of ring-bones, &c. Others load the horse with earth, lead, &c. which often occasion a swaying of the back, overstraining of the fillets, &c. Some endeavour to make him amble in hand, before they mount his back, by means of some wall, smooth pale or rail, and by checking him in the mouth with the bridle-hand, and correcting him with a rod on the hinder hoofs, and under the belly, when he treads false; but this is very apt to spoil a spirited horse, even before he can understand what you would have him do.

The best method seems to consist in trying with your hands, by a gentle and deliberate racking and thrusting of the horse forwards, by helping him in the weak part of his

mouth with your snaffle, which must be smooth, big, and full; and correcting him first on one side, then on the other, with the calves of your legs, and sometimes with a spur. If you can by this means make him fall readily into an amble, though in a shuffling and disorderly manner, much labour will be saved; for that aptness to amble will render the tramel more easy to him, and he will find the motion without stumbling, or being frightened. *See the article TRAMMEL. Bradley's Dict. Rust.*

AMEL-CORN, the same with spelt. *See SPELT.*

AMERICAN GRASS. *See AGROSTIS CORNUCOPRIA.*

ANBURY, a kind of wen, or spongy wart growing on any part of a horse's body. *See the article WEN.*

ANGORA goat. *See the article GOAT.*

ANJOU cabbage-shrub, an excellent vegetable both for the kitchen and the food of cattle, cultivated with great success in several provinces of France; and that ingenious husbandman, the marquis of Turbilly lately sent a parcel of the seeds to our society for the encouragement of arts, who very readily distributed them to such gentlemen as applied to them for that purpose, in order to their being cultivated here: so that there is reason to hope, that this useful plant will soon become common in England. The following instructions are given by the marquis de Turbilly, for cultivating the Anjou cabbage.

"The great Anjou cabbage is one of the most useful leguminous plants for country people. It will grow in almost any soil, not excepting even the most indifferent, provided it be sufficiently dunged. It is but little known about Paris, and in many other places, where it might be cultivated to great advantage.

"The seeds of this cabbage are commonly sown in June, in a quarter of good mould, in the kitchen garden, and watered from time to time in case of drought. The plants will rise pretty speedily, and should be thinned soon after, wherever they stand too thick. The next care is to keep them free from weeds whilst they continue, by hoeing the ground between them. About the first of November they should be transplanted into the field where they are to remain. They should be planted there in trenchers dug with a spade, pretty deep, that is, they should be buried almost up to the leaves. The distance between them should be two feet, or two feet and a half every way, according to the goodness of the soil. Particular care should be taken never to plant them with a dibble, as gardeners plant other sorts of cabbages. A layer of dung should be spread along the bottom of the trench, and the roots of the transplanted cabbages covered therewith. The mould taken out should then be returned back upon the dung; and as the trench will then no longer hold it all, there will remain a ridge between each row of cabbages.

"Towards the middle of May ensuing, the ground should be well stirred between the plants, with a spade, or some other proper instrument, and its whole surface laid quite level. After this, nothing more remains to be done, except pulling up the weeds, from time to time, as they appear.

"Many husbandmen sow the seeds of these cabbages with those of hemp; and though this may not be so sure as the former, it often succeeds very well, especially in wet years. When the hemp is pulled up, a multitude of little cabbages are seen, and which having then a free air, grow apace. They are transplanted about the first of November in the manner before directed, and are preferred to those of the kitchen garden, because they are not so apt to run up to seed the next spring; an accident which sometimes happens to a few of these cabbages, in certain years; and it then becomes necessary to replace them by others which have not run up, and which are reserved for this purpose in a separate spot of ground.

"Several farmers use a plough to cut the trench for transplanting these cabbages; but then they do not remove them till the spring, leaving them, in the mean time, in the place where they were sown. They afterwards give the earth a stirring with the spade, and lay it smooth towards the end of May, in the manner before directed. Whole fields of these cabbages may be seen on many farms in Anjou and Poitou, and which prove a very useful resource.

"In the month of June, such of these cabbages as are already large, and do not turn in their leaves for cabbaging, but still continue green, begin to be fit for use, and soon arrive at their full perfection, which they retain till the next spring, when they begin to run up, and afterwards

blossom. Their seeds ripen towards the end of July, and what is intended for sowing should then be gathered.

"In Anjou, when these cabbages are entirely run up, they generally grow to the height of seven or eight feet: sometimes they reach to eight feet and a half, or nine feet; nay, some have even been seen of a greater height.

"From the month of June, when these cabbages begin to be fit for use, their leaves are gathered from time to time, and they shoot out again. They are large, excellent food, and so tender that they are dressed with a moment's boiling. They never occasion any flatulencies or uneasiness in the stomach; and are also very good food for cattle, which eat them greedily. They likewise greatly increase the milk of cows.

"Such are the properties of this kind of cabbage, greatly esteemed in Anjou, Poitou, Brittany, Le Maine, and some other neighbouring provinces. In Anjou, farmers are bound by their leases to plant yearly a certain number of these cabbages, and to leave a certain number of them standing when they quit their farms.

"This cabbage forms a kind of shrub, the great utility of which may be gathered from this, that its leaves afford nourishment to men and cattle; and its stalk, which is about the thickness of one's wrist, is used, when dry, for fuel.

"It sometimes happens in extremely severe winters, that some of these cabbages are frozen; and this, in the above provinces, is considered as a very great loss; but that accident is rare, because this kind of cabbage resists frosts better than most others.

"The ground where these cabbages are planted should be fenced in very carefully by hedges or ditches, to preserve it from the depredations of cattle, which are extremely fond of them. With this precaution I have made several plantations of them, near the houses erected in the midst of the heaths and commons I have broken up and improved; and they have succeeded very well, though the soil is but indifferent in many places.

"I have, near my house in Anjou, two well enclosed fields, destined for this sort of plantation. They are planted alternately every year with young cabbages. When these are pulled up, after they have seeded in the second year, at the time already mentioned, the ground where they stood is dug up, and sowed with pease or beans, the crop of which being taken off before the first of November, makes room for planting new cabbages at the proper season. The soil is loosened and enriched by the pease and beans, and by this means the land is never rested; nor is it ever exhausted, because it is dunged whenever the cabbages are planted.

"These cabbages are of such excellent service to me, that I have often wondered at their not being cultivated in all the different countries of Europe. I believe they would succeed every where, and I advise all husbandmen to make plantations of them.

"I wish that this short memoir, founded on my own experience, may contribute to extend the culture of this useful plant."

ANNO TA is an ingredient made use of to colour cheese, a vegetable production brought from America, and brought to England originally for the use of dyers. It is the produce of *Bixa Orellana* of Linnæus. It is described by Miller in its plant and propagation. It is a tall shrub somewhat in resemblance to the lilac. The colouring material is the pulp of the fruit; among which the seeds are bedded, in the same manner as those of the rose in the pulp of the hip. It has been tried as a colouring of cheese in its genuine state, but without success. The preparation in use is made by the druggist, and sold in the shops. In colour and texture it is not unlike well-burnt red brick. The hardest and closest is esteemed the best. The method of using it is thus: a piece of the preparation is rubbed against a hard smooth even-faced pebble or other stone, the pieces being previously wetted with milk to forward the levigation, and to collect the particles as they are loosened. For this purpose a dish of milk is generally placed upon the cheese-ladder; and as the stone becomes loaded with levigated matter the pieces are dipped in the milk from time to time; until the milk in the dish appear (from daily practice) to be sufficiently coloured.

The stone and the "colouring" being washed clean in the milk, it is stirred briskly about in the dish; and, having stood a few minutes for the unsuspended particles of colouring to settle, is returned into the cheese-cowl; pouring it off

off gently, so as to leave any sediment which may have fallen down, in the bottom of the dish: The grounds are then rubbed with the finger on the bottom of the dish, and fresh milk added; until all the finer particles be *suspended*: and in this the skill in colouring principally consists. If any fragments have broken off in the operation, they remain at the bottom of the dish: hence the superiority of a hard closely textured material, which will not break off or crumble in rubbing.

The price of annots is about ten pence an ounce; which will colour about twenty thin cheeses (10 to 12 pounds each). The colouring therefore costs about a halfpenny a cheese.

ANNUAL plants, such as continue one year only: or such as spring up, ripen their seed, and perish in that space of time. Thus wheat, barley, oats, beans, pease, &c. are annual plants.

ANNUAL meadow-grass, called in some parts of England, Suffolk-grass, a species of very beautiful grass, making the finest turfs, and seems particularly well adapted to dairy farms. See Plate I. fig. 1. which represents this grass in its perfection.

"I have, says Mr. Stillingfleet, seen whole fields of it in High-Suffolk, without any mixture of other grasses, and as some of the best salt butter we have in London comes from that country, it is most likely to be the best grass for the dairy." He adds, that he observed, upon Malvern-hill, a walk made there for the convenience of the water drinkers, which was, in many places, covered over with this grass in less than a year, though he could not find a single plant of it besides in any other part of the hill. This was doubtless owing to the frequent treading which has the greatest tendency to make this grass flourish; and therefore it is very evident, that rolling must be very serviceable to it. As the flowers and stems of this plant do not grow brown so soon as those of other grasses, nor cover the radical leaves so much, because they are considerably shorter, this affords a more pleasing turf than any other grass." *Stillingfleet's Miscel. Tracts.*

Mr. Ray observes of the common meadow grass, that it is a slender and succulent plant, very agreeable to cattle, and a fattener of them; that it delights in a rich soil; and that it is not injured by being trodden under foot, and therefore is commonly found along the sides of paths and roads. It spindles and ears in the spring, and continues to shoot during the whole summer. *Ray's History of Plants.*

As plenty of the seeds of this grass might be very easily procured from Suffolk, it might be propagated and cultivated in all parts of England, where the soil and situation are adapted to its growth.

It is indeed amazing, that amidst the great variety of grasses that grow naturally in England, that so few farmers have had any thoughts about improving their meadows and pastures; they seem to take every thing upon trust, imagining, perhaps, that the grass they find growing naturally in their grounds, is much better, and more adapted to the nature of the soil, than any other they could sow, or adopt in its stead.

But this is surely a very narrow way of thinking; and should it be encouraged, would soon put a stop to all improvements in husbandry. We have been too long influenced by custom: it is time for us to shake off our fetters, and rouse ourselves from the deep lethargy which has prevented us from perceiving, or at least from removing the disadvantages of the old husbandry, which in many respects is highly disadvantageous both to the farmer and his country.

ANTICOR, a disease among horses, consisting of a malignant swelling in the breast; which extends sometimes to the very sheath under the belly; and is attended with a fever, great depression and weakness, and a total want of appetite.

The cure should be first attempted by large and repeated bleedings, to abate the inflammation; emollient clysters should be injected twice or thrice a day, with an ounce of sal prunella in each. The swelling should be bathed with marshmallow ointment, and an opening poultice, with onions boiled in it, should be daily applied over it. If by this method continued four or five days, the inflammation in the throat and gullet be removed, the attention should more particularly turn to encourage the swelling on the breast, and bring it, if possible, to matter: let the poultice therefore be continued, and give the horse two ounces of Venice treacle, dissolved in a pint of beer, every night.

When the swelling is grown soft, it must be opened with a knife, and dressed with turpentine digestive; the danger being then over.

But should it be found impracticable to bring the swelling to matter, and the swelling upwards should increase so as to endanger suffocation, authors have advised to pierce the humour with a hot pointed cautery, and dress part with the turpentine digestive; sharpened with a small quantity of Spanish flies and euphorbium in powder; in order to stimulate and promote a greater discharge; at the same time fomenting and bathing the adjacent parts with ointment of marshmallows.

M. Gueriniere, as well as Soleyfel, have advised opening the skin, when the tumour cannot be brought to matter, in order to introduce a piece of black helebore-root steeped in vinegar; and to confine it there for twenty-four hours; this also is intended as a stimulant, and is said to answer the intention, by occasioning sometimes a swelling as big as a man's head. *Bartlett's Farriery.*

ANTS, or *pismires*; are injurious both to pasture lands and gardens; in the former by throwing up hills, and in the latter, by feeding on the fruit, &c.

The method of keeping them from trees is by encompassing the stem with a circle or roll of wool, newly plucked from the sheep's belly, four fingers in breadth; or by laying saw-dust round the tree. The same will be effected when you anoint the tree with tar; but as tar is prejudicial to trees, human ordure, will, perhaps, do better; because if any of it be put into their hills, it will kill them. *Mortimer's Husbandry.*

ANT-hills, the habitations of the ants, consisting of little eminences, composed of small particles of sand, lightly and artfully laid together.

These hills, or habitations of the ants, though very convenient for themselves and their own societies, are very destructive to the farmer, depriving him of as much land as these hills cover; which may be often computed at a tenth part, or more of his valuable grass lands. Nay, in some places, where negligence has suffered them to multiply, almost half of it has been rendered useless: the hills standing as thick together as grass-cocks in hay time: and what is most surprising, this indolence is defended by affirming, that the area or superficies of their land is thereby increased: whereas it is well known, by the industrious, that very little or no grass ever grows thereon; and therefore if the surface be increased, the produce is proportionably decreased. See the article MOLE-HILL.

It has been a custom in many places at the beginning of winter, and often when the weather was not very cold, to dig up the ant-hills, three or four inches below the surface of the ground; and then to cut them in pieces, and scatter the fragments about: but this only disseminates the insects instead of destroying them; they can hide themselves among the roots of the grass for the present; and then collect themselves together again upon any little eminence, of which there are great numbers ready for their purpose, viz. the circular ridges round the hollows, where the hills stood, as is very soon visible to a curious observer. A much better method seems therefore to be pointed out by a writer in the *Museum Rusticum*, vol. vi. namely, to cut off the hills entire, and even with the surface; and to let them lie whole at a little distance, with their bottom upwards: by this means the ants, which are known to be very tenacious of their nests, will continue in their habitations, while the rains, by running into their holes of communication, assisted afterwards by the frosts, which will now sooner penetrate to their dwellings, will destroy them. Perhaps a little soot sown on the places, and washed in with the rains, would have a better effect. The hills when rendered mellow by the frosts, may be broken and dispersed about the land. This method of cutting the hills even with the surface, has one advantage; it leaves the pasture-land even and fit for mowing; and at the same time the little eminences being taken away, the insects are exposed to the wet, which is disagreeable to them.

In wet weather these insects accumulate cavernous heaps of sandy particles among the grass, called by the labourers sprout-hills; which quickly take off the edge of a scythe. These hills, which are very light and compressible, the above writer assures us from experience, may be readily stamped down, by the feet of the hay-makers, and the insects, together with their eggs and earth, easily pounded to a mortar. This should be repeated a second, and perhaps a third time, after the itinerant foragers have returned from their

their quest of food, and have begun to raise new structures near the old demolished habitations.

Mr. Marshall, in his *Rural Economy of Norfolk*, says, that a tenant had leave to cut and burn ant-hills off a dole belonging to his farm upon a common. His motive was his improvement of his farm by the ashes; and his pretext the improvement of the common: both of which he obtained. He levelled the ground and raked in grass-seeds. His process was to cut them up with a heart-shaped sharp spade or shovel, in irregular lumps of ten to fifteen inches diameter, and from two to five or six inches thick. These he turned the grass downward, until the mould-side was thoroughly dry, and then he set up the grass outward until they were dry enough to burn. He kindled the fire with brush-wood and kept it smothering, by laying the sods or lumps on gradually, as the fire broke out, until ten or fifteen or twenty load of ashes were raised in one heap, which the workmen agreed to complete the process for a shilling each load of ashes. Besides the destruction of the ants, this is a cheap way of raising manure; and no man, having such an opportunity in his power, ought to neglect it. On some soils ashes are found in themselves an excellent manure; and, perhaps generally, ashes raised in this way would be found highly advantageous as bottoming for farm-yards and dunghills.

Mr. Young, in his sixteenth volume of the *Annals of Agriculture*, recommends, as a singular experiment, the rolling down ant-hills, instead of cutting them; says he rode over a large pasture which he should not have known had ever been infested with these hills, if he had not been assured that it was once covered with them. No other method was used but repeated rollings, with a very heavy roller.

APHERNOUSLI, or *arkenoufli*, a species of pine, or pinafter, growing wild on the Alps, where one would think it impossible that any tree could vegetate and prosper; and therefore would probably thrive to great advantage on our bleak, barren, rocky, mountainous tracts of land. See Plate I. fig. 2.

The timber is large, and has many uses, especially within doors, or under cover. The branches resemble those of the pitch-trees, commonly called the spruce fir: but the cones are more round in the middle, being of a purplish colour, shaded with black. The bark of the trunk, or bole of the tree, is not reddish like the bark of the pine, but of a whitish cast, like that of the fir. The husk, or sort of shell, which incloses the kernels, is easily cracked, and the kernels are covered with a brown skin, which peels off; they are about as large as a common pea, triangular like buck-wheat, and white and soft as a blanchéd almond, of an oily agreeable taste, but leaving in the mouth that small degree of asperity, which is peculiar to wild fruits, and is not unpleasing. These kernels make a part sometimes in a Swiss desert; they supply the place of mushroom-buttons in ragouts; and are also recommended in consumptive cases, on account of their balsamic oil.

Wainscoting, flooring, and other joiner's work, made with the planks of apherousli, are of a finer grain, and more beautifully variegated than deal, and the smell of the wood is more agreeable. From this tree is extracted a white odoriferous resin.

The apherousli is of a healthy, vigorous nature, and will bear removing when it is young, even in dry warm weather. The wood makes excellent firing in stoves, ovens, and kilns; but is dangerous to be used on the hearth or in grates, being apt to splinter and fly to a considerable distance.

This tree is the *pinus cembra* of Matthioli and Linnæus, the *pinus foliis quinis* in Haller, the *larix semper-virens* in the German Ephemeris, the *libanus carpathius* of some writers, and the *pina cinque feucilles*, N° 20. in Du Hamel. It grows in great abundance on the most mountainous and coldest parts of the Briançonnois, where it is called by the natives *alviez*. It bears some resemblance to the white Canada pine, which is better known in England by the name of Weymouth-pine. *Essays on Husbandry*.

APIARY, a bee-garden, or place where bees are kept. See the article BEES.

APOPLEXY, or, as the farriers generally call it, the *staggers*, a disease to which the horse is subject, and by which the creature drops down suddenly without sense or motion, except a working of his flanks, proceeding from the motion of the heart and lungs, which never cease while any spark of life remains.

The previous symptoms are drowsiness, watery moist eyes,

somewhat full and inflamed, a disposition to reel, feebleness, a bad appetite, and almost continual hanging of the head, or resting it in his manger, sometimes with little or no fever, and scarce any alteration in the dung or urine. When the apoplexy proceeds from water collected in the sinuses and ventricles of the brain, the horse has generally, besides all the foregoing symptoms, a disposition to rear up, and is apt to fall back, when any one goes to handle him about his head. The reason of his falling backwards seems to be obvious, because when the head is raised with his mouth upwards, the water in the ventricles causes a weight upon the cerebellum, or part lying under the brain, and origin of the nerves, so as to deprive the creature of sense and motion at once: this does not, however, prove suddenly mortal. Young horses are most subject to it, and, with proper helps, and good usage, sometimes get over it; but when the apoplexy proceeds from wounds or blows on the head, or from any other cause producing ruptures in the blood-vessels, or from matter collected in the brain, or its membranes; or if any part of the brain or its membranes be indurated, or grown callous, by long continuance, the horse will not only have most of the symptoms already described, but will be frantic by fits, especially after his feeds, so as to start and fly into motion at every thing that comes near him. These cases are extremely dangerous, and seldom admit of a perfect recovery. But when horses fall down suddenly and work violently at their flank, without any ability to rise, even after plentiful bleeding, such horses seldom recover.

All that can be done in such cases is to strike the veins in several places at once, to raise up the horse's head and shoulders, propping them with plenty of straw; and if he survive the fit, to cut several rowels; though in case of ruptured vessels, or if any kind of extraneous matter be lodged in the brain, or its membranes, all these helps will be of little service.

But if the apoplectic fits happen to be only the effect of a plethora, or fulness of blood, from high feeding, and want of sufficient exercise; or if it be the effect of a sily blood, which is often the case of many young horses, that have been fed for sale, or from catching cold while the blood is in this state, the cure will not be attended with any great difficulty, notwithstanding a horse, in these circumstances, may reel and stagger, and sometimes fall down suddenly.

First of all bleed plentifully, and keep the horse for some time to an opening diet of scalded bran, and sometimes scalded barley, lessening the quantity of his hay. After two days repeat the bleeding, but in a smaller degree. If the horse has a cold, it will be proper to give him pectoral drinks, proper for that disorder. See COLD.

But if no symptom of a cold appears it will be necessary, after bleeding and a spare diet, to give him two or three purges, not only to remove the plethora or fulness, but attenuate and thin his blood, for which the following is recommended.

"Take of the finest soccotrine aloes, an ounce and a quarter; fresh jalap, two drams; salt of tartar, three drams; native cinnabar, or the cinnabar of antimony half an ounce; make it into a ball with a sufficient quantity of syrup of roses or marshmallows; adding twenty or thirty drops of chemical oil of aniseeds, making the whole into a ball, rolling it in liquorice-powder."

The purge may be made stronger or weaker by increasing or diminishing the jalap. Let this be repeated two or three times, and the horse will probably recover, without a relapse. Powder of antimony, or its preparations, as the liver, the *cræcus metallorum*, its cinnabar, or the native cinnabar, mixed with equal parts of gum guaiacum, may be also given in ounce doses, for three or four weeks to mend his blood, and take off its siness. Nor should exercise, as soon as the horse is able to bear it, be omitted.

When a horse drops down suddenly with hard riding, or violent driving, it in many respects resembles an apoplexy, and all the organs of the head are affected as in an apoplexy; but as this proceeds only from the extraordinary rarefaction of the blood, and its rapid motion, whereby the small vessels of the brain, heart, and lungs, are so extremely distended as to cause an universal pressure on the origin of the nerves; the horse by this means loses all sense and motion, and generally falls suddenly, especially upon any sudden stop; because when the bodily motion ceases, the circulation of the blood in the veins is not accelerated in proportion to its influx from the arteries, which soon produces a suffocation and

Borer.

and a falling down, without sense or motion: Instances of this kind are not uncommon, especially in very hot weather, when the external heat adds greatly to the blood's motion and rarefaction. But as we suppose, in this case, little or no fault in the blood, except, perhaps, a plethora, or weakness of the vessels, the quickest and readiest remedy is bleeding; and unless the horse dies with the violence of the fall, which sometimes happens, or by bursting the small vessels of the brain or lungs, or happens through polipuses in the heart or principal veins, he will soon rise of himself, or without much help, and may be preserved from such accidents for the future, by better usage. *Gibson on the Diseases of Horses.*

APPETITE, a certain painful or uneasy sensation, always accompanied with a desire to eat or drink.

Horses, more than most other creatures, are subject to diseases of the stomach, particularly to a want of appetite, and a vitiated, or voracious appetite.

Want of APPETITE is when a horse feeds poorly, and is apt to mangle his hay, or leave it in the rack, and at the same time gathers little flesh, and his dung habitually soft, and of a pale colour.

These are evident signs of a relaxed constitution, wherein the weakness of the stomach and guts may have a very great share. This habitual weakness may be either natural and hereditary, or may be caused by some previous ill management; such as too much scalded bran, or too much hot meat of any kind, which relaxes the tone of the stomach or guts, and in the end produces a weak digestion, and consequently a loss of appetite.

The best method to harden and recover such horses, is to give them gentle exercise in the open air, especially in dry weather; never to load their stomachs with large feeds, and to keep them as much as possible to a dry diet, indulging them now and then with a handful of beans among their oats; but in case the horse grows weak, and requires the help of physic, a few laxative purges like the following should be given:

"Take soccotrine aloes, six drams; rhubarb in fine powder, two drams; saffron dried and powdered, one dram: make it into a stiff ball, with a sufficient quantity of syrup of roses, and add two drams of the elixir proprietatis, prepared with oil of sulphur by the bell."

This purge will work very gently, and bring the horse to a better appetite, and strengthen his digestion. It may be repeated once a week, or once in ten days: and, after the operation of each purge,

"Take a large handful of the raspings or shavings of guaiacum, pomegranate bark, and balauftines bruised, of each an ounce; galangals and liquorice root sliced, of each half an ounce: let these be boiled in six quarts of smiths' forge-water, to three pints; and while it is warm, infuse in the decoction two drams of saffron, and half an ounce of diascordium."

Let this be divided into two drinks, and give one after the purge has done working, and the other after two days intermission; in cold weather the drinks should be warmed before they are administered: the same may be complied with after the last purge, and repeated as often as may be necessary, continuing to give the horse constant exercise in the open free air; and this will be the likeliest method to strengthen such horses as are of weak relaxed constitutions.

But where such a habit is contracted by too much feeding, especially on hot scalded diet, which is often the case of young horses kept up for sale, the best way is to bleed and purge such horses, and at the same time to rowel them in the belly; for this sort of feeding easily occasions horses to be lax, that have no natural disposition to it; for when they grow suddenly fat by such management, the secretions from the guts become greasy, which always causes weakness and relaxation in them, and often forms a proper nidus for the breeding of vermin; all which may be easily remedied by purging in the first place, and afterwards by proper exercise, and a clean diet.

As for those horses that are of a hot fiery disposition, and lose their appetites by their heat and fretting, it is a case that cannot easily be remedied, because of the natural inflammatory disposition of their blood; the only method is to keep them to a cool diet while they are young, and, in country places, to let them run abroad, especially where they have stables and warm ranges, to keep them from the inclemency of the weather in winter; for these sort of horses are always tender, being, for the most part, extremely thin skinned, and their blood of a thin texture, and easily put in

motion. For the same reason, the best way, in summer, is to bring them up in the day time, and only let them run abroad in the night, they being more hunted with the flies than any other, which keeps them continually upon the fret, and hinders them from thriving. When such horses live till they are full aged, their heat and fieriness often abates, so that they grow more useful; but while they are young, they are more subject to inward imposthumations than horses of a cooler temperament; and these often kill them suddenly, or bring them into lingering consumptive maladies, which in some measure may be prevented by the above method. *Gibson on the Diseases of Horses.*

Vitiated, or Voracious APPETITE, is that where the animal is always craving for meat. See FOUL-FEEDING.

APPLES. Nature has furnished us with only one sort of this species of fruit, viz. the crab, common in woods and hedges. Linnæus, who knew all nature, takes no notice of the apple, as he considered it as no other than cultivated varieties of the pyrus malus, or crab; but we require not the assistance of botanic knowledge to convince us, that the numerous sorts of fruit, which are cultivated by orchardmen and gardeners, are not natural species. Nature propagates and continues its own species by seed. But the seeds of a given species, or rather variety of apples, will not produce apples of the same kind, but a number of different kinds, most of them, probably, resembling the wood-crab, rather than the apple which produced them, let its richness and flavour be what they may. Indeed repeatedly sowing the seeds of the seedling in common soil, the common crab would, no doubt, be produced.

The fact seems to be, that fruit is not naturally a permanent specific character; even the native wild crab is subject to infinite variety in colour, shape, and flavour; but by art the qualities of fruit may be identically preserved.

The business, therefore, of the improvers of fruit is to catch at superior accidental varieties, and having raised them by cultivation, to the highest degree of perfection they are capable of, to preserve them in that state by artificial propagation.

The law of Nature, however, though it suffers man to improve the fruits which are given us, appears to have set bounds to his art; and to have numbered the years of his creations. Artificial propagation cannot preserve the varieties in perpetuity. A time arrives, when they can be no longer propagated with success. All the old fruits, which raised the fame of the liquors of this country, are now lost; or are so far on the decline, as to be deemed irrecoverable.

The redstreak is given up; the celebrated fire apple is going off; and the squash pear, which has probably furnished this country with more champaign than was ever imported into it, can no longer be got to flourish: the stocks canker and are unproductive. In Yorkshire, similar circumstances have taken place: several old fruits, which were productive within recollection, are lost: the stocks cankered and the trees would no longer come to bear.

The duration of varieties may, however, depend much upon management. For although Nature wills that the same wood, or the same set of sap-vessels (for the wood which is produced by grafting is, in reality, no more than a protrusion of the graft,—an extension of the original stock) shall, in time, lose its fecundity; yet, it is probable, that the same art which establishes a variety, may shorten or prolong its duration. Much may depend upon the stock, and much upon the health of the tree, and the age of the wood, from which the graft is taken. Or, perhaps, the canker (which seems to be the natural destroyer of varieties) may be checked. But of these in their places.

The popular idea among orchardmen is, that the decline of the old fruits is owing to a want of fresh grafts from abroad—from "Normandy"—under a notion, that the highest-flavoured apples grow there, in a state of Nature, as the crab in this island.

That the first fruits of our ancestors were fetched from the continent is highly probable. But it is equally probable, that the sorts which were originally imported, have long ago been lost; and that the numerous varieties, we are at present possessed of, were raised from the seed, in this country. Miller, whose extensive practice and connexions enabled him to be an adequate judge of this subject, speaks of them as such. After enumerating some French apples, he says,—"the sorts, which are above-mentioned, are what have been introduced from France; but there are not above two or three of them which are much esteemed in England; viz. the French rennette, the rennette-grise, and the violet

violet apple; the other being early fruit, which do not keep long and their flesh is generally mealy, so that they do not deserve to be propagated; as we have many better fruits in England, which I shall next mention:" and in mentioning the golden pippin, one of the first apples we know, either for the table or the cider press, he says "the golden pippin is a fruit peculiar to England. There are few countries abroad where this succeeds well."

The fire apple is generally understood to be a "kernel fruit:" and the Hagloe crab, whose fame as a cider fruit is little inferior to that of the fire, is still traceable to the parent stock. The original tree is still in being.

It is probable, however, that many of our present fruits have not been produced from our own native crab; but from the apples which were originally imported. Nevertheless, it is more than probable, that some of the higher-flavoured, firmer fruits, as the golden pippin, have been raised, by cultivation, from the native species. The process is simple and easy: and a young man of ingenuity and enterprise, and in a proper situation, might be less rationally employed, than in improving this species of his country's produce.

Select, among the native species, individuals of the highest flavour. Sow the seeds in a highly enriched seed-bed, in the manner which will be described. Select, from among the seedlings, the plants whose wood and leaves wear the most apple-like appearance. Transplant these, into a rich deep soil, in a genial situation, and at distances which will be mentioned; letting them remain in this nursery until they begin to bear.

With the seeds of the fairest, richest, and best-flavoured fruit, repeat this process. And, at the same time, or in due season, engraft the wood which produced this fruit, on that of the richest, sweetest, best-flavoured apple: repeating this operation; and transferring the subject, under improvement, from one tree and sort to another, as richness, flavour, or firmness may require. Continuing this double mode of improvement, until the desired fruit be obtained.

There has, no doubt, been a period, when the improvement of the apple and the pear was attended to in this country. And should not the same spirit of improvement revive, it is probable, that the country will, in a course of years, be left destitute of the valuable kinds of these two species of fruit: which, though they may in some degree be deemed objects of luxury, long custom seems to have ranked among the necessities of life.

Having thus endeavoured to convey a general idea of the nature and propagation of varieties, it will be proper to enumerate some of the most celebrated of those which are now in cultivation, in these counties:—to describe, or even enumerate, all the present varieties of orchard fruit would be impossible. They are without number. In Herefordshire, more particularly, a very considerable proportion of the fruit which is grown is "kernel fruit;" produced from trees that have been raised from the seed; and which have never been grafted. Consequently each tree is a separate variety; bearing the name, perhaps, of its planter, or of the "ground" it grows in.

There are, nevertheless, numbers which are universally known; and some of them sufficiently celebrated to be entitled to notice.

Of apples, the fire stands first in estimation. The fruit of this variety is somewhat below the middle size. The form rather flat. The colour a pale yellowish white, with sometimes a faint blush on one side. The flesh tolerably firm. The flavour, when fully ripe, fine. It is deemed, by most people, a tolerably good eating apple. The cider, which is produced from it, in a soil that is adapted to it, is rich, highly flavoured, and of a good body:—its price frequently fourfold that of common sale cider. The thin limestone soils on the margin of the forest of Dean, are said to produce the richest fire cider. The tree which bears this apple is of a singular growth:—remarkably "beefom headed:"—throwing out numerous, straight, luxuriant, upward shoots, from the crown; taking the form of a willow pollard; running much to wood; and, in deep soils, growing to a great size before it become fruitful.

There is an apple called the red fire; but it has no peculiar affinity with the true fire. In Herefordshire, about Marcle, I met with a "yellow fire"—and on the forest there is the "kernel fire:"—both of them probably kernel fruits, which, bearing some likeness of the true fire, have had its name improperly given them.

The Hagloe crab is, at present, next in esteem. It has

already been mentioned, that this variety is traceable to the original seedling. It was produced, about seventy years ago, in a nursery among other stocks raised from the seed, by Mr. Bellamy of Hagloe, in Gloucestershire, grandfather of the present Mr. Bellamy, near Ross in Herefordshire; who draws from it (that is, from trees grafted with scions from this parent stock) a liquor, which, for richness, flavour, and price on the spot, exceeds, perhaps, every other fruit liquor, which nature and art have produced. He has been offered sixty guineas for a hoghead (about 110 gallons) of this liquor. He has likewise been offered bottle for bottle of wine or spirituous liquors, the best to be produced; and this without freight, duty, or even a mile of carriage to enhance its original price.

This fruit, while growing, is nearly white; when fully ripe it has a yellowish cast; sometimes freckled with red on one side, like the common white crab. The size about that of the fire apple; but the form more oblong. The flesh remarkably soft and woolly, but not dry; being furnished with a sheer, but, when fully ripe, sweet juice; which, however, is much smaller in proportion to the quantity of fibrous matter, than that of most other apples. The flavour, when ripe, resembles that of the cashew apple of the West-Indies; and, what is remarkable, the texture of the flesh is not unlike to the pulp of that fruit. The cider, notwithstanding the sheerness of the juice, is, when properly manufactured, singularly rich; and notwithstanding the faint smell of the apple, is highly flavoured: and, what is equally remarkable, the liquor is of the highest colour, notwithstanding the paleness of the fruit.

The golden pippin is in high estimation as a cider apple; and may rank as the third of this district. It is more generally known than the Hagloe crab, and, at public market, its liquor, I believe, is generally next in price to that of the fire apple.

The old red-streak is yet in being. A few old trees are still remaining. The fruit small, roundish, of a pale yellow ground, with numerous faint red-streaks. The flesh firm, full of juice, and, when ripe, finely flavoured; a palatable eating apple. The cider, at present, is not, I believe, in particular estimation: little if any genuine redstreak cider is now made. It never was, I believe, equal to that of either of the preceding apples. The tree of this apple is of a singularly awkward growth; Crooked, reclining, ragged and unsightly.

The woodcock is another favourite old cider fruit. But is now going off: many old trees, however, are still left in the district. The fruit is much larger than any of the preceding sorts: above the middle size. The form somewhat oblong; with a long stalk, set on in a peculiar manner; feigned to resemble the woodcock's beak (hence the name). The colour that of the redstreak, with the addition of some dark blood-red streaks on one side. The flesh remarkably fine; equally fit for culinary purposes and for cider. The tree large and strongly featured; forming large boughs in the pear-tree manner.

Other favourite cider apples, at present, are:

The must:—an old favourite fruit, of which three sorts are enumerated.

The pauson:—a middle-sized, green apple.

The royal wilding:—a large white apple.

The dymmock red:—middle-sized, red.

The coccagee: above the middle size: greenish white, with an orange blush:—well fleshed, and highly flavoured.

Russets, of various kinds, are in good esteem: particularly the Longney russet.

Bromley, foxwhelp, red crab, queening,—all of them large red apples,—are in good estimation for cider. *Marshall's Rural Economy of Gloucestershire.*

Mr. Young in his *Annals of Agriculture*, vol. vii. has a letter from Mr. Gullet of Exeter, which recommends the following method to effectually destroy the insect that prevents the blossoms of apples and other fruit trees from producing fruit. These insects are deposited in their egg-state by a fly, in the bud of the apple, or blossom, at its first opening, and they soon become a maggot, which exhausts the nourishment of the blossom, which with the slightest touch will fall off. It is strongly recommended to set fire to some heaps of wet straw, weeds, or any other like matter on the windward side of the garden or orchard, viz. if the wind is east, let the fumigation be from that point, so that the smoke from the heaps may blow through the tree for some days. The expence attending will be very trifling, considering the beneficial effects of it, as it will not only destroy the

the insects for the present, but prevent them from depositing their eggs. The heat and ashes will likewise contribute to the fertility of the soil, the sweetness of the pasture, and the growth and vigour of the trees for future bearings.

APRIL, the fourth month of the civil year, consisting of thirty days.

This month is the best month, if the weather be dry, to sow barley and white oats, to destroy weeds, and also to fallow land:

Fell the timber you intend to bark, if the spring be forward: cleanse and rid your coppices, and preserve them from cattle: keep geese and swine out of commons and pastures, and water new planted trees, if the weather prove dry.

Pick up stones on the new sown land: sow hemp and flax.

Cleanse ditches, and get in your manure that lies in the streets or lanes, or lay it in heaps.

Set osiers, willows, and other aquatics, before they are too forward, and also slips of rosemary or lavender.

You may throughout this month sow clover grass, saint-foin, and all French and other grasses, or hays: plant madder, and be selling your winter-fed cattle. *Mortimer's Husbandry.*

AQUATICS, or aquatic plants, such plants and trees as grow in water.

Thus, the willow, osier, water-creffes, brook-limes, &c. are aquatics.

Mr. Marshall, in his Rural Economy of the Midland Counties, says, that he dressed lands with the aquatic manure, (raised two or three years before, out of a fish-pool, and afterwards turned up into a heap of digest), the rest of the piece being manured with yard dung; the quantity of each about eight loads an acre. The two lands dressed with the aquatic manure, were obviously the better crop of turnips. The plants were not more numerous, but they were larger and cleaner-skinned; and what is remarkable, while the crop of the piece in general was full of catlock and chickweed, (which arose since the hoeing) the two lands were, in a manner, entirely free from those weeds.

ARABLE land, such land as is tilled, or cultivated for the production of corn.

ARAIRE, the name of a small plough used in Provence and Languedoc, in France.

It consists of a ground wrift, *a, b*, (Plate I. fig. 3.) from three to four feet long, ending in a point towards *b*. The under part of this wrift, instead of being flat, is formed into a ridge, which extends the whole length of it.

This ground wrift, at the end *a*, terminates in a strong tenon fixed in a large mortise, formed at the extremity *d* of the beam *d e*, and is besides fastened to the beam by two iron uprights *f g*, which have a head at *g*, and going through the beam are keyed at *f*: the distance between the under part of the beam about *f*, and the upper part of the ground wrift towards *g*, is about fifteen inches. Instead of these uprights there is sometimes put a piece of sharpened wood or iron, as represented by the pricked line *h g*, which serves instead of a coulter.

On the upper part of the ground wrift is fixed a large iron share *d h* (fig. 4.) the part *d i*, is received into the same mortise of the extremity *d* (fig. 3.) in which the tenon of the ground wrift is fastened; and the wings of the share *k l* (fig. 4.) rest upon the iron uprights *f g* (fig. 3.)

On the hindmost part of this plough is a single lever *m d* (fig. 3.) which serves for a handle: at the end *d*, where it is bent, it enters, as well as the ground wrift and share, into the great mortise *d*, at the end of the beam; and the whole is secured with wedges. The handle sometimes consists of two pieces lapped one over the other, as at *n*, to lengthen or shorten it, according to the height of the ploughman.

By means of the wedges just mentioned, the angle which the ground wrift forms with the beam, may be altered at pleasure, which makes it plough more or less deep. At the hinder parts of the ground wrifts are two earth boards, fastened at *a*, by a strong wooden pin, which passes through both the boards and the ground wrift.

The beam *d, f, e*, which from eight to ten feet long, has an iron bolt at the end *e*, which enters with great ease into a large mortise made at the extremity *g*, of the piece of wood *q 5 r*, intended to pass between the oxen, and to which their harness is to be fastened. When a single horse is used in the plough, a shaft is substituted instead of the

piece of wood *q 5 r*, and fastened to the end of the beam *e*, by an iron ringlet.

It is evident that this plough goes a greater or less depth, according as the draught is more or less raised. The ploughman, as has been already observed, can alter the angle which the ground wrift forms with the beam, by means of the wedges he drives into the mortise of the beam, which receives both the ground wrift and handle. But these directions not being sufficiently exact, it is necessary that the ploughman should lean on the handle *m*, when it cuts too deep, and raise it when it makes too shallow a furrow: this labour is so constant, that were the plough to work in a strong soil, the ploughman could not support it. The two little earth boards *p p*, turn over to the right and left the earth that has been loosened by the share; but this is not done so regularly as when there is but one earth-board, which throws the earth into the furrows before made, as fast as it comes out of that which the plough is forming: it is however certain, that the ground wrift being ridged, the ploughman always rests it on one side, which occasions the greater part of the earth to be thrown one way.

These ploughs having no coulters, the earth is not cut vertically at all: for neither the piece of sharpened wood, nor the sheath which joins the ground wrift to the beam, and which is placed a little before the small iron bars *f, g*, can be esteemed a coulter. The bar represented by the pricked line *h g*, may serve instead of a coulter, but it must then be made of iron; and in this case the coulter would be very improperly situated, for it should by rights be before the share.

These ploughs are very convenient to use among trees, or in vineyards; they may also serve to stir the ground in the intervals between the rows of saint-foin and lucerne; but then should be rather called cultivators, than ploughs: *Du Hamel's Elements d'Agriculture.*

ARCHIMEDES's screw, a kind of spiral pump, for raising water, so called from Archimedes, its inventor.

It consists of a long cylinder, with a hollow pipe, tube, or groove coiled round, as represented on Plate I. fig. 5. where *A B* shews the cylinder, and *C D* the tube open at each end. It is placed in an oblique position to the horizon, with the lower end in the water to be raised, and the other supported by the pivot below the winch *J K*, by which the tube and cylinder are turned round.

As soon as the screw is immersed in the water, it immediately rises therein by the orifice *C*, to the level of the surface of the water *E F*; and if the point of the spiral tube, which in the beginning of the motion is coincident with the surface of the water, happens not to be on the lower side of the cylinder, the water will, upon the motion of the screw, move on the spiral tube, till it comes to the point which is on the other side, and coincident with the surface of the water; when it is arrived at that point, as suppose at *O*, it cannot afterwards possess any part of the spiral, but that which is upon the lowest part of the cylinder; for it cannot move from *O* towards *H* or *G*, because they are situated higher above the horizon; and since this will constantly be the case, after the water in the spiral has obtained the point *O*, it is plain that it must always be on the under part of the cylinder.

But because the cylinder is in motion, every part of the spiral screw from *O* to *D*, will by degrees succeed to every part thereof from *O* to *D*, as it comes on the lower side; that is, it must ascend on the lower part of the cylinder through all the length of the pipe, till it comes to the orifice at *D*, where it will run out, as having nothing farther to support it.

This engine may be very useful in raising water, foul with sand, &c. as the leathers of pumps will be soon destroyed by these particles. And it was principally this reason that induced the ingenious Mr. Smeaton to erect a machine of this kind in the gardens of her royal highness the princess dowager of Wales, at Kew, where it is worked by horses, and supplies all the ponds, &c. in that extensive garden with water. A machine of this kind, turned by a windmill, might be of great use in draining lands in several parts of England, as it is not subject to be out of order, and might be made to raise a very large quantity of water to a small height. We shall describe several other contrivances for this purpose when we come to treat of draining of lands, there being many very curious and useful engines of this kind deposited in the machine room of the society for the encouragement of arts, &c. See the article DRAINING of LANDS.

ARCHIMEDES's screw, is an engine of great use, for raising water a few feet high. The best way of making it is, not with a hollow pipe coiled round the shaft or axis, which would be liable to many accidents, but by cutting a spiral groove about an inch deep, and the same wide, round the axis, and extending near the whole length of it. Narrow boards of oak are fitted to the groove, and made to join very close to each other sideways. They are then sawed off very even, and to the same height above the shaft, and narrow deal boards, close jointed, nailed upon the tops of the oaken boards, forming a hollow cylinder, which is bound with iron hoops. One end of this cylinder being dipped in the water, the other end is raised the intended height, and by turning the cylinder or barrel round, the water is raised, as before explained. If the barrel was raised perpendicular, the engine would have no effect, for no water would be raised. In general, the higher the upper end of the engine is raised, it discharges the less water, and is the easier worked: the best position is to place it obliquely, so that the barrel makes an angle about 45 degrees from the perpendicular.

Sometimes this engine is made with only a single spiral partition or thread; and sometimes with a double one, which is found to raise more water than the single: but when there are three such parallel threads in the barrel, it does not raise so much water as with two.

This engine is liable to few accidents, and if well constructed, pitched within and without, and kept in a house, or under a dry shed when not in use, will last a long time, with very little repairing.

The barrel may be made a little wider at the upper end than at the lower, that goes in the water, which answers two purposes; one is, that if the water is foul, the mud, sand, and gravel, is not apt to stick by the way in rising, as it might do, if the barrel was a cylinder, equal in diameter throughout its whole length. And by making the barrel a little conical, the iron hoops take the better hold, and draw the joints of the covering boards the closer. These boards may be of deal, for lightness.

The quantity of water that a screw engine will raise, depends upon various circumstances, the number of threads in the barrel, its size, elevation, &c. In general, if an engine of two threads, is 18 feet long in the barrel, is elevated to an angle of 45 degrees, it will throw out all the water that springs up in a surface of from two to three thousand square feet; and will keep a pond, or bottom of a lock or sluice, dry enough for men to stand in and repair it: this, however, is to be understood, where the bottom and sides of the pond is of a pretty close soil: for if the soil is very sandy, gravelly, and porous, the water will force through such a soil too fast, for one such engine to keep the pond dry; the 18 feet long is the largest screw engine commonly made.

The engines of this size are worked with horses, proper wheel-work being fixed to the upper end of the shaft for that purpose. Twelve horses are necessary to turn it, four each time; and sometimes sixteen horses are necessary. There are frequently smaller screw engines made, to be turned by men, with a crank or bent handle, at which four or five men can work at once, and the men changed every four hours: these answer very well where the water to be raised is in smaller quantity. These engines raise the water about four, five, and sometimes six feet high, and throw it over a bank or wall.

ARDERS, fallowings, or plowings of land.

AROMATIC, an epithet applied to such plants, and other bodies, as yield a fine fragrant smell, and have a warm spicy taste.

ARPENT, the French name for an acre. See **ACRE**.

We have already observed, under the article *acre*, that the French arpent contains 100 perches of twenty-two French square feet, which is equal to about one acre and three quarters of a rood English measure. But it may be necessary to add here, that the French have three different arpents, distinguished by the epithets *little*, *middle*, and *great* arpent.

The *little* ARPENT contains 100 perches of eighteen feet and a half square; consequently its superficial measure is 32,400 French feet, equal to 34,603 feet, or three roods, seven perches, and twenty-seven feet English measure.

The *middle* ARPENT consists also of 100 perches, twenty feet square, which makes 40,000 French feet superficial measure; equal to 42,720 feet, or three rood, thirty-six perches, and 149 feet English measure.

The *great* ARPENT, contains ten perches of twenty-two square perches. See the article **ACRE**.

ARTIFICIAL GRASSES, such as are introduced into the field with great care, and cultivated afterwards with much diligence. Such as burnet, clover, lucern, saint-foin, ray-grass, spurry, &c. See the method of cultivating each under its proper article.

ARTIFICIAL PASTURE, such lands as are properly cultivated and sown with the above plants, or any other that yield a great deal of fodder for cattle.

ARTIFICIAL PONDS. See **PONDS**.

ASCARIDES, small worms common in horses, resembling needles, some of them white, and some of an azure colour, with flattish heads. They are often called needle-worms by the farriers.

These worms are very troublesome, and hard to be rooted out, and expose horses to frequent gripes, and other fretting uneasy disorders in the guts. They breed at all times of the year, and often when one brood is destroyed, another succeeds. They are not mortal; but when a horse is pestered with this sort of vermin, though he will go through his business tolerably well, and sometimes feed heartily, yet he always looks lean and jaded; his hair stares as if he was surfeited, and nothing he eats makes him thrive; he often strikes his hind-feet against his belly, which shews where his grievance lies, and is sometimes griped, but without the violent symptoms that attend a cholic or straggary; for he never rolls or tumbles, but only shews uneasiness, and generally lays himself down quietly on his belly for a little while, and then gets up and falls a feeding; but the surest sign is when he voids them with his dung.

These small worms sometimes come away in great numbers with a purge, and some horses get clear of them by purges only; but this does not often happen; for the horses that breed ascarides are above all others, subject to slime and wormy matter. They seem to have their lodgment about the beginning of the small guts, near the stomach, among the concocted aliment or chyle, both from their colour, the symptoms of the gripes, and the sudden fits of sickness these horses are often seized with, which sometimes make them abruptly leave off their food, for a few minutes, and fall greedily to it again as soon as the sick fit is over. They are seldom seen, except when a horse has had a purge given, or when he falls into a natural purging, which those horses are often subject to, and then they come away in very great numbers, with much slime and nastiness. They not only make a horse grow lean, and look surfeited, but in opening his mouth, one may perceive a more than ordinary languid whiteness, and a sickly smell, from the want of those due supplies of blood and nourishment, which give a liveliness to the colour that is always perceivable in sound vigorous horses; so that whatever be the primary cause, these worms seem, in a great measure, to proceed from a vitiated appetite, and a weak digestion, which renders them the more difficult to be removed; for which reason recourse must be first had to mercurials, and after these, to such things as are proper to strengthen the stomach, promote digestion, and give a better tone to the solids.

To a horse, therefore, that is troubled with these small, white, or azure coloured worms, the following method may be observed:

“Take of calomel that has been often sublimed and well prepared, two drams; diapente half an ounce; make it into a ball, with a sufficient quantity of conserve of worm-wood, or of rue, and give it in the morning, keeping the horse from meat and water four hours before, and four hours after taking it.”

The next morning administer the following purge, taking great care to keep the horse from wet, or from any thing that may expose him to catch cold:

“Take Barbadoes, or plantation aloes, one ounce; salt of tartar, two drams; fresh ginger grated, a dram and a half; oil of amber a middling spoonful: make the whole into a ball with flour or liquorice powder.”

This purge may be worked off in the stable with warm water, which is much the safest way when mercurials are given. The calomel ball and purge may be repeated in six or eight days; and again in six or eight days more.

When a horse has gone through a course of these mercurial purges, let the following drink be given two or three times a week, and continued till the horse begins to thrive and look healthful:

“Take rue, camomile flowers, and horehound, of each a handful;

a handful; galangals, bruised in a mortar, three drams; liquorice root, sliced, two drams: boil it in a quart or three pints of forge-water five or six minutes, in a covered vessel, and keep it covered till cold: then strain it through a piece of coarse canvas, and give it in the morning upon an empty stomach." *Gibson on the Diseases of Horses.*

ASH, or ASH-TREE. There are several species of the ash-tree cultivated by curious persons for the sake of variety; but what deserves attention in a work of this kind, is the common ash, called by botanists *fraxinus foliolis ferratis, floribus apetalis*; and is so well known as to need no description.

This tree propagates itself in plenty by the seeds which scatter in the autumn; so that when the seeds happen to fall in places where cattle do not come, there will be plenty of plants come up in the spring; but when any person is desirous of raising a quantity of the trees, the seeds should be sown as soon as they are ripe, and then the plants will come up in the following spring; but if the seeds are kept out of the ground till spring, the plants will not come up till the year after; the ground therefore should be kept clean all the summer where they are sown and not disturbed, lest the seeds should be turned out of the ground, or buried too deep to grow.

When the plants are come up, they must be kept clean from weeds during the summer; and, if they make good progress in the seed-bed, they will be fit to transplant by the following autumn; some ground should, therefore, be prepared to receive them; and as soon as their leaves begin to fall, they should be transplanted. In taking of them up, care should be taken not to break or tear off their roots; to prevent which they should be taken up with a spade, and not drawn up, as is frequently practised; for as many of the plants which rise first from seeds will out-strip the others in their growth, so it is frequently practised, to draw up the largest plants, and leave the former to grow a year longer, before they are transplanted: and to avoid hurting those that are left, the others are drawn out by hand, and thereby many of their roots are torn off, or broken. It is, therefore, much the better way to take all up, little or big, together, and transplant them out, placing the large ones together in rows, and the small ones by themselves. The rows should be three feet asunder, and the plants a foot and a half distance in the rows. In this nursery they should remain two years, by which time they will be strong enough to plant where they are to remain, for the younger they are planted out the larger they will grow; so that where they are designed for use, they should be planted very young; nor should the ground where they are raised be better than that where they are designed to grow. For when plants are raised in good land, and afterwards planted into worse, they very rarely thrive; so that it is much the better method to make the nursery upon a part of the same land, where the trees are designed to be planted, and then a sufficient number of the trees may be left standing upon the ground, and these will outstrip those which are removed, and grow to a larger size.

Where people live in the neighbourhood of ash-trees, they may supply themselves with plenty of self-sown plants, provided cattle are not suffered to graze on the land; for if cattle can come at them, they will eat off the young plants, and not suffer them to grow; but where the seeds fall in hedges, and are protected by bushes, the plants will come up and thrive: in these hedges the trees are frequently permitted to grow till they have destroyed the hedge, for there is scarce any tree so hurtful to all kinds of vegetables as the ash, which robs every plant of its nourishment within the reach of its roots, and should therefore never be suffered to grow in hedge-rows; for they not only kill the hedge, but impoverish corn, or whatever is sown near them. Nor should any ash-trees be permitted to grow near pasture grounds, for if any of the cows eat of the leaves or shoots of the ash, all the butter that is made of their milk will be rank, and of little or no value. In all good dairy countries therefore they never suffer any ash-trees to grow.

If the wood of these trees be rightly managed, it will turn greatly to the advantage of its owner; for by the under-wood, which will be fit to cut every eight or ten years, there will be a continual income more than sufficient to pay the rent of the ground, and all other charges; and still there will be a stock preserved for timber, which in a few years will be worth forty or fifty shillings per acre.

The ash delights in a moist soil, and will thrive even in an undrained moory situation. Even those with osiers will

vie with them. It is a thirsty plant. The ground under an ash is observed to be always comparatively dry; and it is probably from this absorbent nature, that it is so great an enemy to the herbaceous tribe. Turneps, a succulent plant, starves under the ash; and corn never thrives in its neighbourhood. Clover, however, seems to be an exception to this theory. It is nevertheless an undoubted fact, that the ash is a destructive enemy on arable land; and it is highly improper to plant it in hedges. It ought to be planted in waste nooks and corners; or, perhaps, for two reasons, on improveable swamps, and on the springy sides of hills: it would be rendering them useful as sites of plantations; and perhaps by its absorbent nature would render them firm. If the tree gets disbarked, though its appearance should be flourishing on its being felled, the roots will be found decayed, and the stem at the bottom a complete shell; and therefore ought not in point of profit to be suffered to stand. This tree, when it stands amongst the firs and larches, if planted close, will grow too tall and slender, but thrive well when planted alone. They are frequently known to have thrived for at least ninety years, as may be observed by their rings. Of the first ten years as well of the last ten the growth has been slow. Intermediate years the different thickness of the rings in different years were striking, as observed by Mr. Marshall in his Rural Economy of the Midland Counties.

This timber is of excellent use to the wheel-wrights and cart-wrights for ploughs, axle-trees, felines of wheels, dairy-utensils, harrows, oars, blocks for pullies, and many other purposes.

The best season for felling these trees is from November to February; for if it be done either too early in the autumn, or too early in the spring, the timber will be subject to be infested with worms, and other insects: but for lopping of pollards the spring is preferable for all soft wood. *Miller's Gard. Diet.*

ASHES, the earthy particles of combustible substances remaining after they have been burnt.

Mr. Young, in his *Annals of Agriculture*, vol. I. by an experiment, approves of charcoal-ashes in preference to powdered charcoal itself. By another experiment, wood-ashes mixed with mud, he says, are superior to ashes alone, and four times better than mud alone, as a manure. In vol. II. he says wood-ashes appear to be a most powerful manure. In a neighbourhood abounding with vitriolic acid, they more than neutralize that salt; they furnish besides the food of plants. In neutralizing it, the fixed vegetable alkali they contain forms with the acid a vitriolated tartar, which is beneficial.

If the ashes are produced from vegetable bodies, they contain a considerable quantity of fixed salt, blended with the earthy particles; and from these particles the alkaline salts, called pot-ash, pearl-ash, &c. are extracted.

Ashes of all sorts contain in them a very rich fertile salt, and are the best manure of any to lay upon cold lands, especially if kept dry, and the rain doth not wash away their salts. One load of dry ashes will go as far as two not kept so. But as rain-water diminishes their salts, so the moistening them with chamber-lie, or soap-suds, will add greatly to their strength. Two loads of these ashes will manure an acre of land better than six loads of those that are exposed to the rain, and that are not ordered so, which is the common allowance for an acre, though some lands require more, and some less. That the ashes of any sort of vegetables are very advantageous to land, is what is experienced in most places of England, by the improvement that is made by burning of fern, stubble, straw, heath, furze, sedge, bean-stalks, &c. *Mortimer's Husbandry.*

Coal-ASHES, from their calcareous quality, are singularly beneficial to stiff and sour land, for which purpose they are successfully used in the neighbourhood of some great cities, where coal is burnt for fuel. They open clayey grounds, and correct their bad qualities. The gardeners and farmers about London know their value, and make a very profitable use of them, particularly to bring into order those grounds which have been dug for brick-earth. After spreading these ashes upon the clay bottom, they either sow horse-beans, or set the early Spanish, and sometimes the Windsor-bean, in those spots; or else they lay such lands down with rye-grass, which generally succeeds very well. Mr. Bradley blaming the people of Staffordshire, and the counties adjoining, where there are coal-pits, for not improving their heavy grounds around those pits, by manuring them with coal-ashes, which might be easily burnt out of the

the waste coals, says, "that wherever there are plenty of coal-pits, there can be no want of good profitable land." *Bradley's Husbandry*.

Mr. Mortimer agrees entirely with Mr. Bradley, esteeming sea-coal ashes as the best manure of any for cold lands, the most lasting, and the fittest to kill worms. Their sharp and drying quality opens the pores of stiff soils, and discharges a great deal of their viscous quality. Mr. Worlidge looks upon them as an excellent compost when mixed with horse-dung; he adds, that they are a great curer of moss and rushes in moist grounds. *Worlidge's Husbandry*.

Kiln-ASHES, made of straw, furze, &c. are a good manure for almost any kind of soil. In the west of England, farmers sift them over their corn and grass; but this must not be done in windy weather, because they are so very light that they would be easily blown away. They succeed best when laid on just before rain or snow. *Mill's Husbandry*, vol. I.

Peat-ASHES are likewise a very good manure. Mr. Miller is of opinion, that they are greatly bettered by being mixed with lime before they are laid on the land.

Mr. Ellis has rightly observed, that there is a considerable difference between the ashes of lean peat, and those produced by the fatter kind. If barley, says he, be sown so late as the beginning of May, lean peat-ashes in particular may be applied over it, or harrowed in with the grain: but ashes burnt from fat black peat, such as is dug at Newbury, are of so sulphureous a nature, that farmers are afraid to lay them on their barley; nor do they dress their wheat with them till the spring is advanced, and then they are sown over it.

The earth of which this rich manure is made, is taken from a black moorish ground, with a narrow wood scoop, which brings it out like a long brick. These pieces of swampy earth are laid on the ground to dry in the summer; after which they sell for eight shillings a waggon load, for fuel. But when they are to be used for manure, after being dried, they are burnt in heaps of ten, twenty, or thirty loads, laying on more peat upon the outides, as the fire increases within, to keep it from having too much vent.

The great use of these ashes was discovered some years ago; but they soon fell into disrepute, owing to the injudicious management of people, who imprudently laid on too great quantities of them at a time, by which means the corn was burnt. Afterwards they found that six, or at most ten bushels, were sufficient to be sown over an acre of wheat, pease, turneps, clover, rape-seed, or saintfoin, as early as could conveniently be done. But still many are afraid to sow them over barley, lest a dry season should ensue, and burn it up: for these ashes are thought to contain three times as much sulphur as there is in coal-ashes. This is reasonably supposed from their very strong sulphureous smell; their sparkling and jumping when stirred while burning, and their drying up corn by their too great heat. These peat-ashes, as likewise those of wood or coal, will help to keep off the flugs from pease and other grains, by the salt and sulphur contained in them, and conduce very much to their preservation in cold wet seasons. But no danger of over-heating need be feared from the ashes of that peat which grows, as turf, over sandy bottoms, as great quantities do on Leighton heath in Bedfordshire; for these are as much too lean, as the others are too rank. *Ellis's Modern Husbandman*, vol. II.

These ashes are produced from land that is black and crumbly at top, under which lies the peat, to the depth of several feet. They do not burn the peat in the field for ashes, by choice, because the peat is burnt for the ashes when it cannot be dried sufficiently for sale: and then it is burnt in large heaps, with a smothering fire: as is likewise the superficial black earth or moory soil, together with the refuse of the peat: the ashes of these are laid up in round or long heaps, rising at top like the ridge of a house, in order to throw off the rain, and keep them dry, till they are sold. Sometimes they are laid under dry sheds, or in-houses, to save them from wet, which they cannot be wholly protected from by laying them up in ridges exposed to the weather, into which the rain penetrates for some inches deep: and these ashes are never so good manure as those that are kept dry.

Near the surface of the peat-earth here, there is sometimes a bed of whitish earth, called maum, which is a composition of earth and very small shells of the periwinkle kind: this is also burnt to ashes for manure, and the quan-

tity of it in some places is so great, that the ashes are of a whitish colour, and those from the peat or moorish earth are reddish. The white ashes are esteemed to be as good manure as the red: and being a kind of shell-marl, would make good manure without being burnt: as indeed they rarely are thoroughly, though they seldom lay them upon land, till they have passed the fire, or are mixed with the ashes of the peat-earth. The ashes of the peat sold for fuel, and burnt in chimneys, are much stronger manure than the ashes burnt in the field; and if care is taken to keep them dry, are sold for about double the price of the field ashes.

We must not here omit the account which the ingenious Mr. Du Hamel has given of a kind of peat-ashes made in France, as the same kind of earth with that from whence they are burnt may be doubtless found in many parts of England, if farmers would give themselves the trouble to search for it.

This peat is a blackish earth, resembling the soil of some meadows. When burnt it emits a thick, disagreeable sulphureous vapour. A certain degree of moisture helps to make it burn, though even then it wastes but slowly. After it has once taken fire it burns of itself, but without producing any flame. It is of so caustic a nature, that it would strip off the skin of the hands and feet of the men who knead it, if they did not take proper precautions against that inconvenience. Its ashes retain this caustic quality; for the hands of those peasants who strew them are often hurt by it, if the air be at all damp. This earth, in its natural position, runs in veins of different sizes; sometimes seven or eight feet thick, and thirty or forty feet long; and sometimes they extend four or five hundred feet; after which the vein often fails at once, and perhaps is not found again till two or three miles off. These veins generally lie pretty near the surface of the earth, seldom deeper than twelve or fifteen feet.

This earth is found only in marshy places, which must sometimes be drained before it can be come at. It shews itself by a slimy skin over the adjacent waters.

Three pounds of this earth being distilled in a retort, produced fifteen ounces of a bituminous oil, resembling that extracted from pit-coal; and the residuum yielded, when washed, about half a pound of vitriol.

The method of preparing this earth, in order to render it fit for fertilizing land, is as follows: water is thrown over it, and two or three men knead it with their feet, till they bring it to the consistence of a paste, which is then made into cakes seven or eight inches in diameter. These cakes are laid by to dry, though not to such a degree but that there still remains a little moisture in them, that being necessary to facilitate their burning.

Their cakes thus prepared are piled up in the form of a pyramid, with sufficient spaces between them for the fire to penetrate; and under this pyramid, which is built upon a kind of hearth, a little straw and brush-wood is laid to set them on fire. Two or three days after their ashes are spread with a rake, that they may cool. Some veins of this earth yield white ashes, but they are not so good as those of a reddish hue.

From fifty to seventy pounds of these ashes are spread upon each acre of land in April or May; and in about a week's time the blades of corn, or grass, if it be pasture ground, assume a new verdure, and appear surprisingly strong, even in the coldest soils.

Some of these bituminous earths are better than others. Care must be taken to begin to rake out the ashes of each pyramid as soon as the greater part of it is burnt: for they would lose a great deal of their virtue, if left on the fire till all that is inflammable be consumed: nor would the fire go out in less than a fortnight or three weeks, if they were not scraped away as they are formed.

It would be needless to mention, that a greater quantity of the ashes of an inferior quality must be used, than those that are stronger, and consequently better; but it may not be amiss to observe, that, in general, wet lands require more than dry soils. The effects of this manure will be manifest for two or three years. It might be dangerous to renew it every year. *Traite de la Culture de Terres*, tom. V. pag. 226.

In Norfolk, ashes are not in estimation as a manure; even those of the hearth are in a degree neglected. The meadows and fens abound with peat-bogs, which in some places would be considered as inestimable sources of manure. The peat in the meadows would no doubt afford an ample supply of ashes. *Marshall's Rural Economy of Norfolk*.

Pot-

Pot-ASHES are the refuse or ashes remaining after the salt, called pot-ashes, is extracted from them.

These ashes are of great service to most sorts of land; but as they have been in a great measure deprived of their salts, it is necessary to lay them on much thicker than other ashes. A bushel and a half of these may be used for a bushel of fresh ashes: but they should always be mixed with some other light ingredient, which may be used in any quantity, if laid on very stiff land. If the land be not over stiff, they may be laid upon it with less mixture. *Bradley's Husbandry*.

Soap-ASHES are a composition of wood-ashes and lime, remaining after the soap-makers have drawn off their lye.

Soap-ashes are likewise a very valuable manure, but there is great difference in the quality and effects of them. Those from wood-ashes are the weakest sort of them; for the wood-ashes being very light and spongy, their salts are soon dissolved, and extracted by the lye; so that there remain but very few salts in the ashes. But when the soap-boilers make use of kelp, which they sometimes do, instead of wood-ashes, the kelp being of a harder consistence than wood-ashes, the parts of it are not so easily separated by the lye, and much more of the salts remain in the ashes. But the soap-boilers use another kind of pot-ash, called barilla, which is imported from Spain in large lumps, which are much harder than common pot-ash; and though the soap-boilers break this sort very small, and sometimes screen or sift it, much more of its salts remain in it than in the pot-ash; so that the ashes from the barilla are stronger than any other; and if the same quantity of them was laid upon land, as is commonly laid of the wood-ashes, they would burn and destroy the crop. Farmers should therefore use soap-boilers' ashes with caution, till they know their quality and strength. Wood-ashes and pot-ash are used in various places for making soap; but in and near London, very little of any but barilla. The ashes from the barilla are a strong rich manure, and sold at 5s. per cart-load. They are not now so good as formerly, the soap-makers having found means to extract more of their salts from them; as they have also the salts from the lye, which were formerly rather superior to the ashes, as a manure, and was to be had for nothing, being all thrown away as useless.

They are an excellent manure, and were first used by the Flemings with very great success. Two loads of these ashes are sufficient for an acre of arable land; and by the assistance of this manure the ground will not only yield a large crop, but may be sown yearly, without leaving it fallow at any time. They should be laid on the ground in the beginning of winter, that the rain may more easily dissolve and wash them in. Sir Hugh Platt tells us, that by manuring a piece of barren land at Bishop's-hall in Middlesex, in the year 1594, he obtained an excellent crop of summer barley; that he measured the stalk and ear of one of these plants, and found it to be an ell and three inches in length, from the ground to the summit of the ear. We have given a figure of this ear of summer barley in its natural size, on plate III. fig. I. *Platt's Jewel-house of Art and Nature*.

A writer in the *Museum Rusticum* declares, that he has for many years past received great benefit by using soap-ashes as a manure, with which he almost constantly dresses his wheat lands; but never uses it alone, on account of its hot burning quality.

"My method, adds he, is to make a large heap of dung and earth, that is, two loads of earth to one of dung, placed in alternate layers to rot. After this has undergone a strong fermentation, I cause the whole heap to be turned and well mixed, leaving it for some time longer to mellow.

"I then procure the soap-ashes, and mix them with the compost, in the proportion of one-load of ashes to ten of the compost, leaving, for some time, the whole to mellow together.

"When wheat seed-time comes, about the latter end of September, I cause about ten cart-loads of this rich compost to be laid in little heaps on each acre of the land I intend to sow with wheat: this manure is immediately spread, and, sowing my wheat broad-cast, I plough it in together with the compost.

"The advantage resulting from this practice, on stiff soils, are many; and particularly, if the farmer is the least careful in preparing his tilth, he will have a clean crop, free from smut or weeds; a matter of no small consequence to him.

"I have tried this manure on lighter lands, and find it answer extremely well, provided it has lain a considerable time in the compost heap, to mellow and abate its natural

heat; but it agrees best by far with clayey soils, and in such is well worthy of being recommended as an excellent dressing for a wheat crop." *Museum Rust. vol. IV. pag. 339.*

Turf-ASHES are a good manure, but much inferior to peat-ashes. Of this I saw once a remarkable instance. A field, whereof the soil was a poor gravel, and had a crop of the broad or red clover growing upon it, was dressed one side of it with peat-ashes, and the other side with turf-ashes; the farmer laid upon this field all the ashes he had of these two sorts, and the middle of the field had no dressing. The clover in the middle part not dressed was a very poor crop, the plants being short, yellow, and stunted. The side dressed with turf-ashes was much better than the middle, the plants being taller, of a better colour, and promised to be double the crop of the undressed: but that side dressed with peat-ashes, produced a crop that appeared to be as much superior to the part dressed with the turf-ashes, as this last was superior to the middle that had no dressing. The ashes were sown upon the clover by hand, and the improvement made upon the clover was so great, that the cast of the sower's hand was extremely plain next to the middle, and appeared like an indenture: and the vigour of the plants there, was so much greater than the undressed plants, that the extent of the peat-ashes might be plainly distinguished almost to an inch. This observation was made in the beginning of summer before the clover had arrived to its full growth.

Turf ASHES, are the ashes procured by burning turfs, or the parings of the surface of heathy and moorish land. See the article BURN-BAKING.

These parings, or turfs, are cut in a dry season, and set up to dry thoroughly, leaning one against another; and, when dry, are piled into small heaps or piles, about a quarter or half a load, in each, carried up exactly square to a certain height, and then drawn up gradually in a pyramidal manner, so as to throw off any accidental showers. In a very dry season even the covering of these piles may be carried home, and stacked or housed indiscriminately with the rest; but in a wetter season it is usual to separate and dry those topmost turfs, if the weather allows, and to stack them separately, to be used on the tops of fires, when large, as dampers. A stout labourer will, in a day, cut two waggon-loads of these turfs. The women and children can set them up to dry, and the women can pile them up.

These ashes, (in the moors of Yorkshire, where, as the Rev. Mr. Comber informs us they are greatly used, the principal firing being turfs) are carried out daily, or once in two or three days, to the dunghill; and the farmer takes the opportunity of his first leisure towards the end of the year, to carry them out to his meadow land, on which he lays them thicker or thinner, as he has more or less land which he apprehends to want them, or more or less of them. The first rains wash them in, and the next summer never fails to shew their good effect.

It will be easily imagined, that as these ashes are much finer, or more pulverised than those of coals, so they insinuate themselves more into the soil, but are in their effects much less lasting. However, as every year brings a considerable supply, the farmer is less concerned that they are not a lasting manure.

In the moors of Yorkshire, the farmer is so sensible of the efficacy of these ashes, that it is become a proverb among them, "The better fire, the richer farmer." In consequence of this principle, the farmer endeavours to procure all the ashes he can from the cottagers who have no land. And hence a happy connection arises; for the poor cottager finding the article of carriage the chief part of the expence of his fuel, is wise enough to bargain with the farmer to bring him home such a quantity of his turfs in consequence of his ashes.

Some farmers lay these ashes on their ground in the spring; and if showers follow, they will have their effect in the summer crop, though not so great as if they had been laid on at the end of the year. It must however be remarked, that he who lays on his ashes in the spring, lays on what has been very lately made in the winter; and he who lays on at the latter end of the year, lays on what has been evaporating during the whole summer; so that it is not easy to say which method is the better. *Museum Rusticum, vol. V. p. 311.*

ASPEN-TREE, a species of the poplar, and called by botanists, *populus foliis subrotundis dentato angulatis utrinque glabris*. Poplar-tree with roundish leaves, having an angular indenture, and smooth on both sides.

The leaves of this tree stand upon long slender foot-stalks,

stalks, so as to be shaken by the least wind, from whence it has been called the trembling poplar, or aspen-tree.

The method of cultivating this tree is the same in every respect as that of the abele-tree. See ABELE-TREE.

ASS, a creature well known in most parts of Europe, and proves very useful in many respects, if taken proper care of.

The horse is trained up, great care is taken of him, he is instructed and exercised; while the poor ass is left to the brutality of the meanest servants, and the wantonness of children, that so far from improving, he must be a loser by his education; and indeed, had he not a large fund of good qualities, the manner in which he is treated is sufficient to exhaust them. He is the sport, the butt, and the drudge of the vulgar; who, without the least thought or concern, drive him along with a cudgel, beating, overloading, and tiring him. We do not remember, that, if there were no horses, the ass would be considered both with regard to himself and us, as the most useful, most beautiful, and most distinguished of animals. Instead of being the first, he is now the second; and from this accident alone he is held in no estimation. It is the comparison that degrades him: he is considered, not in himself, but relatively to the horse. We forget that he is an ass; that he has all the qualities of his nature, all the gifts annexed to his species; and think only on the figure and qualities of the horse which are wanting in him, and which it would be improper for him to have.

By his natural temper he is as humble, as patient, and as quiet, as the horse is proud, fiery, and impetuous; he bears with firmness, and perhaps with courage, blows and chastisements. He is sober both with regard to the quantity and quality of his food, contenting himself with the most harsh and disagreeable herbs, which the horse and other animals will not touch. In water he is very nice, drinking only of that which is perfectly clear, and at brooks with which he is acquainted. *Buffon's Hist. Naturelle, tom. IV.*

The ass, though a contemptible creature, is very serviceable to many that are not able to buy or keep horses; especially where they live near heaths or commons, the barrenest of which will keep them, being contented with any trash, dry leaves, stalks, thistles, briars, chaff, and any sort of straw is excellent food for them; they require very little looking after, and will sustain labour, hunger, and thirst, beyond most creatures. They are seldom or never sick; and endure longer than any other creature. They may be made use of to plough light lands, to carry burdens, to draw in mills, for which they are very excellent, to fetch water, or any other odd things. They are very useful for their milk, which is an excellent restorative in consumptions, and other weaknesses: but they would be of much more advantage were they used, as they are in foreign countries, for the breeding of mules. See the article MULE.

The she-ass, if you have any regard to their breed, should be covered between the months of March and June. The best age to breed from, is from three years old to ten, and you should let the young ass suck two years, and not work them till they are three years old.

Those are reckoned the best shape that are well squared, have large eyes, wide nostrils, long necks, broad breasts, high shoulders, a great back, short tail, the hair sleek and of a blackish colour: their skins make the most durable shoes of any sort of leather. *Mortimer's Husbandry, vol. I. pag. 222.*

ASTHMA. See BROKEN-WINDED.

ATMOSPHERE, the vast body, or collection of air which surrounds the earth to a very considerable height.

Clouds, which are precipitated in drops of rain for the service of mankind, do not consist wholly of watry particles; for besides aqueous vapours and what these contain, there are raised from the surface of the earth into the air, sulphureous and saline particles, which are also carried up into the clouds, and mixed with the aqueous vapours. Here we have a mixture of all such substances, as it were, in their extremely small parts, floating in the air together; and the effects of these sulphureous and saline particles, thus mingled with aqueous vapours, are sometimes very sensible, especially in thunder and lightning; when the sulphureous and nitrous particles taking fire, by the motion arising from heat, break out with the violence of flashes and noise, very much resembling the effects of gunpowder.

Another proof that there are nitrous particles raised into the air, we have in the nourishment which rain, replete with these ingredients, give to plants more than any other

water; and also from the collection of nitre or saltpetre in heaps of earth, out of which these principles derived from rain are known to be extracted, if these heaps of earth be exposed to the air, so as to keep the wet weather from spoiling the operation. It is also a convincing argument, that these nutritive ingredients are of consequence in vegetation, by plants in water refusing to grow in drouthy weather, notwithstanding they have such plenty of moisture; from their being absolutely at a stand when rain has been long a stranger to the earth, they are plainly seen to go forward with the business of vegetation, like those plants which have been deprived of motion or growth, when the fine showers descend, and continue to do so for some time.

Here then, in both cases of the plants in a pond, there is water, but there are only in one these vegetative principles, which give motion to the plants, and consequently those ingredients are absolutely necessary to vegetation; and therefore we may conclude, that water, when properly diluted by fermentation at the roots, is only an assistant to plants, in applying those necessary principles, or helping to conduct them through the tubular interstices of the fibres, or to float the nitrous particles through the whole system of the operation in motion, or growth of vegetables, and not the food itself, or any sort of nourishment, when divested of those principles. Whether, therefore, the system of exceeding fine fibres, or tubes of a plant at a stand in a pond, in a very drouthy season, admits that water undiluted, for want of nutritive or fermenting principles, into its body, during the great want of rain; or whether it absolutely refuses to imbibe, or cannot attract, for want of a finer division of its parts, any of it, as there are in it no nutritive ingredients, does not seem to admit of any doubt in favour of the latter question, which, if true in nature, may possibly be of service in the growth of some sorts of plants, and perhaps save much trouble in attempting to force others forwards with some sort of water.

Since it is plain that there is a vast quantity of nitrous, sulphureous, and bituminous matter all over the surface of the earth, and that plants and animals abound with volatile salts, we need not wonder that the heat of the sun fills the air with such fine particles, and all sorts of unctuous exhalations, by first expanding them, after which they rise till they meet with air and other mixtures of the same specific gravity. What are usually called *ignes fatui*, seem to consist of a more unctuous substance than other exhalations, for we find their oily particles are easily fixed, but not so soon spent as those of sulphur and nitre. Shooting stars are improperly so called, because they are nothing more than exhalations kindled in the air; and if a long train of substances take fire at once, it is commonly termed *a dart*; and if there be many, and they continue in the same place, they are then called *beams*.

Thus we plainly see how full the atmosphere is of these rich ingredients for the business of vegetation; and because they are of such vast consequence to the growth of plants, we will enumerate the sources of them upon the frame of the globe; from whence the sun and wind borrow them, in order to disperse them properly in the air, that they may intimately mix, and descend with the rain-drops, and so be conveyed to the mouths of the fibrous tubes of plants, with the greatest care and skill: from these ingredients first leaving the surface of the earth, through the whole process of their various motions, configurations, and combinations, till they are prepared in the most exquisite manner to be received into the bowels of vegetables, which we plainly see stand in great need of them, as without their friendly assistance, or some compositions of dung to resemble them, they are unable from water and earth alone to go forward to maturity.

Salts are of various kinds, but all have a sharp pungent taste, though not all alike; and of these some are dug out of the earth like stone out of a quarry; others are made by art, by letting the sea-water into shallow pits on the shore, and continue there till the aqueous particles are exhaled by the sun and wind, and then the salt remains at the bottom. The salt is in its nature the same in both cases; for the saline particles are not made by art in the combination of ingredients to imitate it; they are only separated from the watry particles wherein they floated. The qualities of this excellent ingredient in vegetation are, that it easily dissolves and melts readily in the open air, if it be refined from all heterogeneous matter; when the water wherewith it is entangled is any ways drawn off, there remains a gross sediment, but the finer parts are carried away with it: this sediment

ament is the only part the fire cannot melt, but reduces it to a calx.

This facility of the finer parts swimming, as they are specifically lighter than water, contributes to the benefit of plants; or rather these fine saline particles are of the same specific gravity with the water; that they may intimately mix with it, and be carried in those vapours through all the necessary stages, till they return to the earth again. This quality of melting and dissolving in water and air, sets the finer parts at liberty, and prepares them to take wing with the common exhalations. And yet the sediment, or grosser parts, which are left behind, have their excellent uses in helping the embryos of plants to send out their fibrous tubes; in search after more refined particles, which either adhere to the superficies of the particles of earth or air contained in their internal pores.

Nitre, of which there are several sorts, natural and artificial, the former refining itself, and the latter refined by art, is a kind of salt, which easily takes fire, but like sea-salt is easily reducible to a calx. The vapours, or particles of nitre, when they descend for the use of plants, are found to contain abundance of spirits; for the nitre, as a salt, is impregnated with them, which render it volatile, and the fluid extracted from it is very sharp and corrosive. The calx to which nitre is reducible, as well as the calx of common salt, has its excellent use in vegetation; and when it is reduced by fire to this state, it then takes the name of fixed salt, or rather the ashes of salts: the benefit of this calcination to land is manifest from the ashes of burnt vegetables, and other natural bodies reducible to a calx: for the rich principles, or food, if we may call it so, of vegetables, are contained more or less in all bodies whose parts can be thus separated; as is evident from the operations in chemistry, which reduce bodies to their component parts, by the help of fire.

Sulphur is a liquid clammy substance, whose parts are soon separated, and rise up into the air with other vapours, and soon occasions violent motions in the atmosphere, and becomes entombed in the aqueous particles, and is with the rain brought down to the plants. Bitumen is pretty much of the same nature with sulphur, and with it is found in great plenty in most bodies, but in the most remarkable manner, and in the greatest quantities, in pit-coal; yet not in equal quantities, as some coals burn better than others, and consequently may contain more or less of these principles, which are apt to burn. Naptha is a kind of bitumen, and the only difference is, that it takes fire sooner than bitumen is observed to do, and is not so easily quenched; and this facility of admitting the heating particles, which throw these inflammatory bodies into a speedy motion internally, is of great use in the different degrees of the plant's growth.

Maltha seems to be a species of naptha; its properties, as they appear to common observation, are, that if it touches any thing, it sticks so fast to it, as not easily to be separated; and water thrown on it in moderate quantities, does but the more inflame it, and earth alone is able to quench it. This valuable ingredient, when it descends in the drops of rain, adheres very intimately to the internal parts of the soil, both in the superficies and the concave parts of the pores; and other descents of rain increase the motion of the internal parts of the particles of maltha, and thereby promote a fine dilatation in the tubular interstices of the fibres of plants, and duly contribute to the acceleration of that motion in them, which is necessary to the different stages of their growth and nourishment. Before the fine parts of the maltha are in readiness, or duly prepared by moisture, and their well regulated fermentation, and while it is waiting for the descent of more rain, it is divested of all internal motion, and confined as a prisoner, till the other requisites to the plant's welfare are properly assembled, and ready to perform their offices.

These are the chief materials which give motion to plants, and of which the latter are found to consist, when they are analysed, unfolded, or separated into their component parts by chemistry. The professors of that art call the volatile spirits, sulphur, and saline particles, the active principles; because these, when duly prepared, and exactly applied to the mouths of the fibres, become the sole agents, and by their continual motion cause the whole action of the plant.

The vapours thus raised from the surface of the earth, become the original matter of all meteors, or heterogenous substances, fit for the production of the vegetable world; and consequently an instrument in the wise appointment of

Divine Providence, for the preservation of man, and all subordinate animals. When these heterogeneous vapours are thus lifted up above the earth, one degree of cold condenses them into larger globules, which then becoming specifically heavier than the atmosphere, fall in drops of rain, and bring down all those treasures intombed in them. A greater degree of cold produces a coagulation of the heterogeneous vapours, which shoot like salts into various forms, united into certain angles; and make the flakes of snow, which still contain the nutritive principles.

A third, or still greater degree of cold, combines the vapours into a harder substance, wherein the valuable ingredients are intombed, and they descend in what we call hail; but if the cold condenses the vapours before they rise high above the surface of the earth, they will be unable to ascend, but will hover about, and fill the lower part of the atmosphere with what is usually called a fog or mist; and if the cold be still more intense, the mist is frozen to every twig and blade of grass in form of a white incrustation, which is called rime. When the air in the day-time is warm, and the vapours buoyed up in it are too fine to be then visible, they will be condensed by the coolness of the evening, and descend on the vegetables in the form of dew; and if the evening of such a fine day be cold enough to freeze, then, instead of a dew, the surface of the ground will be covered with what is commonly called a white frost. These are the various ways appointed to bring down again upon the earth the treasures that were taken from it, in order to be prepared and properly spread over the globe, by methods and contrivances equally beautiful and surprising; and all this for the supply of needy man, who is, when these blessings are for a considerable time withheld from him, turned to destruction.

But among the riches of the atmosphere for the production of vegetables, we must not forget the consequences which the air itself is of to them; as we have already observed under the article air. See AIR. *Randall's Semi-Virgilian Husbandry.*

AVENUE, a walk planted on each side with trees, leading to an house, wood, &c.

The English elm will do in all grounds, except such as are very wet and shallow; and this is preferred to all other trees, because it will bear cutting, heading, or lopping in any manner, better than most others. The rough or smooth Dutch elm is approved by some, because of its quick growth: this is a tree that will bear removing very well; it is also green almost as soon as any plant whatever in spring, and continues so as long as any, and it makes an incomparable hedge, and is preferable to all other trees for lofty espaliers. The lime is valued for its regular growth, and fine shade: the horse-chestnut is proper for all places that are not too much exposed to rough winds. The common chestnut will do very well in a good soil, and rises to a considerable height; when planted somewhat close, though, when it stands single; it is rather inclined to spread than grow tall. The beech is a beautiful tree, and naturally grows well with us in its wild state, but it is less to be chosen for avenues than the before-mentioned, because it does not bear transplanting well, but is very subject to miscarry. Lastly, the ash is fit for any soil, and is the quickest grower of any forest-tree. It seldom fails in transplanting, and succeeds very well in wet soils, in which the others are apt to fail. The oak is but little used for avenues, because of its slow growth.

The old method of planting avenues was with regular rows of trees, and this has been always kept till of late; but we have now a much more magnificent way of planting avenues: this is, by setting the trees in clumps or platoons, making the opening much wider than before, and placing the clumps of trees about three hundred feet distant from one another. In each of these clumps there should be planted either seven or nine trees; but it is to be observed, that this is only to be practised where the avenue is to be of some considerable length, for, in short walks, this will not appear so slightly as single rows of trees. The avenues made by clumps are fittest of all for parks. The trees in each clump should be planted thirty feet asunder, and a trench should be thrown up round the whole clump, to prevent the deer from coming to the trees to bark them. *Miller's Gard. Dict.*

AVER, a general name for a labouring beast of any kind.

AVERAGE, a term used by the farmers of many parts of England for the breaking up of corn-fields; otherwise called oddish, or roughings.

AVER-LAND, the land ploughed by the tenants for the use of their lord.

AUGUST, the eighth month of the civil year.

This month returns the countryman's expences into his pockets, and encourages him to another year's adventure. If it proves dry, warm, and free from high winds, it saves a great deal of the husbandman's expence.

You may yet twifallow, also lay on your compost or soil, on your lands intended either for barley or wheat.

Carry wood, or other fuel home, before winter approaches and renders the roads deep and heavy.

Provide good seed, and well picked, against seed-time.

Put up your ewes and cows you do not like, to fatten.

This is generally the principal harvest-month for all sorts of grain, therefore make the best use of good weather while you have it.

About the end of this month you may mow your after-grass, and also clover, faintfoin, and other French grass. Geld lambs, and make the second return of your fat sheep and cattle. *Mortimer's Husbandry, vol. II.*

AUGRE, an instrument much used by carpenters, wheelwrights, &c. for boring large round holes. It consists of a wooden handle and an iron blade, terminated with a steel bit.

A common augre may be very usefully applied to try the nature of the under soil, and layers of earth, in order to know what may be expected from them, with regard to the vegetation of plants. In order to this, three augres will be necessary; the first of them about three feet long; the second six; and the third ten. Their diameters should be near an inch, and their bits large, and capable of bringing up part of the soil they pierce. An iron handle should be fixed cross-ways to wring it into the earth; from whence the instrument must be drawn up, as often as it has pierced a new depth of about six inches, in order to cleanse the bit, and examine the soil. But the borer, an instrument invented by the marquis de Tourbilli, is much better adapted to this operation. *See the article BORER.*

AVIARY, a place set apart for the feeding and propagating birds. An aviary should be sufficiently large as to allow the birds a considerable freedom of flight; and turfed, to avoid the appearance of foulness on the floor.

AWMS, the beard of wheat or barley. The word is, in some parts of England, pronounced *ails*.

AXIS, or *axle-tree*, of a waggon, cart, &c. is the strong piece of wood or iron which supports the carriage, and round the extremities of which the wheel turns. *See the articles CART and WAGGON.*

B

BAC

BACK-SINEW, in a horse, is that strong sinew extending along the hinder part of the flank from the knee to the heel, into which it is inserted.

The back-sinew is so very subject to be hurt or strained, that it is considered as one of the most common and usual accidents that happens to a horse; it generally proceeds from hard riding upon dry grounds, and from other causes, where the roads are stony and hard, and sometimes where they are poachy.

It is easily perceived by the swelling of the sinew, which sometimes extend from the knee down to the heel; and when it is so, a horse does not care to set his foot even upon the ground; but, for the most part, in his standing, sets it before the other.

The usual way of curing this malady is with cold charges, which often succeed very well, if frequently renewed; some use curriers shavings bound round the knee with a bandage, and this also answers very well in some cases; but there is nothing either so ready or efficacious as vinegar or verjuice mixed with bole, being often in a day soaked well into the sinew warm; and if any thing of the lameness or swelling remains after this, and after the heat and inflammation is gone off, a mild blister, that has nothing corrosive in it besides the caustic salt of the flies, will, generally speaking, effectuate a cure, and bring the sinew fine.

When hot and relaxing oils mixed together are used to the back sinew, which many practitioners are fond of, because they sometimes succeed in horses that have their sinews strong and rigid, yet they are apt to engender windgalls of a bad kind, or make the veins on each side the sinew to be full and gorged; and horses have been known to be lame for two or three years together with these varixes in the veins. Blistering in this case has very little or no effect, firing through the vein till the blood comes being only sufficient to remove that weakness. After the firing, the whole leg from the knee down to the heel, and all the hollow places on both sides, must be charged with a good strengthening plaister, which will perfect a cure, especially if the horse be turned to grass for a month or five weeks, or, in

BAG

the winter, if he runs a little while in a smooth yard, where he has good dry litter. *Gibson on the Diseases of Horses.*

BACON, the flesh of a hog dried in the smoke.

A writer in the *Museum Rusticum*, vol. III. pag. 234, has given us the following method of making bacon in Somersetshire:

The season for killing hogs for bacon is between September and Christmas. When you kill a large hog for bacon, lay the sides in the salting-troughs, and sprinkle them pretty heavily with bay-salt: then leave them twenty-four hours to drain away the blood, and some of the overabounding juices.

After this take them out, wipe them very dry, and throw away the draining. Then take some fresh bay-salt, and heating it well in a large iron frying-pan, rub the meat very well with it; repeating this work every day for four days, and turning the sides every other day.

If the hog be large, keep the sides in brine, (turning them ten times) for three weeks; after which take them out, and let them be thoroughly well dried in the usual manner: if they are not fully dried, they will neither keep so well, nor eat so fine.

BADGER, the name of an animal, common in many parts of England; and called by several names, as a gray, a brock, a boreson, or a bauson.

Badgers are almost as pernicious a creature to the husbandman as a fox, though not so subtle, nor can they so easily catch their prey; but for what they can catch, as new fallen lambs, young pigs, and poultry, they are as bad. The way to catch them is with a springe, or a steel-trap, or to dig a pit across their path five feet deep, and about four feet long, making it narrow at the top and bottom, and wide in the middle. This must be covered with some small sticks and leaves, so as that the badger may fall in when he comes upon it. Some hunt them into their holes in a moon-shine night, and then dig them out. *Mortimer's Husbandry, vol. I. pag. 314.*

BAG, a name given by farriers to a medicine for recovering a horse's appetite when lost. It is done in this manner:

manner : they take an ounce of assa-fœtida, and an equal quantity of the powder of favin ; these ingredients they put into a bag, which they fasten to the horse's bits, keeping him bridled for two hours, two or three times a day : as soon as the bag is taken off, he will immediately eat. The same bag will serve a long time.

BAKING of land. If some sorts of stiff and binding land be sown dry, and a scud of rain falls before the earth has time to settle, it is observed that the crust of such land will bake, so that the corn cannot come through, to the great damage of the crop : this evil does not happen if such a scud of rain be followed by cool cloudy weather, and not hot sun-shine ; for then the earth will not be so hollow as to be baked. The best way to prevent this is, to roll it immediately after sowing, which fastens the earth together, whereby the sun has not that power of piercing into it, and consequently not of baking it.

Land of this kind should, therefore, be sown as often as possible with winter corn, such as wheat and vetches ; for if wet follows the sowing, the sun is not strong enough at that time of the year to scorch the ground up, and bind it ; and it is observed, that this sort of ground has been always lucky for vetches, probably for the above reason. *Lisle's Observations in Husbandry, vol. I. pag. 26.*

BALK, a piece of land which has been either casually overslipped, or not turned up in ploughing ; or carefully left untouched by the plough, for a boundary between lands, or some other use.

BANDS, a small parcel of the longest wheat taken from the grips, and twisted together at the ear-ends, for binding the wheat into sheaves.

The bands should be laid in the morning, that they may not crack ; for the straw will not twist after the sun is up, but will be brittle, and break off below the ears. The turning of three or four of the stubble or bottom ends of the straw to the ears of the band, helps greatly to add to its strength and toughness.

The bands for binding up the sheaves should not be spread but in fair weather, because being pressed down by the grip or two which it is necessary to lay upon them to keep them in their places, and prevent their being untwisted by the sun, they will grow sooner than any other part of the corn, if rain should come ; for they cannot dry on account of their lying undermost. But though the bands must always be made while the morning dew is upon them, the sheaves ought by no means to be bound up wet : if they are, they will certainly grow mouldy.

Farmers do not always attend sufficiently to the binding up of their sheaves, but suffer the reapers, for dispatch, to tie the bands just underneath their ears, instead of binding them at the other end ; the consequence of which is, that they will hardly hold together to be slung into the cart, and will certainly be in great danger of falling to pieces before they are thrashed.

If a little rain be foreseen in harvest time, it is best to bind the grips into sheaves as fast as they are made ; because small showers will wet the single grips so much, that they cannot be bound up, and these showers may be the forerunners of greater rains. The sheaves being bound will soon dry after such wet. But if a hard rain is foreseen, the best method is not to bind the wheat into sheaves, because they will then be wet to the bands, and must be opened again. Mr. Lisle tells us, that one of his neighbours to whom this happened, unsheafed some of his wheat to dry it, and opened it and turned it so often, that the ears broke off, whereby he lost half his corn ; caution therefore ought to be used in this case, lest by curing one evil we create a worse. *Lisle's Observations in Husbandry, vol. I. pag. 333.*

BANDS of a saddle are two pieces of iron, flat, and three fingers broad, nailed upon the bows of a saddle, one on each side, contrived to hold the bows in the situation that makes the form of a saddle.

BANE, in sheep, the same as rot. See the article ROT.

BANGLE-EARS, an imperfection in a horse, which may be remedied in the following manner : place his ears as you would have them stand, and then with two little boards, or pieces of trenchers, three fingers broad, having two long strings fastened to them, bind the ears so fast in the places where they stand, that they cannot stir ; then behind the head, and the root of the ears, you will see a great deal of empty, wrinkled skin, which you must pull up with your finger and thumb, and clip away with a pair of sharp scissars all the empty skin close by the head ; then

with a needle and red silk, stitch the two outsides of the skin together, and heal the wound with a mixture of honey and turpentine : when this is done, take away the splints that hold up the ears, and in a little time they will keep the place where you fixed them, without alteration.

BANK, a heap of earth piled up to keep out the water of a river, lake, or the sea.

Sloping banks are the best security against the encroachments of the sea, of rivers, or of lakes ; making proper allowance for the weight of water, and violence of the waves. These banks should be raised about two feet above the level of the water at the highest tides, and their strength should be proportioned to the force of the water intended to be fenced off. When a river is too much confined, it swells considerably upon a flood, and consequently requires banks of greater height and strength than would otherwise be necessary : though it will sometimes break even these, and carry all before it, if a sufficient space be not allowed for the increase of its water : but when such a space is left, the waters spread, and seldom rise more than two or three feet above their usual level. In some cases a breadth of fifteen or eighteen feet on each side may do ; but in others, fifty, eighty, or an hundred feet, or perhaps so many yards, according to the largeness of the river, must be left open for that purpose. It is best to err on the safe side ; especially as the ground that is left between the banks and the river will be far from being lost ; for it will afford good grazing in the dry seasons of the year, and may be planted with osiers, and willows, and other trees of that kind ; but these should never be planted upon the banks, lest the winds spoil and tear them, by shaking the trees, and loosening their roots.

In the isle of Ely, it is common to see great banks distant one or two hundred yards on each side from the channel of the river ; and when they are so made, they are always safe : but where the distance between the banks is narrow, there, and there only, the banks are in danger of being broken down, and the country of being overflowed.

If a considerable body of water is to be guarded against, dig a trench ten or twelve feet wide, and two or three deep, or more, according to the height of the bank required. Lay all the soil that is taken out of this trench, on that side of it which lies towards the water, and leave a space of two or three feet between the trench and the foot of the bank. Let the bank be made with an easy slope of fifteen or eighteen feet in length towards the water, allowing the slope two and a half, or three feet fall to one in height ; but the inside slope need not be more than eight or nine feet, which is a foot and a half slope to one foot perpendicular. The bank thus raised five or six feet high, according as the floods require, will be two feet wide at the top, where it should be well flatted, that people may walk upon it. Let it then be covered with gravel dug out of the channel of the water, by which means the river will be deepened, and the bank rendered stronger ; and to add to the latter, sow it very thick with grass-seed. This will be found much better than turving it with the sods taken from off the trench, or some neighbouring ground ; because the sods are apt to shrink, open, and part from one another in dry weather, and are then liable to be washed away with the next flood ; whereas in thus much cheaper way, a close covering of grass, even long enough to mow, will be formed in a month or two ; far fitter than sods to break the surface of the bank ; for any tolerable soil may be very soon brought to have a coat of grass, by only raking it fine, and sowing it with grass-seeds. In a week or ten days in the spring, or summer, the grass will be up, and grow to such a height in a month or six weeks, as to be fit for mowing.

Some have attempted to guard against inundations by building walls of stone and lime, where the materials are in plenty. The great danger here is their being undermined, and that chiefly by the waters striking with force against the bottom, upon meeting with resistance from the wall. But this may be easily guarded against by laying a row of flat stones lower than the bottom of the river ; for the water striking against these stones, turns off without any danger to the foundation.

The broad trench within the bank, besides affording materials for making the bank and slopes, is attended with the farther advantage of serving for a drain to the inland ground. These trenches should always be carried as far as the banks, particularly when these are intended to fence off a rising tide ; and in the lowest part of the ground a sluice with a valve, flap-door, or flood-gate, should be placed in the

the bank, where it will both discharge the inland water, when the tide is out, and prevent its flowing in. The season of the year freest from floods should be chosen for making these banks, that the bank may have time to settle and grow firm before the heavy rains come on. It is also advisable to be as expeditious as possible in this work. For if it be begun in a dry summer, and finished in a month or two, there will be little danger of being interrupted by extraordinary floods or violent storms, either of which might do more harm in one day than could be repaired in a fortnight.

The exact dimensions of the bank, and of the ditch within it, cannot be precisely ascertained by any general rule; because both tides and floods rise to different heights, and have different force in different places and circumstances. The strength above-mentioned may be sufficient for banks in common cases; but in others, where a great body of water, or a powerful tide is to be opposed, they may be, as the memoirs of the Berne Society (*tom. II. part II. pag. 262.*) advise, four feet or more wide at the top, with a basis proportioned to their height, as three and a half are to one; or, if it be desired to make them still more solid, as four to one; so that if the bank be four feet and a half high, its basis in the former case will be fourteen feet wide, and in the latter eighteen.

The Dublin Society for the advancement of agriculture informs us (*Numb. XVII. for April 1737*) that "Lord Limerick has recovered between four and five hundred acres of very rich salt-marsh, at Dundalk in Ireland, and effectually secured them from the sea, by such banks as are above described; and by the same method many hundred thousand acres have been recovered from the sea in Cambridgeshire, Lincolnshire, and other parts of England; not to mention the low lands of Holland, which are indeed secured against the violence of the sea by no other means.

"If there be a necessity for making banks on a strand where nothing but sand can be met with, those banks should be large, and the slope very broad and extended; and if grass seed will not grow on them, let sea-weeds be planted. These with sticking furze, straw, or lopping of trees, will help to keep the banks together."

But a better method, and more effectual, is given by Dr. Hales in the Philosophical Transactions, from the experience of Dr. Wark, a clergyman in Scotland. The method consists in fixing to the bottom of the channel, a breadth of furze proportioned to the force it is to resist. The sand or slime, as either abounds, will soon settle among the branches of the furze; and when the first bed of the furze is thus interwoven or covered, another bed of furze is to be laid on as before, and so on, till the bank is raised to a sufficient height. Dr. Wark assures us, that by this simple method a bank was made near Holy-island so strong, that it became a bar against the sea itself.

"It sometimes happens, that the sea flows in through a narrow gut or passage, by which the inland waters are discharged, and then extends itself, and covers a great deal of ground. When this happens, if the inland waters cannot be diverted into another course, since a passage must be left for their discharge; let a strong sluice be fixed in the lowest part of the channel, with large piers of stone, running out for its support, and a strong foundation of wood or broad stones for the water to run over. When this is done, let the banks of sand, or other soil near at hand, be made in the manner already mentioned, on each side of the sluice.

"The reason why it is advised, in places where a sluice is to be made, to begin the work by this rather than by the bank, is, that while the tides have liberty to flow in and out at a great breadth, the sluice may be made in any part of the channel, without being much incommoded by the tide; whereas if it be deferred till the banks on each side are made, the force of the tide, when confined to a narrow passage, will tear up all before it, and render the building of the sluice impracticable: and upon the same account, the banks should be begun at the lowest part of the channel, and carried on from thence to the upper grounds.

"If, by any accident, the waters should swell so high as to overflow and tear the banks, farther mischief may be prevented by fixing with all expedition, a sail-cloth, or sheet of linen at the bottom of the bank, where the flood breaks in; for if this be done in time, the water will flow over the cloth, without washing away the bank.

"In every improvement, the expence should be particularly considered. That of making banks in this method is small. In low grounds the soil is soft, and dug with

ease, and all the work may be done with the spade and shovel, without pick-axes, which must be used in upland ground; and the materials are on the spot. All the charge will be often more than repaid by the first year's improved crop of grass; and the safety of the meadows. The produce of succeeding years will amount much higher, and the husbandman will be out of all danger for the future of having his lands overflowed and spoiled. Farmers have frequently sustained more damage from the hay destroyed in one season by floods, than the whole value of what it would have cost them to inclose and bank their meadows, and free them from all hazards."

BANQUET, is that small part of the branch of the bridle that is under the eye, which being rounded like a small rod, gathers and joins the extremities of the bit to the branch, and that in such a manner, that the banquet is not seen, but covered by the cap, or that part of the bit which is next the branch.

To BAR a vein, implies an operation in farriery performed in the following manner: they open the skin above and below the place where the operation is to be performed, and after freeing the vein from the surrounding parts, they tie it at those openings with two ligatures; after which they open the vein between the ligatures in order to discharge the blood. This operation is performed upon the veins of a horse's leg, and other parts of his body, in order to stop the course, and lessen the quantity of malignant humours that prevail there.

BARB, a general name for horses imported from Barbary.

The chest of the barb is long and slender, rises beautifully from the withers, his mane little, his head well shaped, small, and lean; his shoulders flat and slender; his withers narrow and plump; his back straight and short; and his flanks and sides round, and not bellying out; his haunches firm and well shaped; his croop generally somewhat long, and his tail placed pretty high; his thigh well shaped, and seldom flat; his leg handsome, well-shaped, and without long hair at the pastern joint; his foot well made, but his pastern often long.

Barbs are of all colours, but generally brown. They are something negligent in their goings; but, properly encouraged, shew an amazing swiftness and vigour; they are very light and fit for running; and seem of all others the fittest to breed from. It were, however, to be wished, that they were a little taller, the largest barely exceeding fourteen hands; and one of fourteen hands and an inch is very extraordinary. Experience has, however, shewn, that in England, France, &c. they get colts larger than themselves. Among the barbs, those from the king of Morocco are accounted the best, except the mountain barbs. Those of the rest of Mauritania are inferior to them, as are also those of Turkey, Persia, and Armenia. All horses from a hot climate have a smoother coat than others. *Buffon's Histoire Naturelle, tom. IV.*

BARBELS, or barbs, are excrescences or knots of superfluous flesh, growing under the tongue, and may be seen by drawing it aside.

They are cured by cutting them close off, and washing the wounded part with brandy, or salt and water. *Bartlett's Farriery, pag. 262.*

BARBERY. This shrub is in general supposed to cause the mildew in wheat, if it is growing within a short distance of the crop. Mr. Young, in his 7th volume of his Annals of Agriculture, gives the following instance in a letter from Mr. Macro: "Having heard by several farmers, that wheat would mildew where a barbery bush grew, I concluded it was only because the soil on which they naturally grew, was likewise the most natural to that distemper; I therefore sent for a plant at the distance of a mile or two, (not having any of them on my farm) and planted it on a rich soil, with a clay bottom. The bush grew well, and I, three years following, planted wheat round it. The first year, in the month of October; the second in the month of August; and the third in September; and all were so completely mildewed, that the best of the little grain it produced was only about the size of their rye, and that without any flour." This was in his garden, and more likely to mildew than on old wheat land. However he planted some on the opposite side of the garden, one of the years, which produced very good grain, although the straw was a little mildewed.

Mr. Marshall, in his Rural Economy of Norfolk, on the same subject, says, "It has long been considered as one of the first of vulgar errors among husbandmen, that the barbery plant

plant has a pernicious quality of blighting the wheat which grows near it.

This idea, whether it be erroneous or founded on fact, is no where more strongly rooted than among the Norfolk farmers; one of whom, mentioning with a serious countenance an instance of this malady, I very fashionably laughed at him. He, however, stood firm, and persisted in his being in the right; intimating, that so far from being led from the cause to the effect, he was, in the reverse, led from the effect to the cause: for observing a stripe of blasted wheat across his close, he traced it back to the hedge, thinking there to have found the enemy; but being disappointed, he crossed the lane into a garden on the opposite side of it, where he found a large barbery-bush in the direction in which he had looked for it. The mischief, according to his description, stretched away from this point across the field of wheat, growing broader and fainter (like the tail of a comet), the farther it proceeded from its source. The effect was carried to a greater distance than he had ever observed it before; owing, as he believed, to an opening in the orchard behind it to the south-west, forming a gut or channel for the wind.

Being desirous of ascertaining the fact, be it what it may, I enquired further among intelligent farmers concerning this subject.—They are, to a man, decided in their opinion as to the fact; which appears to have been so long established in the minds of principal farmers, that it is now difficult to ascertain it from observations; barbery plants having (of late years more particularly) been extirpated from farm-hedges with the utmost care and assiduity: one instance, however, of mischief, I had related to me, and another I was myself eye-witness to. Mr. William Barnard, of Bradfield, says, that seeing a patch of his wheat very much blighted, he looked round for a barbery bush; but seeing none conspicuous in the hedge, which was thick, he with some difficulty got into it, and there found the enemy. He was clearly decided as to the fact. Mr. William Gibbs, of Rowton, telling me that a patch of his wheat was blighted in the same manner, and that he believed it to proceed from some sprigs of barbery which remained in the neighbouring hedge (which a few years ago was weeded from it) I went to inspect the place; and true it was, that near it we found three small plants of barberry, one of which was particularly full of berries. The straw of the wheat is black; and the grain, if it may be so called, a mere husk of bran; while the rest of the piece was of a much superior quality. To endeavour to ascertain the truth of this opinion, I had a small bush of the barbery plant set in February or March last, in the middle of a large piece of wheat.

I neglected to make any observations upon it until a little before harvest; when a neighbour (Mr. John Baker, of South-Reps) came to tell me of the effect it had produced.

The wheat was then changing, and the rest of the piece (about twenty acres) had acquired a considerable degree of whiteness (white wheat); while about the barbery bush there appeared a long, but somewhat oval-shaped, stripe, of a dark livid colour, obvious to a person riding on the road at a considerable distance.

The part affected resembled the tail of a comet, the bush itself representing the nucleus; on one side of which the sensible effect reached about twelve yards; but on the other, not more than two yards; the tail pointing towards the south-west: so that probably the effect took place during a north-east wind.

At harvest, the ears near the bush stood erect, handling soft and chaffy; the grains slender, shrivelled and light.—As the distance from the bush increased, the effect was less discernible, until it vanished imperceptibly.

The rest of the piece was a tolerable crop; and the straw clean, except on a part which was lodged; where the straw nearly resembled that round the barbery; but the grain on that part, though lodged, was much heavier than it was on this, where the crop stood erect.

The grain of the crop, in general, was thin-bodied; nevertheless, ten grains, chosen impartially out of the ordinary corn of the piece, took twenty-four of the barbered grains, chosen equally impartially, to balance it; so that, supposing the crop in general to be worth five pounds an acre, the part injured by the barbery would barely be worth forty shillings; the quality, as well as the quantity, being much inferior.

BARKING of trees. See the article **ABLAQUEATION**.

BARK, the exterior part of trees, serving them for a skin or covering

Dr. Agricola says, that the bark of a tree may be compared to the skin of an animal, which is designed for the preservation of the inward parts. It is generally of a spongy texture, and communicates with the pith, by a multiplicity of small fibres passing between the capillary tubes, of which the wood consists; so that the roots having imbibed the proper nutriment of the tree, it is carried up by the warmth of the sun, through the fine arterial vessels of the tree to the top of it; and being there condensed by the cold, it returns by its own gravity down by the vessels which lie between the wood and the inner bark, which perform the office of veins; and as it passes by, leaves such part of its juices as the texture of the bark will receive, and requires for its support.

Some are of opinion, that the soft whitish rind, or substance which lies between the inner bark and the wood, performs the office of veins; and some call this a third bark, supposing it to differ from the other only in having its fibres closer; adding, that this is the part which contains the liquid sap, gums, &c. found in plants during the spring and summer months, and which hardening by degrees, is imperceptibly conveyed into the woody part of the tree, forming every year a new circle of wood between the bark and the trunk. These circles are not equally thick, that circumstance depending on the fertility of the year.

The bark of trees in general, and especially that of the oak, contains a very rich salt, extremely useful in vegetation. One load of oak bark laid in a heap and rotted, after the tanners have used it for dressing their leather, will do more service to stiff cold land, and its effects will last longer, than two loads of the richest dung. Mr. Miller says it is much better for cold strong land, than for light hot ground, if it be used alone, as taken from the tan-yard; because it is of a warm nature, and will loosen and separate the earth so effectually, that, by only using it two or three times, a strong soil, not easy to be wrought, will be rendered perfectly light and loose: but by mixing it with earth of a nature contrary to that which it is intended to correct, and in a proportion suited to the nature of the soil it is to be laid on, it will prove a fine manure for almost any land; its salts being such as will always fertilize the ground. Mr. Mortimer asserts, that it will alter and change the very nature of the soil, and turn it into a very rich black mould. *Mortimer's Husbandry*, vol. I. p. 121.

It necessarily abounds in vegetable parts, derived from the tree to which it once belonged; and cannot but be strongly impregnated with animal juices, as it lies a long time in the tan vats, with the skins and hides of animals; circumstances which must render it singularly beneficial to all poor lands.

If laid on grass, it should be spread soon after Michaelmas, that the winter rains may wash it into the ground: for if it be laid on in the spring, it will be apt to burn the grass, and, instead of improving, will do it a considerable injury for that season. When used for corn land it should be spread before the last ploughing, that it may be turned down for the fibres of the corn to reach it in the spring; for if it lies too near the surface it will forward the growth of the corn in winter; and in the spring, when the nourishment is chiefly wanted to encourage the growth of the plants, it will be so nearly consumed, that the corn will receive very little advantage from it.

Mr. Bradley tells us, that he advised a gentleman, to whom a considerable quantity of bark was left upon the expiration of the lease of a tan-yard, to lay some of it upon a piece of stubborn sour land, which he did with such success, that his product was admired by all the gardeners and farmers in the neighbourhood. For such ground, he thinks it should be mixed with a sandy soil; and that one third of bark to two thirds of sand, will be a very sufficient proportion for clays; laying on about one hundred and fifty cart loads upon an acre. *Bradley's Husbandry*, p. 90.

All barks or rinds of trees, though not of so high a value as that of the oak, which is the sort principally used by tanners, must of necessity enrich either corn or pasture ground, if broken into small pieces, and laid upon it. They must needs be much richer than the mould or earth, usually found in the bodies of old, large, hollow, willow-trees, though this is justly esteemed very efficacious. *Forlidge's Husbandry*, p. 84.

For the manner of making hot-beds with tanner's bark, see the article TAN.

BARK-BOUND, a disease common to fruit-trees, and may be cured by making a slit through the bark, from the top of the tree to the bottom, in February or March; and if the gaping be pretty considerable, fill up the rift with cow-dung. *Mortimer's Husbandry*, vol. II. p. 85.

BARKING of trees, the operation of stripping off the bark or rind, particularly that of the oak, for the use of tanners.

It is necessary in our climate to perform this operation in the month of May, because at that season only, the bark is, by the great quantity of sap, easily separated from the wood. This also renders it necessary to fell the trees in that month; but by this method the timber is much less valuable than it would be, if felled after the fall of the leaf.

Mr. Marshall, in his *Rural Economy of Yorkshire*, says, the peeling of oak timber in that county is generally done by the day; the labourers being, I believe, invariably employed by the timber-merchant, not by the tanner; practices which are productive of a considerable saving of bark. Men working by the ton or the quarter, or tanners paying by weight or measure, will not peel the boughs sufficiently near; it is against their interest to do it. But it is the interest of the timber-merchant, or of the tanner, if he purchase by the gross, or by the ton of timber, to peel so long as the bark will pay for the labour. This accounts for the smallness of the twigs which are peeled in this country: if the bark run freely, twigs not much thicker than the finger are frequently stripped.

The tool commonly made use of, in some counties, is of bone. The thigh or shin-bone of an ass are preferred, formed into a two-handed instrument for the stem and larger boughs, with an handle of wood fixed at the end. The edge once given by the grinding-stone, or a rasp, keeps itself sharp by wear.

The method of drying bark in this country is generally the common one of seating it in a leaning posture against poles lying horizontally, on forked stakes. But in a wet season, or when the ground is naturally moist, it is laid across a line of topwood, formed into a kind of banklet, raising the bark about a foot from the ground. By this practice no part of the bark is suffered to touch the ground: and it is, perhaps, upon the whole, the best practice, in all seasons and situations. He then stacks or houses it; and generally shaves and chops it ready for the tan-pit; selling it to the tanner at so much a quarter.

This custom appears to be founded on a false basis: the tanner is, or ought to be, the best judge of the mode of preparation, and the operation ought to pass under his eye.

The practice of grinding bark does not seem to have yet got footing in this district: whenever it does, it will of course bring the preparation of bark into its proper channel.

The medium price of chopt bark, is 10s. 6d. a quarter.

BARLEY, a species of grain well known in England, and of which Mr. Miller has enumerated four species.

1. The spring barley, which has a double row of beards or awns standing erect. This is the sort principally cultivated in England, and of which the farmers make two sorts, viz. the common, and the rath-ripe barley: but these two sorts are in reality the same; for the rath-ripe is only an alteration of the common barley, occasioned by being long cultivated upon warm gravelly lands. The seeds of this, when sown in cold or strong land, will, the first year, ripen near a fortnight earlier than the seeds taken from strong land, and therefore the farmers in the vales generally purchase their seed barley from the warm lands; for if sown in the vales two or three years, it will become full as late in ripening as the common barley of their own product: on the other hand, the farmers on the warm land are also obliged to procure their seed barley from the strong land, otherwise their grain would degenerate in bulk or fullness, which, by this change, is prevented. This sort of barley is easily distinguished by the two orders of beards or awns, which stand erect; the rind is also much thinner, and therefore esteemed better for making malt.

2. The long-eared barley, which is cultivated in many parts of England, and is an exceeding good sort; but some farmers object to this barley, because they say the ears being long and heavy, it is more apt to lodge. This sort of barley hath its grains regularly ranged in a double row, lying over each other, like the tiles on a house, or the scales of fish. It has no beards or awns; but its rind is very thin, and therefore esteemed for making malt.

3. The sprat barley, called also Battledore, Fulham, and Putney barley, from the great quantities cultivated in the neighbourhoods of those places, has shorter and broader ears than either of the former sorts; the awns or beards are longer, which tend greatly to preserve it from the birds, and the grains placed closer together. This seldom grows so tall as the other species; the straw is also coarser, and therefore not so good fodder for cattle.

4. The winter barley, called also square-barley, bear-barley, or big, is seldom cultivated in the southern parts of England; but in the northern counties, and in Scotland, it is the general sort sown, as being much hardier than the other species. There are two sorts of this barley, the one with four rows of grains, and the other with six, the latter of which is commonly distinguished by the name of barley-big. The grain is large and plump, but the rind or chaff of it being thicker than that of either of the preceding sorts, it is less esteemed for making malt, and therefore not cultivated in the southern parts of England, where the sorts which are so much better for that purpose thrive so well.

Both the four and six rowed barley are generally sown in the autumn, nearly at the same time with wheat, not only in temperate climates, but also in very cold countries; their hardiness being such as to bear the winter's frosts, even in the mountainous parts of the northern regions. In hot countries they are sown in January, February, and March.

All the other sorts are sown in the spring of the year in a dry time: in some very light land, barley is sown early in March, but, in strong clay soils, not till April, and sometimes not till the beginning of May; but when it is sown so late, if the season does not prove very favourable, it is very late in autumn before it is fit to mow, unless it be the rath-ripe sort, which is often ripe in nine weeks from the time of sowing: though Mr. Lisle is of opinion, that this, in particular, ought to be sown early, for otherwise it will grow very thin. He likewise thinks that it should be sown on better ground than the other barley, because as it ripens in a shorter time, it may be naturally supposed to exhaust the nutritive juices of the earth faster than other corn. But it is said by others, that these nutritive juices in almost any tolerable soil, will probably hold out long enough to feed a crop of so short a standing as this is, though they might not suffice for corn which should remain longer upon the ground; and it is added, that about Putney in Wiltshire, they sow the poorest sandy ground with rath-ripe barley. *Lisle's Husbandry*, vol. I. p. 271.

Mr. Lisle adds, that he himself, in the year 1707, sowed in Hampshire, rath-ripe barley in very poor white ground, and some of the same corn in good strong clay land. No rain fell to bring it up till June; after which there were frequent showers, and plenty of rain till harvest. His rath-ripe barley in the poor land was miserably bent, broken in the straw, and harled, or fallen down. In the strong clay land, the same corn suffered the same injuries, though in a less degree: but the straw and leaves of the rath-ripe barley in both places blighted, and were full of black specks; their ears were thin, and their colour was lost; while the plants of late-ripe barley in an adjacent field were free from these spots, and stood upright with good strength. From this experiment he infers, that since the clay land in the hilly country of Hampshire, though in good heart, cannot, even in a moist year, sufficiently feed the straw of rath-ripe barley, so as to enable it to stand upright, but suffers it to be languid and withering, this sort of corn is not proper for such places, and that it is better to sow late-ripe barley, even though three or four horses extraordinary be provided against sowing time, in order to get the corn into the ground a week before May begins. *Lisle's Husbandry*, vol. I. p. 272.

Another important observation made on the same occasion, by the same judicious farmer, was, that one half of the seed which fell deep came up without rain, while the rest did not sprout till after the rain came. The half which came up first, could not, by reason of the weakness of the stems, wait for the ripening of the latter edge-grown corn, in the same field; but its straw bent, broke, and was entangled, and the ears buried themselves among the broad clover sown with the barley, so that he was forced to cut it, not being able to stay a week or ten days longer for the edge-grown corn to ripen: whereas the late-ripe barley stood so upright in its straw, that the corn which came up first would stay ten days for the edge-grown corn.

The same gentleman had another evident proof, in the year 1706, that the straw of the rath-ripe barley is thinner and

and weaker than that of the late-ripe. All his rath-ripe barley, of which he sowed fifty acres in different sorts of ground, are some of it side by side with late-ripe barley, crumpled down in the straw, while the late-ripe barley of the same forwardness and growth stood upright.

Upon the whole, Mr. Lisle, after observing farther, that, if the ground be good, and the year a feeding one, rath-ripe barley is apt to run rank, and to fall while very green in the ear, which occasions the grain not to fill; concludes, in regard to this sort of corn, that it should always be sown early, that the land should not have a north exposure, and that the soil in which it is planted should be pretty good, either naturally such, or rendered so by art; "for we know," says he, that the poorer the ground is, the weaker and poorer the straw will be in all sorts of corn; and if the rath-ripe barley has by nature a weaker and thinner straw than the late-ripe barley, and on that account is apter to crumple, to bend down, and to break in the straw before it is ripe, much more will it be apt to do so, when the straw is made much thinner and weaker than naturally it would be by the poverty of the ground it is sown in. It is very evident to me, that rath-ripe barley ought not to be sown on poor ground, and much less so in case it lies declivous from the sun towards the north." *Lisle's Husbandry*, vol. I. p. 273, 274.

"Common barley sown once in the burning sand at Patney in Wiltshire, will, for many years after, if sown on indifferent warm ground, be ripe two or three weeks sooner than any other, which has never been impregnated at Patney: but if sown a degree farther north, on cold clayey land, will, in two or three years, lose this quality, and become as late-ripe as any other. Indeed, Patney is far from improving the species of barley, except we think it improved by becoming more weak and tender, and shorter lived; which last mentioned quality fits it for such countries, where the summers are too short for other barley to ripen.

"Barley is far from being improved by becoming rath-ripe; for it loses more good qualities than it gets by being sown at Patney. It is so tender, that if it be sown early, the frost is apt to kill it: or if it be sown late in May, on the same day, and in the same soil, with the same sort of barley that is not rath-ripe, it will be much thinner bodied than the late-ripe. And besides, if it happens to have any check, by cold or drought, it never recovers it, as the other doth, at what time soever it is sown. It is now, as I am informed, gone out of fashion, and very few farmers have sown it of late years.

"I know a little parish, that I believe formerly lost about two hundred pounds a year, by sowing rath-ripe barley. But long and dear experience hath now convinced them of their error, and obliged them totally to disuse it." *Tull's Husbandry*, p. 115, 233, 234.

The middle-ripe barley, as Mr. Lisle calls it, meaning the common spring barley, bears late sowing, even upon ground declivous from the sun, better than the rath-ripe sort; but not near so well as the late-ripe, or common long eared barley; nor will its stalk stand so long. Mr. Lisle was convinced from experience, that late-ripe barley will endure being sowed when the ground is wetter than will do for the rath-ripe sort, and that a bottom ground, or vale pent in between two hills, though shaded by one of them from the sun, will, by means of the warmth and closeness of the air, often ripen corn as fast as the ground that lies declivous to the sun. In a field which he sowed with the common spring barley, the lowest part of which laid on a flat, ripened regularly, and even sooner than another part of the same field which lay upon the side of a hill declivous to the sun: but on that side of the same hill which sloped from the sun, the corn was more edge-grown, lay backward, and neither looked so white, nor was it so ripe. *Lisle's Husbandry*, vol. I. p. 275.

The land which lies both very dry and healthy, and in which both mellowness and lightness are joined to a proper strength of soil, is that which produces the best body, and thinnest rinded barley; qualities which always recommend this grain, especially to the maltsters. Such generally is the barley of the growth of the hilly countries. But poverty of soil is by no means requisite in land, in order to its producing a plump and thin rinded barley; though it is allowed, that poor land which lies dry and warm, will bear better corn of this kind, than rich land in a cold and wet situation; for barley does not stand so much in need of strength in the land, as of the healthiness and warmth of the soil;

though both are best where they can be had. *Lisle's Husbandry*, vol. I. p. 281.

With regard to the choice of seed barley, it is necessary to observe, that the best grain for sowing is that which is not blackish at the tail, nor has a deep redness, but is of a pale lively yellow colour, intermixed with a bright whitish cast, and if the rind be a little shrivelled, it will be so much the better; for that slight shrivelling occasioned by its having sweated in the mow, is a sure indication that its coat is thin. The husk of thick rind barley being too stiff to shrink, will lie smooth and hollow, even when the inside flour has shrunk from it.

The necessity of a change of seed from time to time, by sowing that of the growth of a different soil, is no where more evident than in the culture of this grain, which otherwise becomes coarser and coarser every year. But at all times in this, as well as in all other grain, the utmost care should be taken that the seed be full bodied.

Mr. Lisle tells us, that in order to be satisfied of this, he took out of a heap of barley sixty grains, of different sizes, viz. twenty of the biggest, twenty of the middle size, and twenty of the smallest corns. Twenty of each sort of these grains he planted in three pots, each filled with the same sort of mould, which was very rich. In eight or nine days time thirteen of the fullest bodied grains were come up, nine of the middle sized, and only five of the smallest, and the plants of the plumpest corn exceeded those of the others, both in colour and breadth of blade. In three days after, he found nineteen blades of the largest sort come up, seventeen of the middle size, and thirteen of the smallest; and in three days more, the blades of the best and of the middle sort were all come up, while only seventeen of the worst had sprouted, with such manifest disadvantage in colour and strength in these last as plainly shewed that many of them would not have come up at all in poor ground. *Lisle's Husbandry*, vol. I. p. 283.

It is natural to suppose that barley will, like wheat, be benefited by being steeped before it be sown; for as rain cannot be depended upon soon after the sowing of spring corn, there is surely an equal reason for extending the practice of these sorts of grain, as well as to those which are sown in autumn. Liming indeed may hurt barley, if hot wheather should soon follow after the sowing, but a little sprinkling of soot bids fair for improving it, at least it will prevent the insects from preying upon the seed. The rev. Mr. Elliot informs us, that a farmer who was obliged to attend other business in the course of the morning, sowed oats at break of day, and harrowed them in before sun-rising. The consequence was, that the corn thus early sown, out-stripped the other oats sown on the same day after the sun was up, had larger ears, and appeared every way better, though the spot in which they grew was the worst part of the field. If the dew, when buried with the corn, had this effect, it is reasonable to suppose that a much greater would have been produced, had the seed been sown in the evening, left all night to have been softened with the dew, and then harrowed-in in the morning. *Elliot's Essay on Field Husbandry*, p. 29.

Mr. Lisle also tells us, that a maltster in Hampshire having taken lands in the beginning of May, and no barley being to be had, he, by the persuasion of his malting-servant, made use of barley he had wetted, and was just well chitted or sprouted; this corn came up well, and produced as good a crop as any sown that year. *Lisle's Husbandry*, vol. I. p. 284.

Barley is generally sown either after a fallow, or on an ersth or second crop. If after a fallow, the land must be ploughed at least three times; and at the first ploughing, it should be laid in small ridges, and in that manner remain during the winter for the frost to mellow it: but if another ploughing can be given it in January, or in the beginning of February, the ground will be still much better broken and prepared. In March these ridges are split, the ground is well harrowed, and laid as smooth as can be, and, if possible it is plowed again the same day, in order to sow. But in strong wet lands, the best way is to lay it round, and make deep furrows to receive the water.

Some at the time of twifallowing in June, make the land very fine, and sow it with turneps, which they feed sheep with in the winter: and in March they plough it up, and order it as before; but others who take this method of sowing turneps, give it only one ploughing in March, just before they sow.

Those who sow barley upon an ersth, after wheat, plough

up the wheat stubble in as dry weather as they can, as soon as the time of sowing wheat is over, which is generally about the beginning of October, and lay three ridges into one, if they have dung to spread upon it : but if they have not, they plough it in small ridges, as before directed, that it may be the drier, and be the better mellowed by the frost : they then plough it up again in March, and order it as before. Some farmers injudiciously sow their barley after oats, in which case, neither of these three ploughings ought by any means to be neglected ; and the land will be in much better order if the first of them be given in October : or, if the harvest be early, the weather dry, and the husbandman can possibly find time to do it, he will improve his ground still more, by ploughing it up before he sows his wheat, just as harvest is in : this will be half as good as a summer's fallow. But all years will not admit of this practice. *Mortimer's Husbandry, vol. I. p. 131.*

Some sow their barley on small ridges, and others on broad lands ; the latter cannot be laid too round.

Mr. Mortimer relates, that a farmer in Essex, who lived near a market-town, from whence he had good quantities of dung, used to sow his land with barley and clover ; reaped the corn at harvest, fed the clover all the winter, and from spring till the middle of July, when he fallowed his ground. In the next spring he sowed it again with barley and clover, and repeated every year this method, by which he had large crops. His land was a rich light mould, somewhat inclining to a gravelly bottom. *Mortimer's Husbandry, vol. I. p. 132.*

A correspondent of the editors of the *Museum Rusticum*, observes, that a few years ago he sowed twenty-five acres of land, in fine tilth, with broad clover and barley ; but the spring being backward and cold, and the summer wet, the clover got too forward, and overpowered the barley. At harvest they were both cut together ; and the clover being full of juice, occasioned its being a tedious time before the barley could be housed. When he got it into the barn, the men complained much of its threshing so badly, that they could not undertake to do it unless he would double the price to them : as this could not be afforded, he ordered them to give it only a light beating, leaving the under corn in the straw, together with the clover, for the cattle.

By this means he lost half his crop by the clover ; and what barley could be obtained was lean, and thin-bodied, fetching but a very indifferent price at market.

As this was not the first loss of the same kind he had experienced, he was determined, if possible, to find out some remedy ; and accordingly applied to a very intelligent farmer in the neighbourhood, who advised him to sow his clover, for the future, a month after the barley, by which means it would not prove too rank. This advice he accordingly followed, and found it answer extremely well ; and has therefore, to his great advantage, continued the practice ever since. He adds, that there is no danger of the clover failing, though the season should prove dry ; and that the seed is to be scattered on the ground without any farther care, there being no occasion to harrow or roll it ; for the small blades of the barley will keep moisture enough in the land to supply the small wants of the clover during its infant growth, and when the barley is off, it thrives surprizingly. *Museum Rusticum, vol. III. p. 315.*

Mr. Marshall, in his *Minutes of Agriculture*, says, that in a dry summer early-sown barley has a great advantage ; but, perhaps, except the soil be very clean indeed, the opportunity of an April fallow ought not to be missed.

It has been already observed, that the usual time of sowing is in March, April, or the beginning of May. It is generally thought most advisable to sow light lands the earliest, and to embrace the first dry season that offers for doing it ; dry weather being best for most summer corn. Clayey grounds, and lands subject to weeds, are thought to produce the best crops when sowed late. Mr. Mortimer says, that barley will do well when sown even about the middle of May, if the seed has been properly steeped. *Mortimer's Husbandry, vol. I. p. 132.*

The common method is to sow the barley seed with a broad-cast at two sowings ; the first being harrowed in once, the second is harrowed until the seed is buried ; the common allowance of seed is four bushels to an acre : but if the farmers could be prevailed upon to alter this practice, they would soon find their account in it ; for if a third part of that quantity ye sown, there will be a much greater pro-

duce, and the corn will be much less liable to lodge, as I (says Mr. Miller) have many times experienced ; for when corn, or any other vegetables, stand very close, the stalks are drawn up weak, and thence incapable of resisting the force of the winds, or supporting themselves under heavy rains : but when they are at a proper distance, their stalks will be more than twice the size of the other, and therefore are seldom laid. I have frequently observed in fields where there has been a foot-path through their middle, that the corn, which has stood thin on each side of the path, hath stood upright, when all the rest on both sides has been laid flat on the ground ; and whoever will give himself the trouble to examine these roots near the path, will find them tiller out (*i. e.* have a greater number of stalks) to more than four times the quantity of the other parts of the field. I have seen experiments made by sowing barley in rows across divers parts of the same field, and the grains sown thin in the rows, so that the roots were three or four inches asunder in the rows, and the rows a foot distant ; the intermediate spaces of the same field were at the same time sown broad-cast in the usual way ; the success was this : the roots which stood thin in the rows tillered out from ten or twelve, to upwards of thirty stalks on each root, the stalks were stronger, the ears longer, and the grains larger than any of those sown in the common way ; and when those parts of the field, where the corn was sown in the usual way, has been lodged, these parts sown thin have supported their upright position against wind and rain, though the rows have been made not only lengthways, but across the lands, in several positions ; so that there could be no alteration in regard to the goodness of the land, or the situation of the corn : where therefore such experiments have been made, and always attended with equal success, there can be no room to doubt which of the two methods is most eligible, since if the crops were only supposed to be equal in both, the saving two thirds of the corn sown is a very great advantage, and deserves a national consideration ; as such as a saving, in scarce times, might be of very great benefit to the public. This saving of seed-corn must be understood to regard such as is sown broad-cast ; for if it be sown in drills, an eighth part of the seed usually sown will be sufficient for an acre of land, and the produce will be greater ; for all sorts of corn are naturally inclined to send out several stalks from each root, which they rarely fail to do where the roots are at a proper distance, and have room ; nor do stalks grow in this case near so tall, but are much stronger than when they are near together, when they rarely have more than two or three stalks ; whereas those roots which have proper room, seldom have less than ten or twelve. I have had eighty stalks upon one root of barley, which were strong, produced long ears, and the grain was better filled than any I ever saw grow in the common method of husbandry, and the land on which this grew was not very rich ; but I have frequently observed on the sides of hot-beds in the kitchen gardens, where barley straw has been used for covering the beds, that some of the grains left in the ears have dropped out and grown, the roots have produced from thirty to sixty stalks each, and those have been four or five times larger than the stalks ever arrive at in the common way ; but to this I know it will be objected, that although upon rich ground in a garden, these roots of corn may probably have so many stalks, yet in poor land they will not have such produce ; therefore unless a greater quantity of seeds be sown, the crop will not be worth standing, which is one of the greatest fallacies that can be imagined ; for to suppose that poor land can nourish more than twice the number of roots in the same space as rich land, is such an absurdity, as one could hardly suppose any person of common understanding guilty of ; and yet so it is : for the general practice is to allow a greater quantity of seed to poor land, than for richer ground, not considering that where the roots stand so close, they will deprive each other of their nourishment, and consequently starve themselves, which is always the case when the roots stand close, which any person may at first sight observe in any part of the fields where the corn happens to scatter when they are sowing it ; or in places where by harrowing, the seed is drawn in heaps, those patches will starve, and never grow to a third part of the size as the other parts of the same field ; and yet, common as this is, it is little noticed by farmers, otherwise they surely would not continue their old custom of sowing. I have made many experiments for several years in the poorest land, and have always found that all crops, which were sown or planted

planted at a greater distance than usual, have succeeded best upon such land; and I am convinced if farmers could be prevailed upon to quit their prejudices, and make trial of this method of sowing their corn thin, they would soon see the advantage of this husbandry. *Miller's Gard. Dic.*

It is a common practice in some parts to scatter the dung of pigeons, poultry, &c. over barley and other corn, after the corn is sown; but if this method be pursued, care should be taken to scatter the dung immediately; because then the shoot will easily make its way through: but when laid on later, it burns up, and eats the blades of the young plants. *Mortimer's Husbandry, vol. I. p. 133.*

It too often happens from unfavourable weather, and an extremely dry spring, that it is impossible by the common method to break the clods, and prepare the ground sufficiently for sowing barley; in which case it has been the usual method to break the clods with a large beetle called, from its use, a clotting-beetle. But this being a very chargeable and tedious method of preparing land, induced the ingenious Mr. Randall of York, to construct an instrument, which he calls a spiky roller, by the assistance of which a large quantity of land may, in such a dry season, be soon reduced to an exceeding fine tilth, with very little trouble. The reader will find a full account of this useful instrument, the manner of making and using it, together with a figure of the roller, under the article SPIKY ROLLER.

After the barley is sown and harrowed-in, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth; which will render it better to mow the barley, and also cause the earth to be closer to the roots of the corn, which will be of great service to it in dry weather.

And also when the barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will again pass the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground, which will be of singular service in dry seasons; and this rolling of it before it stalks, will cause it to tiller out into a greater number of stalks, so that if the plants should be thin, this will cause them to spread so as to fill the ground, and likewise strengthen the stalks. *Miller's Gard. Dic.*

If the corn grows too rank, as it is sometimes thought to do in a wet spring, mowing is then much better than feeding it; because the scythe takes off only the rank tops, but the sheep feed upon all indifferently; nor should they even in any case be left upon it too long, because being particularly fond of the sweet end of the stalk next the root, they will bite so close as to injure the future growth of the plant.

Barley is ripe when the red roan, as the farmers call it, meaning a reddish colour on the ear, is gone off, when the ears droop and fall, as it were, double against the straw, and the stalks have lost their verdure. If it be full of weeds it must lie in the swarth till they are dry. It is not apt to shed; but in wet weather it will be apt to sprout or grow musty; and therefore every fair day after rain it should be shook up and turned; and when it is tolerably dry, let it be made up into cocks; but be sure never to house it till thoroughly dry, lest it mow-burn, which will make it malt worse than if it had spired in the field. The common produce of barley is two or three quarters upon an acre. *Mortimer's Husbandry, vol. I. p. 133.*

Mr. Lisle says, that poor thin barley and oats should be cut a little sooner than if the same plants were strong and vigorous; for that the straw, when the plants are full ripe, will not stand against the scythe. In this case the barley, in particular, must lie in swarth till it is thoroughly dry. Some of his barley, which lay out in swarth five or six days in very fine weather, though both blighted and edge-grown, grew plump, and acquired very near as good a colour as the best. He reckons short scythes the best for mowing lodged or crumpled corn, because they miss the fewest plants; and observes that a bow upon the scythe which carries away the swarth before it, is preferable to a cradle, the fingers of which would be pulled to pieces by the intangled corn, in drawing back the scythe. *Lisle's Husbandry, vol. I. p. 335.*

Mr. Du Hamel tells us, that a farmer at Acon, observing that the chief hopes of more than common success by means of the New Husbandry, were founded on the frequent

stirring of the ground while the corn was in it, and on allowing each plant sufficient space to extend its roots, and thereby collect the more nourishment, tried an experiment which appeared to him very proper to discover whether the effect would answer. He carefully cultivated a grain of barley, which grew by chance in his vineyard. This plant, said he, stands distant from any other: it can extend its roots every way; it is in a rich soil, and cannot want for food: by joining frequent culture to these advantages, this plant of barley, according to these principles of the New Husbandry, ought to yield a surprising increase. His reasoning was just, and the experiment confirmed it; for this single grain of barley produced two hundred ears, and about thirty stalks which had no ears. Some of the stalks were four feet high, and most of them three. Mr. Du Hamel counted twenty-four grains in a middling ear. Thus one grain, planted in a good soil, and well cultivated, produced 4800 grains; and the straw of this single plant of barley made of itself a sheaf. *Translation of Du Hamel's Husb. p. 113.*

We have already observed, under the article SOAP ASHES, that sir Hugh Platt, by spreading that manure over his land, had a surprising crop of barley, the plants of which were of a prodigious size. An ear of this barley is delineated in its natural size, Plate III. fig. 1.

Mr. Young, in his Annals of Agriculture, vol. VII. gives the following experiments by Mr. Macro on early and late sowing of barley: on Nov. 16, 1785, "I began this experiment by sowing two bushels of barley, which I harrowed-in, on clover land that had been folded the same as for the wheat; this first sowing, therefore had only one earth. The barley came up about a week sooner than the wheat, by the side of it, which was sown the same day, and was exceedingly flourishing till the first sharp frost set in, which damaged the blade, but did not seem to affect the root. As near the middle of December as the weather would permit, I sowed two bushels more, on exactly the same quantity of ground, and so on about the middle of every month, till the month of May, 1786. This, and every sowing after had two earths, one cast, or half the seed, was ploughed-in, and the other half harrowed-in; all the land was folded alike in the month of November. The second sharp frost, killed some of this sowing, (I should think most likely of the harrowed-in cast) and a good deal of that sown in November, but they both, with that sown in January, seemed to suffer still more, by the sharp cutting winds in the month of March, when there was no snow to cover the blade; and it was injured by the frost, the sowings in February and March, lost few, if any of their plants, and what was somewhat remarkable, were both forward enough to be harvested on the same day, with the three preceding sowings. That sown in April, was full a fortnight later, and that sown in May, there not being any so late sown in the neighbourhood, was entirely destroyed by vermin.

As I some years before intended trying the same experiment, but was disappointed of knowing the event by the stupidity of my workmen, I determined this time to prevent any mistakes by mixing the different parcels in the barn, to thresh enough of the different sowings in the field, to satisfy me, which was the most profitable crop, and accordingly attended the thresher the whole day myself.

As it was not at all necessary for the experiment, to thrash the whole crop, I took three swaths of each sowing, twelve yards in length, on the lowest part of the land, where I thought the soil was the most equal through the whole of the experiment, which I should have said before, were by the side of each other, on the same piece of land. I had every parcel dressed and put into a sack by itself as soon as threshed, and the account stands thus:

From that sown in November, 72 sq. yds.	Pecks.		Qrs. P.	Pints.		or, per acre.	Ccombs.		Bushels.	Pecks.	Quarts.
	3	1					12	2			
December	3	1	1				12	3	1	1	1
January	3	1	1				13				
February	2	3	2				11	2	2		
March	2	2	2				10	3	3	1	
April	2	1	2				8	3	2	1	
May	0	0	0				0	0	0		

This sowing, as I observed above, was entirely destroyed by the rooks, I believe it had not been sown more than three days before they began to scrape and pick it up, and compleatly devoured it.

It was the same with the very early sowings, but that I expected, and was guarded against. This, however, may serve as a lesson to young farmers, that although early sowing may in most cases be profitable, yet, it will not answer in large open fields, where lands are intermixed, unless neighbours sow at the same time, for if only one farmer sows early, he had need have as many keepers as he has pieces of land.

The barley of all the sowings was of the Zealand stock. On the same piece of land that I tried the above experiments, which is a deep sand, value about 6 or 7 shillings per acre, I tried two others, one about ten years since, with chalk from different pits, some of them a dry chalk, and others greasy: I carried only one load of each sort, and laid it about the thickness of 70 loads to an acre. Not one of them did the least good, for I could not tell by any of the crops since, without looking at the soil where they were laid. The other was by deep ploughing, in the autumn of 1785 (when I sowed part of the piece with wheat) by going with a second plough after the first for one scratch only) and raising about three or four inches of soil that had never been turned up before; and on viewing it about Midsummer, I could not find where it was; by any difference in the crop, nor could see that the barley sown in January was the best crop. By the same rule, when I began to try the experiment before, that sown in February was the best, as it appeared so on view, I remember, all the summer.

Mr. Marshall, in his Rural Economy of the Midland Counties, says the long-eared barley, and the sprat barley are the chief cultivated in those parts. The latter is the old stock of the country, the former of late introduction, of not more than fifty years standing. The sprat is deemed more hardy, and requires to be sown more early; the long-eared to be the better yielder. The sprat is thought by maltsters to make the best keeping beer; the long-eared to be freer, to operate quicker, both in the malt-house and the cellar. In ordinary practice barley succeeds wheat. Where turneps are grown, it precedes that crop: of late years it has been sown with success on turf. The time of sowing, if the weather permits, the latter end of April or beginning of May. The quantity of seed, two bushels and a half or three bushels an acre. The method broadcast, mostly above, but sometimes, if the land is got very fine, the seed is plowed under. If the harrow, in adjusting, leaves any clods unreduced on the surface, they are broken with the clotting beetle by women, &c. and if any twitch be pulled up in harrowing, it is shook out loose, with forks, and left on the surface to wither. The produce is generally extraordinary large, seven quarters an acre is no unusual crop; eight have been grown.

In his Rural Economy of Gloucestershire, he says, in the Cotswold hills the common long-eared barley is the only species, which is sown the latter end of March or beginning of April. The quantity of seed, three bushels an acre, produce generally from twenty bushels to four quarters an acre. In the vale of Gloucestershire it is made use of on every years lands as a clearing crop. It is harvested loose, mown with the naked scythe, lies in swath till the day of carrying, and is cocked with common hay-forks. The quantity of the vale barley is such as recommends it to the maltster, in preference to hill barley, that affords a more tightly sample. But there seems to be a quality in the soils of these vales which gives strength and richness to every article of their produce.

In his Rural Economy of Norfolk, he says the most prevailing and almost only species of barley sown in that district, is the common long-eared barley, for which the soil is peculiarly well adapted, and whose barley is coveted for seed throughout the kingdom. In the grand routine barley succeeds wheat and turneps, and in some very light land farms it is sown instead of wheat after the second year's lay after wheat; the stubble having been trampled down with bullocks at turneps, and wheat-seed being finished, the farmer begins to "scale in his wheat stubbles" for a winter fallow for barley. If the land lie in narrow work, the ridgelets are split; if in warps, the ground is likewise plowed clean, but very fleet. The beginning of March, the land is harrowed, and presently after the farmer "takes up his wheat stubbles" by a full-pitch cross-plowing;

or, if the season be wet and the soil heavy, he reverses the ridges. In April he harrows, and begins "stirring for barley," with another full-pitch plowing, lengthway; generally gathering the soil by this plowing, either into five-pace, or into ten-pace warps; in which it lies until seed-time, when it is harrowed, rolled, sown, plowed fleet, reversing the warps, and "sliding down" the furrows, so as to render the entire surface as even and level as may be.

After turneps, the soil is generally broken up as fast as the turneps are got off; if early in winter, by rice-balking; if late, by a plain plowing. The general practice, if time will permit, is to plow three times; the first fleet, the second full-pitch, the last a mean depth; with which last the seed is plowed in.

The Norfolk farmers, in general, are masters of the art of cultivating barley. They seem fully aware of the tenderness of this grain in its infant state; and of its rootlings being unable to make the proper progress in a compact or cold soil: they therefore strive by every means to render the soil open and-pulverous.

Nor is this caution confined to "turnep-barley," but is extended more or less to "stubble-barley;" which, however, does not require so great a degree of care; the soil in this case being kept open, in some measure, by the undigested stubble, and the roots of grasses and other weeds, which a turnep-fallow is or ought to be free from. Barley is seldom manured for, except when sown after lay, when it is treated as wheat. After turneps, no manure can be requisite; nor after wheat, if this has been manured for: if not, the turnep crop following immediately, the barley is left to take its chance; unless the opportunity be embraced for winter marling.

Notwithstanding the dryness of the Norfolk soil, barley may be said to be sown late in this district. There is little sown before the middle of April, and the seed-time seldom closes until towards the middle of May. The time of sowing, however, depends in some measure on the season; which, with respect to sowing barley, is more attended to in Norfolk than perhaps in all the world beside. Until Linnæus hit upon the idea of sowing by the foliation of trees, the republic of agriculture never heard of any other guide to the time of sowing than the almanack, which is still followed implicitly in every district in this kingdom, except Norfolk.

No instance either of fortifying it against disease, or of steeping it to forward its vegetation in a dry season, or a backward seed-time. This is strong evidence, though not a proof, that steeping seed-barley with intent to promote its vegetation, has no beneficial effect.

In this county, barley is all sown broadcast, and almost all under-furrow; that is, the surface having been smoothed by the harrow and roller, the seed is sown and plowed under with a shallow furrow: a circumstance this, which, until observed in Norfolk, had never occurred to many, either in practice or theory, though admirably adapted to a light dry soil; and, indeed, to any soil which is light enough to produce good barley; provided it be rendered sufficiently fine, and the seed be not buried too deep.

Barley, like wheat, is generally suffered to stand until it be very ripe. It is universally mown into swaths, with a small bow fixed at the heel of the scythe. Cradles are not in use; and the north country method of setting it up in singlets is unknown. Three bushels an acre may be taken as the nearest medium quantity of seed-barley. If barley receive wet in the swath, it is treated in a singular method in Norfolk. It is not turned, but "lifted:"—that is, the heads or ears are raised from the ground, either with a fork or the teeth of a rake; thereby admitting the air underneath the swath. This method of lifting is thought to stop the ears from vegetating nearly equal to that of turning, which requires more labour, besides breaking and ruffling the swaths, which, by repeated turnings, lose their stiffness, becoming weak and flabby, and liable to fall into close contact with the ground; in which state the corn presently begins to sprout.

Mr. Marshall, in his Rural Economy of Yorkshire, says that the long-eared barley and the big or four-rowed barley, generally called the winter-barley, are the species used in that county. The first in the vale when the season of sowing is driven very late. The winter barley is new to the district; and it does not seem to be yet generally understood that it ought to be sown in autumn.

One circumstance respecting the ancient husbandry of this crop deserves to be registered, as it serves to shew the alteration

alteration which time has the power of making, even in the business of husbandmen.

Less than a century ago, I believe, barley was not saleable until it was malted. Public malt-houses, and the business of a maltster were equally unknown: every farmer malted his own barley, or sold it to a neighbour who had a malt kiln.

Now, even public malt houses are unknown, the entire business of malting being in the hands of professional maltsters, who buy the barley of the farmer, and sell him the malt he may want for his own private use.

BARN, a covered place or house for laying up any sort of grain, hay, or straw.

Every farm should be furnished with barns proportioned to the quantity of corn it produces, which will be a great advantage to the farmer. The barns should have a dry situation, and be properly placed in the farm-yard, but not quite contiguous to the house, for fear of fire.

A barn is usually made of wooden frames covered with planks of oak, or built of brick or stone, which ever the country affords in the greater plenty; and in either case there should be such vent-holes, or openings, in its sides or walls, as to afford free admittance to the air, in order to prevent the mouldiness that would otherwise, from the least dampness lodge in the corn. The gable ends may be always of brick or stone, for the sake of greater solidity, and the whole may be roofed with thatch or tiles, as is most convenient. The size of the barn should be proportioned to the crop usually produced by the land to which it belongs. Two large folding doors should face each other, one in each side of the building, for the convenience of carrying in or out a waggon-load of corn in sheaves; and these doors should be of the same breadth with the threshing floor to afford the more light and air; the former for the threshers, and the latter for winnowing. Over the threshing floor, and a little above the reach of the flail, poles are often laid across from one beam to another, to form a kind of upper-floor, upon which the thresher may throw the straw or haulm, to make an immediate clearing, till he has time to stow it properly elsewhere: and on the outside, over the great doors, it will be right to form a large penthouse, made to project sufficiently to cover a load of corn, in case a sudden storm should come on before it can be housed; and also to shelter the poultry in the farm-yard, in great heat, or bad weather.

It is most advisable, and indeed most commonly practised in countries that abound in corn, to have a separate barn for wheat, another for spring-corn, such as barley and oats, and a third for peas, tares, lintels, clover, saint-foin, &c.

Some art, which must be the result of practice, is necessary in placing and piling up the sheaves in barns. But it may not be useless to observe, that it is always necessary to press them as close to the walls of the barn as possible, so as not to afford the least room for rats, or other vermin to creep in between them: for if they once get admittance they will soon penetrate further, lodge themselves in the mow, and do prodigious damage to the corn. Where this misfortune happens, the only remedy is to take down the mow, kill the vermin, and pile it up anew.

But the floor or threshing place, is the principal part of every barn, and therefore the greatest care ought to be taken in making it. In order to this, the surface of the intended threshing place is dug away to the depth of about six inches, and the earth thus taken out, after being well cleared of stones, is mixed with the strongest clay that can be procured, and with the dung of cows and oxen. This mixture is then worked together with water, till it is of the consistence of stiff mortar, and the compost thus made is spread as smooth as possible with a trowel, upon the spot from whence the earth was taken. As it cracks in drying, it must be beaten down with great force; or rolled with a heavy roller till all the crevices are filled up: and this must be continued till it is quite solid, hard, and firm.

The best barn-floor, both for threshing and for keeping corn, is that which is driest, smoothest, most completely solid, and consequently freest from cracks and holes, in which insects and vermin may shelter themselves, and even breed. The ancients were remarkably careful in this respect, as we learn from Cato, Varro, and Columella, the last of which excellent husbandmen relates particularly the great pains they took, first to dig up the ground to some depth, in order to moisten it with fresh lees of oil, but not with any that had salt in them; then to mix it thoroughly with chaff,

and ram it down as close as possible; afterwards as it dried, to stop all the cracks and crevices that appeared, to continue beating it down with great force, to render it quite level; and lastly, to strew it again with chaff, which they trod in, and then left it to be completely dried by the sun. All these writers agree, that the lees of oil, thus used, prevent the growth of weeds in these floors, and contribute to preserve the corn from being plundered by the mice and ants. Their barns were always seated high, and as dry as possible.

A floor made in the above manner must be greatly preferable to either stone, or the earthen floors, too common in many parts of England, and from which such dampness has been communicated to the corn, as has rendered wheat, for example, sixpence a bushel worse, either for keeping or exporting.

Boarded threshing-floors, made of sound, thick, well seasoned planks of oak, are excellent for service, will last a long time, and may be converted into good floorings for rooms, by planing them down, after they are become too uneven for the purpose originally intended.

Mr. Young, in his *Annals of Agriculture*, vol. XVI. gives two plans for the construction of barns; the first of which was sent him by his correspondent the reverend Mr. Roger Kedington, of Rougham in Norfolk; who says, "The mode of executing the work, I should recommend as follows: let the underpinning be of brick or stone, two feet high above ground, and let the sides be boarded: the roof of the barn will be best covered with reed or straw, and those of the stables with slate, or glazed tile; because they must be more flat, and the water which runs from the roof of the barn, would injure most other coverings. At each end of the barn, and over the back door, small doors four feet square, should be fixed, at the height of twelve feet from the ground; the two former for putting corn in at the ends, and the latter for filling the middle of the barn after the bays are full. All the bays should have a floor of clay or marl, and the threshing-floor be made with hard bricks, which will be sufficient for all sorts of grain, except wheat and rye; and for threshing them it will be good economy to have planks of oak or red deal, well fitted together and numbered, to be laid down occasionally, and confined by a frame at their ends. A barn built on such a plan would hold a great deal of corn, and be filled most conveniently: and if stacks of corn were built at each end, they might be taken in without any carting. If more buildings are requisite, two may be added on the backside like the stables in front; otherwise, if doors are made under the eaves on the backside, as directed at the ends, and stacks be placed opposite to them (just far enough to avoid the eaves dropping), by placing a waggon between them and the barn by way of a stage, those stacks may be taken in without carting; which method spares a great waste of corn and much trouble. The spars of the roofs of the stables rest upon the upper sills of the sides of the barn, and the outside wall of the stable is eight feet high; the barn supplying the highest side and one end of each stable; and the stables in return are buttresses to the barn, and strengthen it greatly.

A barn built of the dimensions of the inclosed plan, with two stables, might, in this country, be built for the following sum. The underpinning of the barn, three feet and a half high from the foundation, and a brick and half thick, will contain six hundred and fifty-two feet of brick work nearly. The underpinning of the stables, one brick thick and three feet high from the foundation, will contain one hundred and forty-four feet, the whole amounting nearly to three rods of brick work; which, at 8l. per rod, amount to 24l. The threshing floor contains fifty-six yards; and may be paved with hard white bricks, laid edge-ways, for 8l. 8s. It will be proper to make an underpinning on each side of the threshing-floor two feet in depth and one brick thick, to prevent vermin from burrowing under it; and this, added to the underpinnings first mentioned, will not exceed three rods of brick-work; so the total expence of the threshing floor and the underpinning will be 32l. 8s. The frame of the barn, with two stables complete (allowing the beams, posts, sills, studs, and principal spars to be of oak, and the sides to be covered with featheredge boards, of red-wood deal), would cost 200l.; and 50l. more would be required for the reed and slating of the roofs. The iron work for hinges, cramps, nails, &c. would amount to another 10l. and a small additional expence would be highly proper for paint, or some cheaper composition, to preserve all the wood,

that

that is exposed to the weather. The workmanship is included in the whole of the above estimate, which you may observe is altogether very near 300l. See Plate II*.

Mr. Young has given a plan for another barn as follows :

"The mere ideas of theory in making propositions to assist others (even the youngest of beginners) I have a very poor opinion of, and I would not venture to recommend the idea I have of a good barn to the reader's eye, if I had not for some time experienced the great convenience resulting from this arrangement ; it is true, that my barn having been built many years, and in some respects very awkwardly placed, I had it not in my power to convert it into such a regular design as is in the power of those who build all new ; but I have in my additions all the circumstances of the sheds and their connection with the barn as here represented.

To arrange buildings of this nature conveniently is of prodigious importance to cattle, sheep, and hogs ; and also to saving expences in labour and in waste of hay, straw, &c.

It is proper to note, respecting the size of this barn, that the plan was sketched in consequence of a request from general Washington, that I would send him my idea of a good barn, and the necessary adjuncts, proportioned to a farm of 500 acres. The threshing floor of this barn is large enough for three men to work in, who can in a winter thresh corn of such a farm ; and all summer threshing is to be condemned when from any other motive than that of having straw for litter.

The new invented machines for threshing would alter very much the plan of a barn ; where they are used, they should be built in the center, and the corn stacks so disposed around as to supply the machine without the use of cart or horse : than which nothing is more easy to contrive. The barn in such case is a mere receptacle for straw, and should be contrived with a view to its distribution.

I have seen very expensive barns in Ireland, which the owners have boasted would confine a mouse ;—so much the worse : there cannot be too much air all around : the sides, for this reason, should be neither of brick nor stone, unless (which would be very difficult) the whole was a system of arches for being perfectly pierced with apertures of the form of a small segment of a large circle : tunnel brick, which I have seen let into the walls, are always far too few to do good, and the common air holes are nothing. The best barns (for corn) are of boards ; and the more air those boards admit, the better will the straw be for the cattle ; and the brighter the sample of corn in a ticklish season.

Combine this fact with Hendon farmers, where the best hay perhaps in England is made, never putting it in any sort of building, always in stacks.

It will be remarked, that there is no provision for water ; I am much in doubt whether there ought to be, fattening cattle on dry food alone excepted. But for all young cattle, of whatever age, cows, &c. I much prefer their being unchained twice a day and walked or led to the mouth of a neighbouring pond ; the reason is, the cattle are by this means brought up in habits of being constantly gentle and quiet ; and not apt to be frightened or skittish when put to fattening or the dairy, which is an object of much more consequence than the value of the labour. Water conducted in pipes or troughs freezes during much of the winter, and is then a nuisance ; and for all beasts on turneps or cabbages none is wanting. The expence also of making these conduits is a very great addition to the building ; and the labour of pumping not to be forgotten.

In this opinion I go against the Herefordshire vaunted practice ; but their system does not at all meet my ideas ; and the expence of giving every bullock room enough to turn around to go and drink adds so greatly to the extent of building as puts it out of the question for any persons but gentlemen on their own farms.

No notice is here taken of a hogger, which is an important object ; but I am apt to think, after much experience (for I once built a most complete one, the plan of which I have inserted in this work), and much reflection since, that it should be in a distant part of the farm, the carriage of food, more especially for fattening, is nothing to that of dung ; and having all the dung of a farm of 300 to 500 acres accumulated at one place (very rarely the centre) is a most expensive circumstance. In a large, or in a breeding system, a small cottage for a trusty servant must be added, to watch sows and pigs, but the expence would not be large.

The same observation is applicable to a standing sheep

fold or yard ; in this case it is essential that the shepherd's dwelling should be close, and even looking into it, but not the door opening into it. The way should be circuitous, to keep women and children from disturbing the flock.

All these points must vary according to peculiar views or circumstances of a farmer and his farm, and even neighbourhood : but they are very important and much deserve attentive consideration.

EXPLANATION. 1, 2, 3, 4, 5, 6. The barn.

1, 2, 7, 8. The porch of ditto with a small door, at 9, 10, 11. The great door in at which the carts enter with corn.

12. The threshing floor which extends the space of 1, 2, 10, 11.

13, 13. Bays, in which the corn is stowed.

14, 14, 14, 14. Sheds, for cattle, oxen, and horses.

15, 15, 15, 15. Mangers, two feet broad, out of which the cattle eat their straw and chaff, and turneps, carrots, cabbages, potatoes, &c.

16, 16, 16, 16. Passages, between two and three feet wide, for carrying straw from the threshing floor to feed the cattle.

17, 17, 17, 17. Doors into the passage.

18, 18, 18, 18. Principal posts on which the sheds rest.

19, 19, 19. Gutters for conveying the urine of the cattle to.

20, 20. Cisterns, out of which it is every day thrown on to dunghills, placed regularly within reach.

From the mangers 15 to the gutters 19, there is a pavement of bricks upon a slope, so laid as to finish six inches perpendicular above the gutter, and which pavement is six feet broad from that edge to the manger. The gutters are from 18 to 20 inches broad.

21, 21, 21, 21. Are sheds for various uses. If a dairy is kept, and one or two of the sheds, 14, appropriated to cows, one of these sheds will do for calves, also for chaff, turneps, roots, &c. in case of frosts, &c.

22, 22. Two yards each, with a shed for shelter, to be applied to any purpose wanted ; one for sheep, surrounded with low racks, and the other divided for a horse or two loose, if wanted ; the other half for yearling calves, which do better in a farm-yard than stalled.

23, 23. Inclosure of walling or pales.

If one of the yards be applied for hogs, then one of the sheds, 21, will be useful for their appurtenances.

1, 2, 8, 3, 4, 5, 6, 7. The main body of the barn which rises 14, 16, or 20 feet to the eaves.

All the rest are sheds placed against it, being the cheapest way of covering cattle that has yet been discovered.

I should add, that I have this general idea executed in my own farm, though not so complete as here sketched, because not built at once, and that I find it perfectly convenient.

Should the quantity of cattle to be kept be greater than here admitted, a circular shed should be erected fronting the door 9, and the hay stacks must be disposed conveniently near those sheds appropriated for cows, horses, or fat cattle. Corn stacks must be built on the contrary side of the barn if other circumstances allow.

Mr. Marshall, in his Rural Economy of Norfolk, says, the barns of Norfolk are superior to those of every other county ; numerous and spacious. No farm has less than three threshing-floors ; some farms five or six, and these of unusual dimensions. Twenty-four feet by eighteen is considered as a well-sized floor ; twenty by fifteen, a small one. Indeed, a floor of less dimensions is ill adapted to the Norfolk method of cleaning corn ; which is universally effected by casting it with shovels from one end of the floor to the other. To obtain this necessary length of floor, a porch, on one or both sides of the barn, is almost universal. A lean-to porch, with double doors to let out an empty waggon, and with a range of lean-to sheds or hovels on either side, continuing the roof of the barn, without a break to the eaves of the porch and sheds, is at present, deservedly, in good estimation.

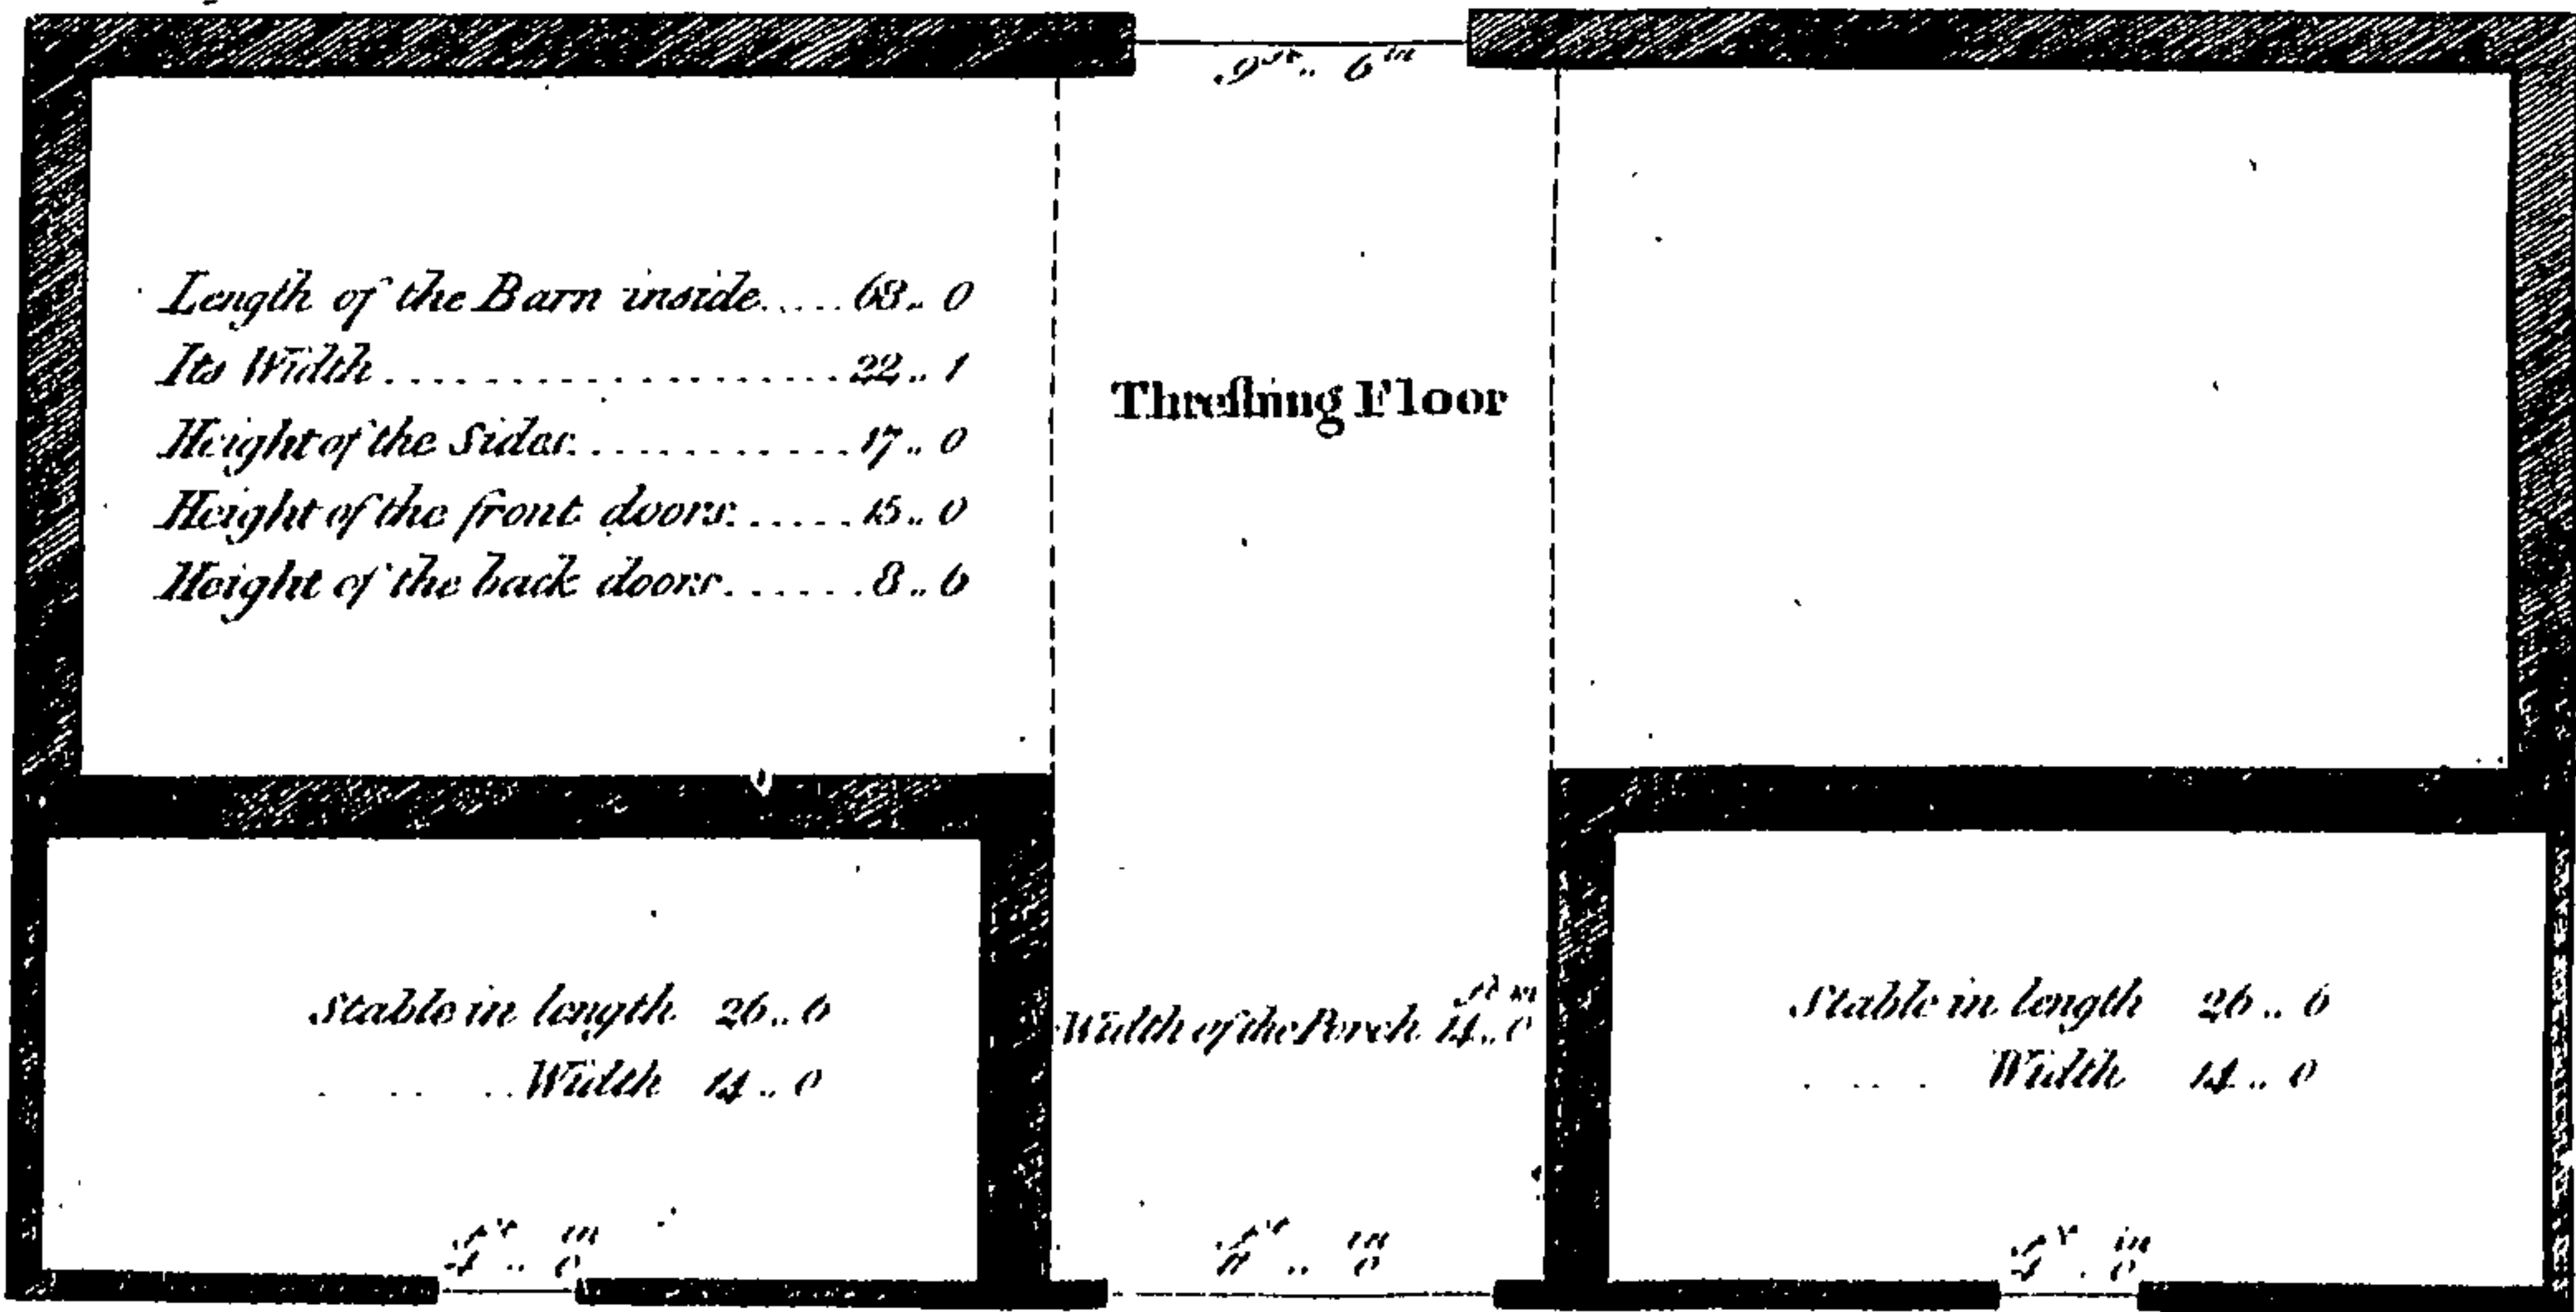

Barn-floors are of plank, "lumps" (a kind of bricks), or clay : the last are most prevalent ; and although they be considered as inferior to the first, they are in better esteem in Norfolk than in most other places.

It is observable, that notwithstanding the spaciousness of the Norfolk barn-floor, the labourers in general object to their threshing two in a barn : rather choosing to work singly :—this, perhaps, is principally owing to the particular method of threshing with two on a floor ; which is, to turn their backs on each other ; working as separately as if they

PLAN of a BARN and CATTLE-SHEDS.

A BARN and STABLES

they threshed on separate floors: the method of standing face to face, and giving stroke for stroke, being seldom if ever used.

In his Rural Economy of the Midland Counties, he says, "The only thing noticeable in the barn of this district, is an improvement, lately introduced I believe, in the means of supporting the roof. Instead of beams and principals, partial partition walls are raised, on either side the floor and between the bays, to take the purlines; leaving an opening, or large doorway, in the middle of the building, to admit the corn.

In a capital barn where two pair of purlines were necessary, the cheeks of walling are narrow; not more than five feet wide; receiving the lower purlines only; with short beams and principals, resting on the tops of the cheeks or partial partition walls, to support the upper ones.

This mode of construction is cheaper than oak beams; takes the weight of the roof in a great measure off the side walls; and frees the body of the barn from beams (well known nuisances in filling a barn); yet stiffens the building. On each side the floor, these partial partitions are evidently eligible, on these and various other accounts; without any evident disadvantage.

Barn floors. In this district, a peculiar method of laying wooden barn floors is in practice. Instead of the planks being nailed down to sleepers, in the ordinary way, the floor is first laid with bricks, and the planks spread over these, with no other confinement than that of being "dowled" together (that is ploughed and tongued) and their ends let into fills or walls, placed in the usual way, on each side the floor.

By this method of putting down the planks; provided the brickwork be left truly level; vermin cannot have a hiding place beneath them; and a communication of damp air being effectually prevented, floors thus laid are found to wear better, than those laid upon sleepers. It is observable, that the planks, for this method of laying, ought to be thoroughly seasoned.

The same author, in his Rural Economy of Yorkshire, says, "I observed here an entire farmery under one roof. One end occupied a small dwelling, the ground floor of the remainder by a stable and beast-house; over which are a barn and hay-chamber; with a chamber-barn-floor: a thing I had not seen, nor conceived an idea of, before I observed it, in more instances than one, in this district.

The above-mentioned is the only one I have seen in a new erection: I have however had full opportunity of observing the use of another thrown over a cow-house; in a large old building which had long been used as a barn, stable, and beast-house.

The advantages of a chamber-barn-floor are dryness, cleanness from dirt carried in with the feet, and security against pigs, poultry, and other accidents to which ground-floors are more liable: for threshing wheat upon, chamber-floors are obviously preferable to ground-floors; most especially in low dirty situations.

No essential disadvantage has yet struck me respecting a chamber-threshing floor; but with respect to a chamber-barn, there is one which is obvious; namely, that of having the corn at harvest, a busy season, to raise one story higher than ordinary.

Another idea in rural architecture, new to me as that of a chamber-threshing-floor, I have seen executed in a substantial manner by two of the first occupiers in the vale; namely, a granary over a barn-floor.

In all other barns I have seen, the space over the floor, whether this be large or small, and whether the building be low or lofty, remains entirely useless except in one instance, in which a very spacious building having been converted into a barn, joists were thrown across out of the reach of the flail, and the mows continued over the floor. The idea of occupying the lower part of this space with a cattle-house, as well as that of filling the upper part of it with a granary, have perhaps been originally and recently struck out in this country.

In the two instances in which I have seen granaries over barn-floors, the joists are supported by two beams thrown across the building, and the flooring of the granary let into the walls at the ends; so that notwithstanding the granaries may be surrounded with vermin, they are proof against them.

In the floor is a trap-door with tackle over it, to raise and lower the corn from and to the barn-floor.

The height between the floors thirteen feet. This in

my opinion is too great a height. Ten feet high is the most the flail requires; and every inch above that height renders the granary in many respects less commodious.

Confining the dust, which always rises more or less in threshing, appears to be the only objection to a barn-floor-granary: I mean in a barn with pitching-holes to house the corn at. But if ventilators were made immediately under the granary-floor, with valves to open or shut as the wind should change, the health of the thresher would in all probability be less injured than it generally is by this laborious and unhealthful employment.

Indeed, in this country, where tall, wide folding barn-doors are grown into disuse, vent-holes of this kind are in some degrees necessary to every barn-floor. Even upon the Wolds, a corn country, the use of large doors is declining: some good barns have lately been built with common-sized doors; one at each end of the floor: opening however in two parts, one above the other; so that the lower half can be shut to keep out pigs and poultry, while the upper one is opened to let in light and air.

This is a fortunate circumstance for the owners of landed estates: folding-doors large enough to admit a load of corn are expensive in the first instance, and frequently require repairs; besides the threshing-floor, be it of what material it may, being liable to great injury in the act of drawing loaded waggons upon it.

Indeed, throughout, the Yorkshire-barn is characterised by economy. In Norfolk, barns of one hundred and fifty to two hundred pounds cost are not unfrequently built: here a very convenient one, and such a one as will satisfy a good tenant, may be built for forty or fifty pounds. What a saving is this upon a large estate!

In his Rural Economy of Gloucestershire, he observes that in that county, he also met with a granary over a barn-floor: the height about ten feet (just out of the reach of the flail); and with two instances of granaries over pitch-roof porches; a new idea, and a very good one. The corn is hoisted up by tackle; and shot down through canvas tunnels into bags placed below.

"The size of barns, in this country, is above par. In height, above any I have observed. Fifty-two by twenty feet in the clear, and sixteen to twenty feet high to the plate, is esteemed a good barn. This size admits of four bays of ten feet each, with a floor in the middle. Three are some remains of old monastery barns, of great size, in this district.—The height of modern barns may have arisen from observing in those that "one foot below the beams is worth two above."

Barn-floors are of a good size: 12 to 14 by 18 to 20 feet. The best of oak: some of stone: but a species of earthen floor which is made, here, is thought to be superior to floors of stone, or any other material, except sound oak plank. The superior excellency of these floors is owing in part to the materials of which they are made; and in part to the method of making.

BARNACLES, horse-twitchers, or brakes, are a sort of instruments used by farriers to put upon horses noses, when they will not stand quietly, to be shod, blooded, or dressed.

There are several sorts of barnacles, the common sort are rollers of wood bound together, to hold the horse's nose between. Another sort have handles, and are therefore termed pincers, to distinguish them from the foregoing. And a third sort are held together at the top by a ring inclosing buttons, having the top buttons held by an iron pin rivetting through them.

BARREN CORN, a name given to a distemper in corn, by M. Aimen, who first observed it. The ears of wheat or rye, the species most subject to this distemper, which are thus affected, are long, lean, and white; in some the stamina, or small threads in the middle of the flower, are dry, transparent and horned; the female organs are small, whiter, and less velvety, than in healthy ears: in others, the filaments are swelled, the apices, or knobs on the tops of the stamina, void of dust or farina, and the stigmata badly unfolded. The stigmata of all the blossoms of an ear are sometimes dried and parched; at other times the apices are swelled.

BARREN EARTH, a name given by some to the under stratum of earth, or that which lies below the stratum frequently turned up, and cultivated for the nourishment of plants.

This notion of the under stratum of earth being dead or barren, and will destroy every vegetable planted in it, seems to be founded on a mistake: for every kind of earth, whether it be upon or under the surface, is certainly capable of

giving nourishment to plants, provided it be for some time exposed to the influence of the air, frosts, &c. in order to enable it to dispense its nutritive qualities. An earth seemingly barren dug out of a deep pit, will, if spread on the surface, and properly stirred and exposed, be soon in a condition of bearing plants, and even much more so than the earth, which having been long at the surface is almost exhausted, by the number of vegetables it has successively nourished. The notion of any earth being barren, merely because it is placed at a distance from the surface, is by the most intelligent naturalists exploded; its particles may perhaps want a proper arrangement, but it always possesses the vegetative quality. This opinion has been confirmed by repeated experiments; and a very remarkable one of this kind is related by a correspondent of the editors of the *Museum Rusticum*, vol. I. p. 100, &c. where the writer tells us that he planted a quantity of potatoes in a piece of what they called dead barren earth, the upper bed having been taken away and spread on the adjacent land. Yet in this spot of ground dug two spits deep by the help of spades and mattocks, and the earth broke as fine as possible, he had a prodigious crop of remarkable fine potatoes; though the earth had not been exposed to the influence of the atmosphere above two months, it being dug in February, and the potatoes planted the latter end of March.

BARREN SPRINGS, a name given by husbandmen to such springs whose waters are injurious to land.

Most waters that flow from coal-mines, or through beds of sulphureous minerals, have this pernicious quality, destroying vegetables, instead of nourishing them. They have a harsh and brackish taste, are generally of a reddish colour, and deposit a reddish sediment in the channel through which they flow. They are much better when they have run some distance, than at their first breaking out on the surface of the earth. *Mortimer's Husbandry*, vol. I. p. 20.

BARBS, the fleshy rows that run across a horse's mouth, reaching almost to the palate. They are very distinguishable in young horses.

BARTH, a warm place, or pasture for calves and lambs.

BARTON, or **BARKEN**, the yard of a house.

BASTARD *Alkanet*, called also *bastard gromill*, or *sal-farn*, a weed common among corn, especially rye. It may be easily known by its red roots, which yield a red tincture, and are used by the young girls in Sweden to colour their cheeks. From the root usually rises a single stem about a foot high, rough and branching out at the top. The flowers are small and white, surrounded with five long, narrow, hairy leaves, forming what the botanists call the empalement of the flower cup, and succeeded by four white rough seeds. See the figure of this plant on Plate III fig 2.

BAVINS, brush-faggots, or faggots made with the brush-wood at length.

BAUSON, the same with badger. See **BADGER**.

BAY, a colour in horses, so called from its resembling the colour of a dried bay-leaf.

There are various degrees of this colour from the lightest bay to the dark, which approaches nearly to the brown, but is always more gay and shining. The bright bay is an exceeding beautiful colour, because a bright bay horse has generally a reddish dash, with a gilded aspect, his main and tail black, with a black or dark list down his back. The middle colours of bay have also frequently the black list, with black main and tail. And the dark bays have almost always their knees and pasterns black; and we meet with several sorts of bays, that have their whole limbs black from their knees and hocks downwards. The bays that have no list on their backs, are, for the most part, black over their reins, which goes off by an imperceptible gradation from dark to light towards the belly and flanks. Some of these incline to a brown, and are more or less dappled. The bay is one of the best colours, and horses of all the different kinds of bays are commonly good, unless when accidents happen to spoil them while they are colts. *Gibson on Horses*, vol. I. p. 44.

BAY of a barn, that part where the mow is placed. Hence such barns as have the threshing floor in the middle, and a space for a mow on each side, are called barns of two bays, &c.

BAYARD, a bay horse.

BEANS, a sort of pulse well known, and of which there are two species, distinguished by the name of the garden-bean, and the horse-bean.

Some few trials have been lately made in France to raise

garden beans in open fields, on the principles of the new husbandry: and the result of these experiments sufficiently indicated that very large crops may be procured by that method if properly practised. M. du Hamel tells us, that M. Eyma planted, in December 1755, in a field near Bourdeaux, the common sort of garden beans, in a middling soil not dunged, but thoroughly ploughed a foot deep. The rows were two feet asunder, and the plants a foot distant from one another. These beans, which every one thought too thinly sown, being assisted by frequent hoeings, yielded a greater crop than any in the common way. When they began to ripen, M. Eyma gave the spaces between them a good plowing, and on the twenty-third of June sowed in each of them a row of red kidney beans, which came up very well. In a fortnight after he plucked up the garden beans, and gave the ground on which they stood a slight hoeing. These kidney-beans proved the finest he ever saw. He repeated the same experiment in 1756, and was rewarded with such success as surpassed his warmest expectations. *Traité de la Culture des Terres*, tom. V. p. 81.

Purple BEANS, a kind originally brought from the Cape of Good Hope, had an experiment made on their prolificness in January 1775 by Mr. Marshall, who had made it a piece of parlour furniture since the preceding harvest. It had, when drawn, upwards of ninety pods, but some of them immature.

	2 of the pods had	5 each	10 beans.
12	- - -	4 - -	48
37	- - -	3 - -	111
27	- - -	2 - -	54
7	- - -	1 - -	1
85 pods.			230 vegetative beans.

He put the fives and fours in a paper by themselves; as he did the threes in a second paper; and the twos and ones in a third paper, to try whether the seed which springs from the root was specially fructuous, or was not, in itself peculiarly prolific, and whether the particular circumstances of its production influenced its produce. In July, 1777, these beans were drilled indiscriminately, in a patch of the same species; when the particular produce of the pods of different sizes were identified by labelled stumps, and the experiments rigidly attended to: but at harvest not the smallest disparity could be discovered; for the bean brought forth singly was equally prolific with that brought forth in a pod of 4 or 5.

Mr. Marshall recommends the pulling beans, for he says the benefit the soil receives will more than pay for the extra labour in clearing. Indeed they were liable to have lumps of dirt to adhere too large to be sifted out, and too heavy to be blown out, nor did casting them from one end of the barn floor to the other with a shovel remove it; but after several experiments, he put about half a bushel into a sack and threshed them for a few seconds; they were then shook in a wheat-riddle, and came out perfectly clean. The flail breaks the clods, and the wheat-riddle lets the dust and small refuse beans through it. In another experiment he approves of their being trod by a man as more expeditious. Another advantage arises from their being pulled, is, the stubbornness of the roots keeps the mow open, and admits a circulation of air. The quantity to be put into the sack to be trod out should be about two bushels in a four bushel sack, and the expence about 7d. or 8d. a quarter. The same gentleman says in another place, that by experience he found that by pulling up by hand, is far preferable to cutting with sickles: they may be pulled up faster and much cleaner from weeds and grass than when cut, besides leaving the land in a state greatly superior. The waste is less, as to lose scarcely a bean; and the bean stalks are immediately ready to bind and set up; and by the roots lifting the earth from the ground, gives the air a free circulation. The work is also easier to the labourer, who stands more upright, and the power required is much less, especially in dry weather. By striking the roots of each handful against the foot, the mould is almost wholly disengaged from the fibres. The soil in the drills, instead of being bound by the roots, and cumbered by the stubble, is left as loose as a garden, and the surface free from obstructions; and if thoroughly hoed is as fit as a fallow to be sowed with wheat on one plowing.

Horse BEANS, delight in a strong moist soil, and an open exposure, for they never thrive well on dry warm land, or in small inclosures, where they must, and are frequently

attacked by the black dolphin fly: these insects are often in such quantities as to cover the stems of the beans entirely; especially all the upper part of them; and whenever this happens, the beans seldom come to good; but in open fields where the soil is strong, and the plants have room, this rarely happens.

These beans are usually sown in land which is fresh broken up, because they are of use to break and pulverise the ground, as also to destroy weeds; so that the land is rendered much better for corn, after a crop of beans, than it would have been before, especially if they are sown and managed according to the new husbandry, with a drill plough, and the horse-hoe used to stir the ground between the rows of beans; which will prevent the growth of weeds, and pulverise the ground, whereby a much greater crop of beans may, with more certainty, be expected; and the land will be better prepared for whatever crop it is designed for after.

The season for sowing beans is from the middle of February to the end of March, according to the nature of the soil; the strongest wet soil should always be last sown. The usual quantity of beans sown on an acre of land, is about three bushels, though this is double the quantity that need be sown, especially according to the new husbandry; but it will be necessary first to set down the practice according to the old husbandry, and then give directions for their management according to the new. The method of sowing is after the plough, in the bottom of the furrows; but then the furrows should not be more than five, or at most more than six inches deep. If the land be newly broken up, it is usual to plough it early in the autumn, and let it lie in ridges till after Christmas, then to plow it in small furrows, and lay the ground very smooth. These two ploughings will break the ground fine enough for beans, and the third ploughing is to sow the beans, when the furrows should be made shallow, as before mentioned.

Most people set their beans too close; for as some lay the beans in the furrows after the plough, and others lay them before the plough, and plough them in; so by both methods the beans are as close as the furrows are made, which is much too near: for when they are on strong good land, they are generally drawn up to a very great height, and are not so apt to pod as when they have more room, and are of a lower growth. The better way, therefore, is to make the furrows three feet asunder or more, which will cause them to branch out into many stalks, and bear in greater plenty than when they are closer; by this method less than half the quantity of beans will be sufficient for an acre of land, and the air being admitted between the rows, the beans will ripen much earlier, and more equally than in the common way. *Miller's Gard. Diet.*

It has been already observed, that the black dolphin fly often destroys a crop of beans, and to prevent which a correspondent of the editors of the *Museum Rusticum* proposes, that when these destructive insects are first seen on the tops of the beans, one or more persons, provided each with a scymetar or hanger, should be sent in the field, and strike off the heads of the beans. He adds, that by this means a crop has been often saved, this fly being seldom known to rise again when it once falls with the bean top to the ground. *Museum Rusticum*, vol. III. p. 233.

Another correspondent in the above work says, that as soon as the beans have got six leaves, the sheep should be turned in to feed among them; for they will eat up all the young weeds, even the melilot, without touching the beans. He adds, that the sheep may be kept every day among the beans till they are in blossom; but they must not be suffered to lie down. *Museum Rusticum*, vol. III. p. 339.

When beans are intended to be planted according to the new husbandry, the ground should be four times ploughed before the beans are set, which will break the clods, and render it much better for planting. Then use a drill plough, to which a hopper is fixed for setting the beans, the drills should be made at three feet asunder, and the spring of the hopper set so as to scatter the beans at three inches distance in the drills. By this method less than one bushel of seed will plant an acre of land. When the beans are up, if the ground be stirred between the rows with a horse-plough, it will destroy all the young weeds; and when the beans are advanced about three or four inches high, the ground should be again ploughed between the rows, and the earth laid up to the beans; and if a third ploughing, about five or six weeks after be given, the ground will be kept clear from weeds, and the beans will stalk out, and

produce a much greater crop than in the common way. *Miller's Gard. Diet.*

A correspondent of the editors of the *Museum Rusticum*, has given the following method of cultivating beans in the vale of Aylesbury.

"First, says he, I plough two furrows on each outside of the land, but sow no beans in them: I afterwards drill, with an instrument hereafter described, the three next furrows: then I plough two furrows without drilling any beans in them, and so on, sowing three, and leaving two for intervals, till the land is finished.

"When the beans are about two or three inches high, I plough two furrows up each interval, turning the furrows from the beans, so as to make a ridge in the middle of each interval. I have a little plough on purpose for this use; about half the size of a common plough, which is drawn by one horse.

"This work should be done after a rain. This year, 1764, on the fifteenth of May we had rain. I therefore went to plough in the intervals on the eighteenth, and continued at plough till all were finished. On the eighth of June we had rain again. On the ninth of June I went to harrow the intervals with the triangular harrow hereafter described. About a week after that we had more rain. I then went to harrow again, going up the interval I went down before; and down that which I went up. This is what we call cross-tining. Thus my land is laid quite smooth, kept clear from weeds, and the beans have a fine loose mould to strike their fibres into; and it is by far the cheapest way of weeding beans.

Proportions of the above DRILL (see Plate III. fig. 3.)

"Diameter of the iron wheel twenty inches.

"Length of the box from A to B, twenty inches.

"Breadth of the box from B to C, ten inches.

"Depth of the box from C to D, five inches and a half.

"Diameter of the cylinder of wood upon the iron axis of the wheel, four inches. This cylinder turns out the beans regularly.

"Length of the cylinder two inches and a half. On this cylinder are twenty-one holes, a quarter of an inch deep, and half an inch in diameter.

"E is a tongue, which drops upon the cylinder, and plays up easily: the tongue is half an inch thick, and three quarters wide. When a larger bean than ordinary comes, it will throw the tongue up, which naturally recovers its place again; and so the work goes on well and even. The tongue is represented separately with its notch at E: the notch does not go quite through it; it falls exactly on the holes of the cylinder.

"A lid takes off to put the beans into the box; and buttons down at F."

The triangular HARROW described (see Plate III. fig. 4.)

"From A to B eighteen inches.

"The tines are nine inches a-part.

"The three tines in the cross-bar are only three inches and a half a-part.

"E, a cock which plays upon a pin; in which are three holes to hang the whipple tree in. If you put it into the upper hole, the tines bear very heavy upon the ground; I generally use the middle hole." *Museum Rusticum*, vol. III. p. 26.

When the beans are ripe they are reaped with a hook, as is generally practised for pease; and after having lain a few days on the ground, they are turned, and this must be repeated for several times, until they are dry enough to stack; but the best method is to tie them in small bundles, and set them upright; for then they will not be in so much danger to suffer by wet, as when they lie on the ground; and they will be more handy to carry and stack, than if they were loose.

The common produce is from twenty to twenty-five bushels on an acre of land. *Miller's Gard. Diet.*

In the stiff, strong land, of the vale of Aylesbury, they annually sow a great many acres of horse-beans, all which they usually mow with a bare scythe, in swarth, as they call it; that is they mow beans towards the beans; and each mower has a boy, who follows him with a fork, and lays the beans in wads. Their reason for mowing them in swarth, is on account of the largeness of their crops, and the beans leaning inwards; it is only when they have a thin crop,

crop, that they venture to mow them against their bending (this they call throatings;) for should they do it in common, it would break the hearts of the mowers, being as hard work again as the other.

When they mow in swarth, the workmen always keep the points of their scythes downwards, or they would strip off great quantities of the beans.

In Hertfordshire also, some farmers mow their beans with a scythe, and a three ribbed strong cradle: this cuts a great deal in a day, lays the beans in regular rows, and saves the expence of a wadder; but in Buckinghamshire they cannot use a cradle, their crops being in general so heavy, that the workman could not carry over the swarth. *Museum Rusticum*, vol. I. p. 275.

The beans should lie in the mow to sweat, before they are threshed out; for as the haulm is very large, and succulent, so it is very apt to give and grow moist; but there is no danger of the beans receiving damage, if they are stacked tolerably dry; because the pods will preserve the beans from injury; and they will be much easier to thresh after they have sweat in the mow than before; and after they have once sweated and are dry again, they never after give.

By the new husbandry the produce has exceeded that of the old by more than ten bushels an acre; for if the beans cultivated in the common method are observed when they are in pod, it will be found that more than half way of their stems have no beans on them; for by standing close, they are drawn up very tall, so the tops of the stalks only produce, and all the lower part is naked; whereas in the new method, they bear almost to the ground; and as the joints of the stems are shorter, so the beans grow closer together. *Miller's Gard. Dict.*

Beans are a part of the diet of horses, but chiefly used in mixture with bran or chaff, and by some upon the road, with oats; but they are mostly given to coach horses and others that are constantly in draught. They afford the strongest nourishment of all other grain, and will enable horses to go through a great deal of heavy labour; but in some seasons they breed a kind of vermin, which the farmers call a red bug, and is reckoned dangerous, and therefore the best way at such times is to have them well dried and split, which may, in some measure, destroy the quality that is engendered in them. *Gibson on Horses*, vol. I. p. 171.

Mr. Marshall, in his Minutes of Agriculture, recommends the rolling of both peas and beans as a good preparative to hoeing; at a time when they open a broad leaf, and lay flat on the ground; Indeed he trampled on them and rubbed some of the plants hard with his foot, and at the expiration of a week they had not the appearance of having received any injury; and he says that beans when their broad leaves lie flat on the ground may be harrowed and rolled with safety.

Mr. Young, in the 2nd. vol. of his Annals of Agriculture, observes that the May beans are not subject to the grub as others are, and they are by much the best bearers. In another part of that valuable work in vol. VII. he experienced the great benefit of bean straw in feeding lean cattle.

In the 5th vol. of the memoirs of the Bath society of agriculture, page 39 is the following paragraph:

"I have found, by repeated experience that beans are a much more hearty and profitable food for horses than oats. Being out of old oats the two last springs, I substituted horse beans in their stead. In the room of a sack of oats with chaff, I ordered them a bushel of beans with chaff to serve the same time. It very soon appeared the beans were superior to the oats from the life, spirit, and sleekness of the horses.

Whoever has frequented the corn markets in London cannot but know that old horse-beans sell from ten to fifteen, and even more, per cent. dearer than new corn: because new beans will, by their abundant crudity, give a horse the gripes, and other disorders equally fatal. To prevent such consequences, and at the same time save the difference between the expence of old and new corn, a correspondent of the editors of the *Museum Rusticum* tells us that he made the following experiment.

He purchased a quantity of new beans, and filled a large tub with them, pumping in as much water as was necessary to wet them: after soaking about ten hours he drew off the water, and laid the beans in a heap on the floor. In this manner he suffered them to continue till they began to heat, when he spread them out thinner, moving them often with a malt shovel, and letting them lie in beds till the germ

swelled and became turgid. Then he carried them to a malt-kiln, and dried them gradually; and gave part of them to his horses, as soon as cold.

By this preparation he assures us new beans will agree as well with cattle as any old corn that can be procured at the market.

The greatest nicety in the operation is to prevent the beans from sprouting, or malting, which would injure them, and not to dry them by too quick a heat. *Museum Rusticum*, vol. I. p. 327.

BEAR, or *berc*, a species of barley, called also winter barley, square barley, and big.

This grain is chiefly cultivated in Scotland, the northern parts of England, and Ireland. It yields a very large return, but is not esteemed so good for malting as the common barley, for which reason it is very little cultivated in the southern parts of England. See BARLEY.

BEARD, the same with awn. See AWNS.

BEARD of a horse, a name given to the hairs scattered on his under lip to the place where the curb of the bridle rests.

BEARDED oat grass, the same with wild oats. See the article WILD OATS.

BEASTS of BURTHEN. See OXEN, and HORSES.

BEDS, a name given by many writers on the new husbandry to the spaces occupied by the rows of corn; to distinguish them from the intervals, or open spaces between these beds, which they term alleys. See ALLEY.

Yellow ladies BEDSTRAW, *cheefe-rennet*, *maid's hair*, or *petty mugwort*, a weed very common in moist meadows and pasture grounds. Its slender stalks rise to about a foot in height. The leaves come out in whorls, eight or nine together. They are long, narrow, and of a green colour. Two little branches generally come out near the top of the stalk, supporting a considerable number of small yellow flowers, consisting of one petal, divided into four parts, and succeeded by two large kidney-shaped seeds.

BEE, a small and well known insect, famous for its industry.

This useful and laborious insect is divided by two ligaments into three parts or portions, the head, the breast, and the belly. The head is armed with two jaws and a trunk; the former of which play like two jaws opening and shutting to the right and left. The trunk is long and taper, and, at the same time, extremely pliant and flexible, being destined by nature for the insect to probe to the bottom of the flowers through all the impediments of their chives and foliage; and drain them of their treasured sweets: but were this trunk to be always extended, it would prove inconvenient, and be liable to be injured by a thousand accidents, it is therefore of such a structure, that, after the performance of its necessary functions, it may be contracted, or rather folded up; and besides this, it is fortified against all injuries by four strong scales, two of which closely sheathe it, and the two others, whose cavities and dimensions are larger, encompass the whole. From the middle part or breast of the bee grow the legs, which are six in number: and at the extremity of the paws are two little hooks, discernible by the microscope, which appear like sickles, with their points opposite to each other. The wings are four, two greater and two smaller, which not only serve to transport them through the air, but, by the noise they make, to give notice of their departure and arrival, and to animate them mutually to their several labours. The hairs with which the whole body is covered, are of singular use in retaining the small dust that falls from the chives of the flowers, of which the wax is formed, as will be observed hereafter. The belly of the bee consists of six rings, which slide over one another, and may therefore be lengthened or contracted at pleasure; and the inside of this part of the body contains the intestines, the bag of honey, the bag of poison, and the sting. The office of the intestines is the same as in other animals. The bag of honey is transparent and crystal, containing the sweet juices extracted from flowers, which the bee discharges into the cells of the magazine for the support of the community in winter. The bag of poison hangs at the root of the sting, through the cavity of which, as through a pipe, the bee ejects some drops of this venomous liquor into the wound, and so renders the pain more excessive. The mechanism of the sting is admirable, being composed of two darts, inclosed within a sheath that tapers into a fine point, near which is an opening to let out the poison. The two darts are ejected through another aperture, which, being armed with several sharp beards like those of fish-hooks,

hooks, are not easily drawn back again by the bee ; and indeed she never disengages them if the wounded party happens to start and put her into confusion ; but if one can have patience to continue calm and unmoved, she clinches those lateral points round the shaft of the dart, by which means she recovers her weapon, and gives less pain to the person stung. The liquor which at the same she infuses into the wound, causes a fermentation, attended with a swelling, which continues several days ; but that may be prevented by immediately pulling out the sting, and enlarging the puncture, to let the venomous matter have room to escape.

Let us now consider the generation, polity, and labours of these insects, the true knowledge of which is very much owing to the modern invention of glass-hives, through which all the secrets of the community are laid open to a curious observer. Any person who carefully examines a hive at different seasons of the year, will distinguish three sorts of bees ; of which the far greater number are the common working bees, who do all the business of the hive, and seem to be neither male nor female. The working bees are represented on Plate III. fig. 5. The second sort, called drones, are the males, and somewhat larger than the former as fig. 6. They have no sting, nor even stir from the hive, but live upon the honey prepared by the others. The third sort is a much larger and longer bodied bee, of which there are often but one in every swarm or colony of young bees, who are from time to time detached from the hive in search of another habitation. This large bee is what the ancients called the king, from the respect they always saw paid to it by other bees ; but being the female, the moderns more properly give it the title of queen, or mother of the swarm. See Plate III. fig. 7.

When these industrious insects begin their works, it is observed they divide themselves into four parties, one of which is destined to the fields to provide materials for the structure : the second works upon those materials, and forms them into a rough sketch of the dimensions and partitions of the cells ; the third examines and adjusts the angles, removes the superfluous wax, polishes the work, and gives it its necessary perfection ; and the fourth is employed in bringing provisions to the labourers that build them, because polishing is not so laborious. They begin their work at the top of the hive, continuing downwards to the bottom, and from one side to the other ; and to make it the more solid they use a sort of tempered wax, resembling glue. The form of the cells of the honey-comb is hexagonal, which figure, and besides what is common with a square and equilateral triangle, has the advantage of including a greater space within the same surface.

The expedition of the bees in their labours is almost incredible ; for notwithstanding the elegance and just proportions of the work, they are so indefatigable, that they will, in one day, finish a honey-comb a foot long, and six inches broad, capable of receiving three thousand bees.

It is not easy to know, particularly, the manner in which they employ themselves at this work, on account of the number of bees then in motion, by which means the eye can hardly distinguish any thing but confusion. We have however been able to observe the following particulars : some bees, bearing in each of their talons a little piece of wax, are seen running to the places where their companions are at work upon the combs ; at their arrival they fasten the wax to the work by means of the same talons, which they apply sometimes to the right, and sometimes to the left. Each bee is employed but a short time on this work, when another takes its place.

While a part of the bees are at work in constructing the cells, others are employed in perfecting those that are newly modelled, finishing the angles, sides, and bases, in so exquisite a manner, and with such remarkable delicacy, that three or four of these sides laid upon one another, are not thicker than a leaf of common paper ; and because the entrance of the cell, which is adapted to the size of the bee, would on account of this delicacy, be subject to break, they strengthen the entrance of each cell with a border of wax.

We have already observed, that the bees which build the cells work but a little while at a time ; but it is different with regard to those that polish them, for they work for a long while, and with great expedition, never intermitting their labour, unless it be to carry out of the cell the particles of wax taken off in polishing : and, to

prevent this wax from being lost, other bees stand ready to receive it from the polishers, and carry it to some other part, in order to its being employed.

Each comb has two rows of cells opposite to each other, which have their common bases. The thickness of each comb is something less than an inch ; and, consequently, the depth of each cell about five lines : but at the same time the breadth of each is little more than two.

All the combs are constructed with cells of this size, except a small number of others in some particular parts of the hive, which are larger and appropriated to the lodging eggs, that afterwards become drones, or malebees.

There are also, in some parts of the hive, three or four cells bigger than the others, and constructed in a different manner. They are of a spheroidal figure, open in the inferior part, and attached to the extremities of the combs.

When the cells are completed, the queen takes possession of those she likes best to deposit her eggs in, and the rest are left to be filled with honey. She lays one egg in each cell, and sometimes more than an hundred of those eggs in a day ; but what is still more remarkable, she lays those eggs which are to produce common bees in cells of the common shape and size ; those that are to become drones or males, in the cells of a larger size, and deposits those which are to become females, like herself, in the spheroidal cells already described.

These eggs, after lying some time in the cells, are hatched into maggots, and fed with honey ten or twelve days, after which the other bees close up the cells with a thin piece of wax ; and under this covering they become gradually transformed into bees, in the manner as silk-worms are into butterflies. Having undergone this change, the young bees pierce through their waxen doors, wipe off the humidity from their little wings, take their flight into the fields, rob the flowers of their sweets, and are perfectly acquainted with every necessary circumstance of their future conduct. As to the males or drones, which are destined only to propagate their species, they live very comfortably for about three months after they are hatched ; but when that time is over, and the females are impregnated, the common bees either kill them, or drive them from the hive, as burthenome to the community, and not a drone is to be found till the next season.

The method in which the bees collect their wax and honey deserves to be a little explained. At the bottom of all flowers there are certain glands which contains more or less honey, that is, the most exalted particles of the sugary juices of the plant. These juices the bee sucks up with her proboscis or trunk above-mentioned, and draws it into her mouth ; and when it has thus taken a sufficient quantity into her stomach, returns to the hive, and discharges the honey into the common magazine.

When the cells prepared to receive it are full, the bees close up some with wax till they have occasion for the honey ; the rest they leave open, to which all the members of the society resort, and take their repast with a very instructive moderation.

It is an excellent observation of a modern author, that the hive is a school to which numbers of people ought to be sent ; prudence, industry, benevolence, public spiritedness, oeconomy, neatness, and temperance, are all visible among the bees. These little animals are actuated by a social spirit, which forms them into a body politic, intimately united, and perfectly happy. They all labour for the general advantage ; they are all submissive to the laws and regulations of the community : having no particular interest, no distinction but those which nature or the necessities of their young have introduced amongst them. We never see them dissatisfied with their condition, or inclinable to abandon the hive in disgust, or find themselves slaves or necessitous : on the contrary, they think themselves in perfect freedom, and perfect affluence ; and such indeed is their real condition. They are free, because they only depend on the laws ; they are happy, because the concurrence of their several labours inevitably produces abundance, which contributes to the riches of each individual. Let us compare human societies with this, and they will appear altogether monstrous. Necessity, reason, and philosophy, have established them for the commendable purposes of mutual aid and benefits : but a spirit of selfishness

destroys all ; and one half of mankind, to load themselves with superfluities, leave the other destitute of common necessities.

Wax is composed of the farina, or dust, formed on the apices of flowers. This the bees collect, and with their fore-feet and jaws, roll up into little balls, which they convey, one at a time, to the feet of their middle legs, and from thence to the middle joints of their hind-legs, where there is a small cavity like a spoon to receive it. These balls are not, however, true wax, but the substance or basis of it: to reduce this crude substance into wax, it must first be digested in the body of the bee.

After the bees have brought home this crude substance, they eat it by degrees ; or, at other times, three or four bees come and ease the loaded bee by eating each of them a share, the loaded bee giving them a hint so to do. Hunger is not the motive of their thus eating the balls of waxy matter, especially when a swarm is first hived ; but it is their desire to provide a speedy supply of real wax for making their combs. At other times, when there is no immediate want of wax, the bees lay this matter up in repositories, to keep it in store.

When this waxy matter is swallowed, it is by the digestive powers of the bee, converted into real wax, which the bees again disgorge as they work it up into combs ; for it is only while thus soft and pliant from the stomach that they can fabricate it properly. That the wax thus employed is taken from their stomachs, appears from their making a considerable quantity of comb soon after they are hived, and even on any tree or shrub where they have rested but a short while before their being hived, though no balls were visible on their legs, excepting those of a few which may be just returned from the field.

Bees collect crude wax also for food ; for if this was not the case, there would be no want of wax after the combs are made : but they are observed, even in old hives, to return in great numbers loaded with such matter, which is deposited in particular cells, and is known by the name of *bee-bread*. We may guess that they consume a great deal of this substance in food, by the quantity collected, which, by computation, may in some hives amount to an hundred weight in a season, whilst the real wax in such an hive does not perhaps exceed two pounds.

But besides the three substances, honey, wax, and bee-bread, already mentioned, there is another with which the bees close every crevice in their hives, and which is called propolis. It is a kind of resin easy to be rolled out, much more tenacious than wax, and more easily fixed. It does not seem to require any preparation, being a real resin, which they collect from trees, and employ as they find it. It grows very hard in the hive, but may be softened by heat. It is dissoluble in spirit of wine. It commonly diffuses a very agreeable smell when heated. Its outward colour is of a reddish brown ; its inside resembles wax, and is a little yellowish. When the bees make use of it, it is soft and pliable ; but it hardens daily, and becomes in time harder than wax. This propolis serves also for another purpose, which is, that when a snail, slug, or any other creature too large to be carried out by the bees, has been slain in the hive, they cast it over with this substance, and thereby prevent the bad effects of the putrid smell arising from dead bodies.

When the hive is become too much crowded, by the addition of the young brood, a part of the bees think of finding themselves a more commodious habitation, and with that view single out the most forward of the young queens. A new swarm is therefore constantly composed of one queen at least, and of several thousand working bees, as well as of some hundreds of drones. The working bees are some old, some young.

Scarce has the colony arrived at its new habitation, when the working bees labour with the utmost diligence, to procure materials for food and building. Their principal aim is not only to have cells in which they may deposit their honey ; a stronger motive seems to animate them. They seem to know that their queen is in haste to lay her eggs. Their industry is such, that in twenty-four hours they will have made combs twenty inches long, and wide in proportion. They make more wax during their first fortnight, if the season is favourable, than they do during all the rest of the year. Other bees are at the same time busy in stopping all the holes and crevices they find in their new hive, in order to guard against the entrance of insects which covet their honey

their wax, or themselves ; and also to exclude the cold air, for it is indispensably necessary that they be lodged warm.

When the bees first settle in swarming, indeed when they at any time rest themselves, there is something very particular in their method of taking their repose. It is done, by collecting themselves in a heap, and hanging to each other by their feet. They sometimes extend these heaps to a considerable length. It would seem probable to us, that the bees from which the others hang, must have a considerable weight suspended to them. All that can be said is, that the bees must find this to be the situation agreeable to themselves. They may perhaps have a method of distending themselves with air, thereby to lessen their specific gravity, in the same manner as fishes do, in order to alter their gravity, compared with water.

When a swarm divides into two or more bands which settle separately, this division is a sure sign that there are two or more queens among them. One of these clusters is generally larger than the other. The bees of the smaller cluster, or clusters, detach themselves by little and little, till at last the whole, together with the queen, or queens, unite with the larger cluster. As soon as the bees are hived and settled, the supernumerary queen, or queens, must be sacrificed to the peace and tranquillity of the hive. This execution generally raises a considerable commotion in the hive, and several other bees, as well as the queen, or queens, lose their lives. Their bodies may be observed on the ground, near the hive. The queen that is chosen is of a more reddish colour than those which are destroyed ; so that fruitfulness seems to be a great motive of preference in bees ; for the nearer they are to the time of laying their eggs, the bigger, larger, and more shining are their bodies.

For three or four nights before a swarm falls forth, there is in the hive a peculiar humming noise, of which authors give very different descriptions, probably owing to the strength of imagination in each. Every sound among bees arises from their striking their wings against the air : their wings being their sole organ of sound, if we may be allowed the expression. By moving their wings more or less forcibly and swiftly, they beat the air, and form the varied confused sounds which we call humming. The noise which foretells their swarming is easily distinguished by those who are accustomed to it, and is more especially observed before the casts, or second and following swarms. The hive appears so full of bees, that part of them hang in clusters on the outside ; and the drones are perceived flying about in greater numbers than usual. But the most certain sign, and which indicates this event to be on that day, is, that the bees refrain from flying into the fields, though the season seems inviting. Just before they take their flight, there is an uncommon silence in the hive, and this continues for some time : but as soon as one breaks forth, they all follow, and are instantly on the wing. They seldom swarm before the sun has warmed the air ; that is, not before ten in the morning, and seldom later than three in the afternoon ; and the time of the year in which they most generally swarm, is from the middle of May to the end of June : but sometimes sooner or later, according as the season is more or less favourable. The earliest swarms do not always prove the best, especially if they are so early as the end of April or beginning of May : for the weather often is afterwards so wet and cold, that they are frequently in danger of being destroyed, or greatly reduced by famine. Though swarms which issue forth so late as July are not in danger of a present famine ; yet, they scarcely have time and opportunity to lay in a sufficient store for the winter. Towards the season of swarming, the door of the hive should be enlarged, to give the bees the greater freedom to issue out ; and it should likewise remain so for young swarms, during the first fortnight or three weeks, to allow the freer entrance to the bees, at that time extremely busy in collecting their necessary stores. The entrance should afterwards be gradually lessened, to prevent the otherwise easy access of enemies, of which there is great danger, especially as the autumn advances.

Hives continue sometimes to send forth swarms till the old hive becomes too much weakened, part that of it is empty. It is probable, that the prolific young queens prompt the bees to swarm thus frequently : for it is certain that if there is not a young mother qualified to bring forth a numerous progeny, though there be ever so great a number of bees, they will all remain, and die rather than quit the hive.

When-

Whenever the bees of a swarm fly too high, they are made to descend lower, and disposed to settle, by throwing among them handfuls of sand or dust: probably the bees mistake this for rain. It is usual at the same time to beat on a kettle or frying-pan; perhaps from its being observed that the noise of thunder prompts such bees as are in the field to return home. Precautions of this kind are the more necessary, if, as Dr. Warder, in his *Truë Amazont*, observes, "the bees always provide a place for their habitation before they swarm; either in some hollow tree, or in the hollow part of some old building, or in some deserted hive, which the swarms have already prepared, by cleaning out whatever may be offensive to their cleanly nature." Of this he gives an instance; and concludes, that "though they provide themselves with a house before they swarm, and take much pains about it; yet if you are early enough in your taking the swarm, and they find themselves at unawares in a convenient house, they have no mind generally to leave it: but if they rise again the same or next day, be sure not to hive them in the same hive again, for it is plain they have some dislike to it."

That the bees provide themselves a habitation before they swarm, is a very just observation, a remarkable instance of which I was witness of at a gentleman's seat in Gloucestershire some years ago, where, walking in the garden in which were several bee-hives in the month of June, the bees were in full work, and passing in and out of the hives in great numbers, as is usual in fine weather at that season. In one hive only a very few bees were passing, and I was told it was an empty hive. I turned it up, and found it so, except a few bees near the crown of it, and the reason of their being there did not then occur to me: but next day a woman who lived in the neighbourhood, came running to the gardener, acquainting him, that she had just lost a swarm of bees she had hived the evening before, which she saw go off, and had followed them to the garden wall, and requested she might be permitted to take them away, being persuaded that they were lodged somewhere in the garden. Upon search, a swarm was found in the hive that I had observed was empty the day before: some of the bees were in the hive, and the rest at the mouth of it, on the outside. In the evening the woman brought her hive, hived the bees in it a second time and carried them home at night: but next morning they came off again, and settled as at first upon the empty hive in the gentleman's garden. As it appeared by this that the woman's hive was disagreeable to them, she was allowed to carry the bees home in the hive they had chosen for themselves, which she placed where she had put them at first, and in this hive they remained quiet, and soon went to work.

I have related this, not only in confirmation of what is observed above, of bees providing a habitation for themselves before they swarm, but also for another reason: for having once a pretty large apiary, consisting of common straw hives, and boxes of various constructions, some of which happening to be empty, I found a swarm had taken possession of one of them. After this I placed some empty hives every summer in my apiary, whereof one or more were commonly filled by swarms from my other hives, which saved the trouble of watching and hiving them. And sometimes swarms would settle in them, that I knew not whence they came. In this way a person desirous of having bees might obtain some, without any trouble, if the situation is good: by placing a few empty hives in readiness for them, and many good swarms might be thus saved, that fix themselves in hollow-trees, old walls, and other inaccessible places, where they are of no use to any body. All the preparation necessary for these empty hives is, that they be very sweet and perfectly clean, and the insides well rubbed with a clean coarse linen cloth, to break off the short straws, or other roughness in the hive. Some in dressing their hives, rub the insides of them with sweet herbs, and some with honey: but I made no other preparations, than rubbing off the short straws, and keeping them very clean. Bees are commonly put into straw hives; and swarms seem to take to these more readily than to boxes, when left to their own choice.

As soon as the swarm is settled, the bees which compose it should be got into a hive with all convenient speed, to prevent their taking wing again. If they settle on a small branch of a tree, easy to be come at, it may be cut off, and laid upon a cloth; the hive being

ready immediately to put over them. If the branch cannot be conveniently cut, the bees may be swept from off it into a hive. Lodge but the queen in the hive, and the rest will soon follow. If the bees must be considerably disturbed in order to get them into the hive, the most advisable way is to let them remain in the place where they have pitched, till the evening, when there is less danger of their taking wing. If it be observed that they still hover about the place they first alighted upon, the branches there may be rubbed with rue, or elder leaves, or any other thing distasteful to them, to prevent their returning to it.

The hive employed on this occasion should be cleaned with the utmost care, and its inside be rubbed very hard with a coarse cloth, to get off the loose straws, or other impurities, which might cost them a great deal of time and labour to gnaw away. It may then be rubbed with fragrant herbs or flowers, the smell of which is agreeable to the bees, or with honey.

The hive should not be immediately set on the stool where it is to remain, but should be kept near the place at which the bees settle, till the evening, lest some stragglers should be left. It should be shaded, either with boughs, or with a cloth, that the too great heat of the sun may not annoy the bees.

We sometimes see a swarm of bees, after having left their hive, and even alighted upon a tree, return to their first abode. This never happens but when the young queen did not come forth with them for want of strength, or perhaps courage to trust to her wings for the first time; or possibly from a consciousness of her not being impregnated.

Bees are not apt to sting when they swarm: therefore it is not necessary then to take much extraordinary precaution against them. It is however advisable for those who are not accustomed to them, to cover their face and hands.

A second swarm scarcely is, and much less are the subsequent ones, worth keeping single; because, being few in number, they cannot allow so large a proportion of working bees to go abroad in search of store, as more numerous swarms can, after having appointed a proper number for the various works to be done within. For this reason it is advisable to unite two or more of these last or latter swarms into one hive, so as to procure a sufficient number of bees in one hive. Bees sometimes swarm so often, that the mother-hive is too much weakened. In this case, the swarms should be restored back; and this should also be done when a swarm produces the first summer, as it sometimes does. The best way, indeed, is to prevent such swarming, by giving the bees more room: though this, again, will not answer when there is a young pregnant queen; she well knowing that her life is the forfeit of her remaining at home.

The usual method of uniting swarms is very easy. Spread a cloth at night upon the ground close to the hive, in which the two casts of swarms are to be united; lay a stick across this cloth; then fetch the hive with the new swarm, set it over the stick, give a smart stroke on the top of the hive, and all the bees will drop down upon the cloth in a cluster. This done, throw aside the empty hive, take the other from off the stool, and set this last over the bees, who will soon ascend into it, mix with those already there, and become one and the same family. Others, instead of striking the bees down upon the cloth, place with its bottom upmost the hive in which the united swarms are to live, and strike the bees of the other hive down into it. The former of these hives is then restored to its natural situation, and the bees of both hives soon unite. If some bees still adhere to the other hive, they may be brushed off on the cloth, and they will soon join their brethren. Or one may take the following method, which gives less disturbance to the bees. Set with its mouth upmost the hive into which the young swarm has been put, and set upon it the other hive. The bees in the lower hive, finding themselves in an inverted situation, will soon ascend into the upper.

Though all writers acknowledge, that one of the queens is constantly slain on these occasions, and generally a considerable number of the working bees; yet none of them, Columella excepted, has proposed the easy remedy of killing the queen of the latter cast or swarm before the union is made; a means by which the lives of the working bees may be preserved. This may be done, either by intoxicating them, and then picking her out, or by searching her out when the bees are beating down upon the cloth; for this being done in the night, to

prevent the battle which might otherwise ensue, there will be no great difficulty in finding her.

A large swarm may weigh eight pounds, and so gradually less, to one pound: consequently a very good one may weigh five or six pounds. All such as weigh less than four pounds should be strengthened, by uniting to each of them a less numerous swarm. The size of the hive should be proportioned to the number of the bees; and, as a general rule, it should be rather under than over sized, because bees require to be kept warmer than a large hive will admit of.

Columella directs, that the apiary, or bee-garden, should face the south, in a place neither too hot, nor too much exposed to the cold; that it be in a valley, in order that the loaded bees may with the greater ease descend to their homes; that it be near the mansion-house, on account of the convenience of watching them, but so situated as not to be exposed to noisome smells, or to the din of men or cattle; that it may be surrounded with a wall, which however should not rise above three feet high; that, if possible, a running stream be near them, or, if that cannot be, that water be brought near them, in troughs, with pebbles or small stones in the water, for the bees to rest on whilst they drink; or that the water be confined within gently declining banks, in order that the bees may have safe access to it; they not being able to produce either combs, honey, or food for their maggots, without water. That the neighbourhood of rivers or basins of water with high banks be avoided because winds may whirl the bees into them, and they cannot easily get on shore from thence to dry themselves; and that the garden, in which the apiary stands, be well furnished with such plants as affords the bees plenty of good pasture. The trees of this garden should be of the dwarf kind, and their heads bushy, in order that the swarms which settle on them may be the more easily hived.

The proprietor should be particularly attentive that the bees have also in their neighbourhood such plants as yield them plenty of food. Columella enumerates many of these fitted to a warm climate: among them he mentions thyme, the oak, the pine, the sweet smelling cedar, and all fruit trees. Experience has taught us, that furz, broom, mustard, clover, heath, buck-wheat, &c. are excellent for this purpose. Pliny recommends broom, in particular, as a plant exceedingly grateful, and very profitable to bees; and Mr. Bradley speaks highly of the advantages which arise from the planting of it for the food of these useful insects. See the article BROOM.

Plantations of mustard, of the flowers of which bees are extremely fond, may be kept in bloom for several weeks running.

Great improvements may also certainly be made in the essential article of providing plenty of pasture for bees, whenever this subject shall be more carefully attended to than it, unfortunately, has hitherto been. A rich corn country is well known to be a barren desert to them during the most considerable part of the year; and therefore the practice of other nations, in shifting the places of abode of their bees, well deserves our imitation.

Columella informs us, that, as few places are so happily situated as to afford the bees proper pasture both in the beginning of the season and also in the autumn, it was the advice of Celsus, that after the vernal pastures are consumed, the bees should be transported to places abounding with autumnal flowers; as was practised by conveying the bees from Achaia to Artica, from Eubœa and the Cyclad islands to Scyrus, and also in Sicily, where they were brought to Hybla from other parts of the island. He likewise directs, that the hives be carefully examined before they are removed from one place to another, and to take out such combs as appear old, loose, or have moths in them, reserving only those that are sound, in order that the hive may be stored with combs collected from the best flowers.

Mr. Maillet, in his curious description of Egypt, relates, that "spite of the ignorance and rusticity which have got possession of that country, there yet remain in it several footsteps of the industry and skill of the ancient Egyptians. One of their most admirable contrivances is, their sending their bees annually into distant countries, in order to procure them sustenance there, at a time when they could not find any at home; and their afterwards bringing them back, like shepherds who should travel with their flocks, and make them feed as they go. It was observed by the ancient inhabitants of Lower Egypt, that all plants blossomed, and the fruits of the earth ripened, above six weeks earlier

in Upper Egypt than with them. They applied this remark to their bees; and the means then made use of by them, to enable these useful industrious insects to reap advantage from the more forward state of nature there, were exactly the same as are now practised, for the like purpose, in that country. About the end of October, all such inhabitants of the Lower Egypt as have hives of bees, embark them on the Nile, and convey them upon that river quite into Upper Egypt; observing to time it so that they arrive there just when the inundation is withdrawn, the lands have been sown, and the flowers begin to bud. The hives thus sent are marked and numbered by their respective owners, and placed pyramidically in boats prepared for the purpose. After they have remained some days at their farthest station, and are supposed to have gathered all the wax and honey they could find in the fields within two or three leagues around, their conductors convey them, in the same boats, two or three leagues lower down, and there leave the laborious insects so long time as is necessary for them to collect all the riches of this spot. Thus, the nearer they come to the place of their more permanent abode, they find the productions of the earth, and the plants which afford them food, forward in proportion. In fine, about the beginning of February, after having travelled through the whole length of Egypt, gathering all the rich produce of the delightful banks of the Nile, they arrive at the mouth of that river, towards the ocean; from whence they set out, and from whence they are now returned to their several homes: for care is taken to keep an exact register of every district from whence the hives were sent in the beginning of the season, of their numbers, of the names of the persons who sent them, and likewise of the mark or number of the boat in which they were placed."

The author of the Natural History of Bees, gives the following account of what is practised in this way in France; an example well worthy of our imitation in many parts of this kingdom. "M. Proutaut, says he, keeps a great number of hives. His situation is one of those in which flowers become rare or scarce very soon, and where few or none are seen after the corn is ripened. He then sends his bees into Beauce, or the Gatinois, in case it has rained in those parts. This is a journey of about twenty miles, which he makes them take: but if he concludes that the bees could not meet in either of those countries, wherewith to employ themselves advantageously, he then has them carried into Sologne about the beginning of August, as knowing that they will there meet with a great many fields of buck-wheat in flower, which will continue so till about the end of September. His method of transporting them is thus. His first care is, to examine those hives, some of whose honey-combs might be broken or separated by the jolting of the vehicle: they are made fast one to the other, and against the sides of the hive, by means of small sticks, which may be disposed differently as occasion will point out. This being done, every hive is set upon a packing-cloth, or something like it, the threads of which are very wide: the sides of this cloth are then turned up, and laid on the outside of each hive, in which state they are tied together with a piece of small pack-thread wound several times round the hive. As many hives as a cart built for that purpose will hold, are afterwards placed in this vehicle. The hives are set two and two, the whole length of the cart. Over these are placed others; which make, as it were, a second story or bed of hives. Those which are stored with combs should always be turned topsy-turvy. It is for the sake of their combs, and to fix them the better, that they are disposed in this manner; for such as have but a small quantity of combs in them, are placed in their natural situation. Care is taken in this stowage, not to let one hive stop up another, it being essentially necessary for the bees to have air; and it is for this reason they are wrapped up in a coarse cloth, the threads of which were wove very wide, in order that the air may have a free passage, and lessen the heat which these insects raise in their hives; especially when they move about very tumultuously, as often happens in these carts. Those used for this purpose in Yèvre, hold from thirty to forty-eight hives. As soon as all are thus stowed, the caravans set out. If the season is sultry they travel only in the night; but a proper advantage is made of cool days. You will imagine that they do not ride post. The horses must not be permitted even to trot; they are led slowly, and through the smoothest roads. When there are not combs in the hives sufficient to support the bees during their

their journey, the owner takes the earliest opportunity of resting them wherever they can collect wax. The hives are taken out of the cart, then set upon the ground, and after removing the cloth from over them, the bees go forth in search of food. The first field they come to serves them as an inn. In the evening, as soon as they are all returned, the hives are shut up; and being placed again in the cart, they proceed in their journey. When the caravan is arrived at the journey's end, the hives are distributed in the gardens, or in fields adjacent to the houses of different peasants, who, for a very small reward, undertake to look after them. Thus it is that, in such spots as do not abound with flowers at all seasons, means are found to supply the bees with food during the whole year."

These instances of the great advantages which attend shifting of bees in search of pasture, afford an excellent lesson to many places in this kingdom: they direct particularly the inhabitants of the rich vales, where the harvest for bees ends early, to remove their stocks to places which abound in heath, this plant continuing in bloom during a considerable part of the autumn, and yielding great plenty of food to bees. Those in the neighbourhood of hills and mountains will save the bees a great deal of labour, by taking also the advantage of shifting their places of abode.

We come now to explain the most inhuman method commonly practised of taking bees, which consists in wantonly destroying the whole swarm, in order to enjoy the fruits of their labours.

Were we to kill the hen for her egg, the cow for her milk, or the sheep for the fleece it bears, every one would instantly see how much we should act contrary to our own interest; and yet this is practised every year in regard to bees. Would it not argue more wisdom in us to be contented with taking away only a portion of their wax and honey, as is the practice of many countries? The common method here is, that when those which are doomed for slaughter have been marked out (which is generally done in September) a hole is dug near the hive, and a stick, at the end of which is a rag that has been dipped in melted brimstone, being stuck in that hole, the rag is set on fire, the hive is immediately set over it, and the earth is instantly thrown up all around, so that none of the smoke can escape. In a quarter of an hour, all the bees are seemingly dead; and they will soon after be irrecoverably so, by being buried in the earth that is returned back into the hole: I say, they will soon be absolutely killed by this last means; because it has been found, by experiment, that all the bees which have been affected only by the fume of the brimstone, recover again, excepting such as have been singed or hurt by the flame. Hence it is evident, that the fume of brimstone might be used for intoxicating the bees, with some few precautions. The heaviest and the lightest hives are alike treated in this manner; the former, because they yield the most profit, with an immediate return; and the latter, because they would not be able to survive the winter. Those hives which weigh from fifteen to twenty pounds, are thought to be the fittest for keeping.

The practice of the ancients was, however, very different from this: they were content to share with these industrious insects the produce of their labours; and some very laudable attempts have been made in our own country, to attain the desirable end of getting the honey and wax without destroying the bees. John Geddy, esq; published, in the year 1665, his invention of boxes for preserving the lives of bees. These were improved by Joseph Warder, physician, at Croydon, who at the same time embellished his account of the structure and use of these boxes, with several other curious circumstances concerning bees, in his work intitled, *The True Amazons, or the Monarchy of Bees*. Two very worthy clergymen, the reverend Mr. John Thorley of Oxford, and the reverend Mr. Stephen White, M. A. rector of Holton in Suffolk, have brought the method of preserving the lives of bees to still greater perfection. We shall relate the opinions and practice of each, beginning with Mr. Thorley, who lived many years before Mr. White, and add to their accounts the best improvements that have been lately made in foreign countries.

Mr. Thorley, in his *Enquiry into the Nature, Order, and Government of Bees*, thinks colonies preferable to hives, for the following reasons. First, the more certain preservation of very many thousands of these noble and useful creatures: Secondly, their greater strength (which consists in numbers), and consequently their greater safety

from robbers: Thirdly, their greater wealth, arising from the united labours of the greater number. He tells us, that he has in some summers taken two boxes filled with honey from one colony, and yet sufficient store has been left for their maintenance during the winter, each box weighing forty pounds. Add to these advantages, the pleasure of viewing them with the greatest safety, at all seasons, even in the busiest time of gathering, and their requiring a much less attendance in swarming time. The bees thus managed are also more effectually secured from wet and cold, from mice, and other vermin.

His boxes are made of deal, which, being spongy, sucks up the breath of the bees sooner than a more solid wood would do. Yellow dram-deal, thoroughly seasoned, is the best.

An octagon, being nearer to a sphere, is better than a square form: for as the bees, in winter, lie in a round body near the center of the hive, a due heat is then conveyed to all the out parts, and the honey is kept from candying.

The dimensions which Mr. Thorley, after many years experience, recommends for the boxes, are ten inches deep, and twelve or fourteen inches broad, in the inside. He has tried boxes containing a bushel or more, but found them not to answer the design like those of a lesser size.

The top of the box should be made of an entire board, a full inch thick after it has been planed, and it should project on all sides at least an inch beyond the dimensions of the box. In the middle of this top there must be a hole five inches square, for a communication between the boxes; and this hole should be covered with a sliding shutter, of deal or elm, running easily in a groove over the back window. The eight pannels, nine inches deep, and three quarters of an inch thick when planed, are to be let into the top so far as to keep them in their proper places; to be secured at the corners with plates of brass, and to be cramped with wires at the bottom, to keep them firm; for the heat in summer will try their strength. There should be a glass window behind, fixed in a frame, with a thin deal cover, two small brass hinges, and a button to fasten it. This window will be sufficient for inspecting the progress of the bees. Two brass handles, one on each side, are necessary, to lift up the box: these should be fixed in with two thin plates of iron, near three inches long, so as to turn up and down, and put three inches below the top-board, which is nailed close down with sprigs to the other parts of the box.

Those who chuse a frame within, to which the bees may fasten their combs, need only use a couple of deal sticks of an inch square, placed across the box, and supported by two pins of brass; one an inch and a half below the top, and the other two inches below it; by which means the combs will quickly find a rest. One thing more, which perfects the work, is a passage four or five inches long, and less than half an inch deep, for the bees to go in and out at the bottom of the box.

Mr. Thorley, son to the above-mentioned clergyman, has improved his father's method of managing bees; and having been convinced, from near sixty years experience, that his bee-hives would be productive of much greater profit to the owners of bees, and also render that cruel and ungenerous practice of destroying these animals not only unnecessary, but pernicious, presented a bee-hive of this construction to the Society of Arts, &c. in the Strand, who readily purchased another of his hives filled with honey, &c. that they might be inspected by the curious, and brought into universal use; and from this bee-hive the view on Plate III. fig. 8. was drawn. The society, persuaded that the invention would prove of the greatest advantage to this country, published a premium of two hundred pounds, in order to introduce Mr. Thorley's, or some other method of a similar kind, whereby much larger quantities of honey and wax might be procured, and, at the same time, the lives of these laborious and useful insects preserved.

The bottom part, marked *a*, is an octangular bee-box, made of deal boards, about an inch in thickness, the cover of which is about 17 inches in diameter, but the internal part only 15½, and its height 10 inches. In the middle of the cover of this octangular box is a hole, which may be opened or shut at pleasure, by means of a slider *d*. In one of the pannels is a pane of glass, covered with a wooden door, *c*. The entrance, *f*, at the bottom of the box, is about three inches and a half broad, and half an inch high. Two slips of deal, about half an inch square, cross each other in

the center of the box, and are fastened to the pannels by means of small screws. To these slips the bees fasten their combs.

In this octangular box the bees are hived, after swarming in the usual manner, and there suffered to continue till they have built their combs, and filled them with honey, which may be known from opening the door, and viewing their works through the glass-pane, or by the weight of the hive. When the bee-master finds his laborious insects have filled their habitation, he is to place a common beehive of straw, represented at *b*, made either flat at the top, or in the common form, on the octangular box, and draw out the slider, by which a communication will be opened between the box and the bee-hive; the consequence of which will be, that those laborious insects will fill this hive also with the product of their labours. When the bee-master finds the straw-hive is well filled, he may push in the slider, and take it away, placing another immediately in its room, and then drawing out the slider. These indefatigable creatures will then fill the new hive in the same manner. By proceeding in this method, Mr. Thorley assured the Society that he had taken three successive hives, filled with honey and wax, from one single hive, during the same summer; and that after he had laid his insects under so large a contribution, the food still remaining in the octangular box was abundantly sufficient for their support during the winter. He added, that if this method was pursued in every part of the kingdom, instead of that cruel method of putting the creatures to death, he was persuaded, from long experience, that wax would be collected in such plenty that candles might be made with it, and sold as cheap as those of tallow are at present.

Mr. Thorley has also added another part to his beehive, which cannot fail of affording the highest entertainment to a curious and inquisitive mind. It consists of a glass receiver, represented at *D*, eighteen inches in height, eight inches in diameter at the bottom, and in the greatest part thirteen. This receiver has a hole at the top, about an inch in diameter, through which a square piece of deal *E* is extended nearly to the bottom of the vessel, having two cross bars to which the bees fasten their combs. When the bees have filled their straw-hives, (which must have a hole in the center, covered with a piece of tin) Mr. Thorley places the glass *c* upon the top of the straw-hive, and draws out the piece of tin: the bees, now finding their habitation enlarged, pursue their labours with such alacrity, that they fill this glass-hive likewise with their stores. And as this receptacle is wholly transparent, the curious observer may entertain himself with viewing the whole progress of their works. One of the hives, now deposited at the Society's room in the Strand, is filled with the produce of the labours of those insects; and the glass-hive is supposed to contain about thirty-eight pounds of honey.

It will, however, be necessary to cover the glass with an empty hive of straw, or at least with a cloth, which may be easily removed when you inspect your bees, lest too much light prevent your insects from working.

When the glass is completely filled, slide a tin-plate between it and the hive or box, so as to cover the passage, and in half an hour the glass may be taken off with safety. What few bees remain in it, will readily go to their companions. He then very obligingly offers his service and farther information to any gentleman or lady whose curiosity may incline them to inspect his apiary. He has added a glass window to his straw-hives, in order to see what progress the bees make; which is of some importance, especially if one hive is to be taken away while the season still continues favourable for their collecting of honey: for when the combs are filled with honey, the cells are sealed up, and the bees forsake them, and reside mostly in the hive in which their works are chiefly carried on. Observing also, that the bees were apt to extend their combs through the passage of communication into the upper hive, whether glass or other, which rendered it necessary to divide the comb when the upper hive was taken away, he now puts in that passage a wire-screen, or netting, the meshes of which are large enough for a loaded bee to go easily through them; this prevents the joining of the combs from one box to the other, and consequently obviates the necessity of cutting them, and of spilling some honey, which, running down amongst a crowd of bees, used before to incommode them much; it being difficult for them to clear their wings of it.

The reverend Mr. Stephen White, rector of Holton in Suffolk, informs us, that his fondness for these little

animals soon put him upon endeavouring, if possible, to save them from fire and brimstone; that he thought he had reason to be content to share their labours for the present, and great reason to rejoice if he could at any time preserve their lives, to work for him another year; and that the main drift of his observations and experiments has therefore been, to discover an easy and cheap method, suited to the abilities of the common people, of taking away so much honey as can be spared, without destroying or starving the bees, and by the same means to encourage seasonable swarms.

In his directions how to make the bee-boxes of his inventing, he tells us, speaking of the manner of constructing a single one, that it may be made of deal or any other well-seasoned boards which are not apt to warp or split. The boards should be near an inch thick: the figure of the box square, and its height and breadth nine inches and five eighths every way, measuring within. With these dimensions it will contain near a peck and an half. The front part must have a door cut in the middle of the bottom edge, three inches wide, and near half an inch in height, which will give free liberty to the bees to pass through, yet not be large enough for their enemy the mouse to enter. In the back part you must cut a hole with a rabbit in it, in which you are to fix a pane of the clearest and best crown-glass, about five inches in length, and three in breadth, and fasten it with putty: let the top of the glass be placed as high as the roof within-side, that you may see the upper part of the combs, where the bees with their riches are mostly placed. You will, by this means, be better able to judge of their state and strength, than if your glass was fixed in the middle. The glass must be covered with a thin piece of board, by way of shutter, which may be made to hang by a string, or turn upon a nail, or slide sideways between two mouldings. Such as are desirous of seeing more of the bees works, may make the glass as large as the box will admit, without weakening it too much; or they may add a pane of glass on the top, which must likewise be covered with a shutter, fastened down with pegs to prevent accidents.

The side of the box, which is to be joined to another box of the same form and dimensions, as it will not be exposed to the external air, may be made of a piece of slit deal not half an inch thick. This he calls the side of communication, because it is not to be wholly inclosed: a space is to be left at the bottom, the whole breadth of the box, and a little more than an inch in height, and a hole or passage is to be made at top, three inches long, and more than half an inch wide. Through these the bees are to have a communication from one box to the other. The lower communication being on the floor, our labourers, with their burthens, may readily and easily ascend into either of the boxes. The upper communication is only intended as a passage between the boxes, resembling the little holes, or narrow passes, which may be observed in the combs formed by our sagacious architects, to save time and shorten the way when they have occasion to pass from one comb to another; just as, in populous cities, there are narrow lanes and alleys, passing transversely from one large street to another.

In the next place you are to provide a loose board, half an inch thick, and large enough to cover the side where you have made the communication. You are likewise to have in readiness several little iron staples, an inch and half long, with the two points or ends bended down more than half an inch. The use of these will be seen presently.

You have now only to fix two sticks crossing the box from side to side, and crossing each other, to be a stay to the combs; one about three inches from the bottom, the other the same distance from the top; and when you have painted the whole, to make it more durable, your box is finished.

The judicious bee-master will here observe, that the form of the box now described is as plain as is possible for it to be. It is little more than five square pieces of board nailed together; so that a poor cottager, who has but ingenuity enough to saw a board into the given dimensions, and to drive a nail, may make his own boxes well enough, without the help or expence of a carpenter.

No directions are necessary for making the other box, which must be of the same form and dimensions. The two boxes differ from each other only in this, that the side of communication of the one must be on your right-hand, of the other on the left. Plate III. fig. 9. represents two of these boxes, with their openings of communication, ready to join to each other.

Mr.

Mr. White's manner of hiving a swarm into one or more of these boxes, is thus :

You are to take the loose board, and fasten it to one of the boxes, so as to stop the communications. This may be done by three of the staples before-mentioned ; one on the top of the box near the front, the two others on the back, near the top and near the bottom. Let one end of the staple be thrust into a gimblet-hole made in the box, so that the other end may go as tight as can be over the loose board, to keep it from slipping when it is handled. The next morning, after the bees have been hived in this box, the other box should be added, and the loose board should be taken away. This will prevent a great deal of labour to the bees, and some to the proprietor.

Be careful to fasten the shutter so close to the glass, that no light may enter through it : for the bees seem to look upon such light as a hole or breach in their house, and on that account may not so well like their new habitation. But the principal thing to be observed at this time, is to cover the box, as soon as the bees are hived, with a linen-cloth thrown loosely over it, or with green boughs, to protect it from the piercing heat of the sun. Boxes will admit the heat much sooner than straw-hives ; and if the bees find their house too hot for them, they will be wise enough to leave it. If the swarm be larger than usual, instead of fastening the loose board to one box, you may join two boxes together with three staples, leaving the communication open from one to the other, and then hive your bees into both. In all other respects, they are to be hived in boxes after the same manner as in common hives ; which being well known, it were needless here to give particular directions concerning it.

The door of the second box should be carefully stopped up, and be kept constantly closed, in order that the bees may not have any entrance but through the first box.

When the boxes are set in the places where they are to remain, they must be screened from the summer's sun, because the wood will be otherwise heated to a greater degree than either the bees or their works can bear ; and they should likewise be screened from the winter's sun, because the warmth of this will draw the bees from that lethargic state which is natural to them, as well as to many other insects, in the winter season. For this purpose, and also to shelter the boxes from rain, our ingenious clergymen has contrived the following frame :

Plate III. fig. 10. represents the front of a frame for twelve colonies ; *a, a*, are two cells of oak, lying flat on the ground, more than four feet long. In these cells you are to fix four oaken posts, about the thickness of such as are used for drying linen.

The two posts *b, b*, in the front, are about six feet two inches above the cells ; the other two standing backward, five feet eight inches.

You are next to nail some boards of slit deal horizontally from one of the fore-posts to the other, to screen the bees from the sun. Let these boards be seven feet seven inches in length, and nailed to the inside of the posts, and be well seasoned, that they may not shrink or gape in the joints.

c, c, are two splines of deal, to keep the boards even, and strengthen them.

Plate III. fig. 11. represents the back of the frame. *d, d, d, d*, are four strong boards of the same length with the frame, on which you are to place the boxes. Let the upper side of them be very smooth and even, that the boxes may stand true upon them ; or it may be still more advisable, to place under every pair of boxes a smooth thin board, as long as the boxes, and about a quarter of an inch wider. The bees will soon fasten the boxes to this board, in such manner that you may move or weigh the boxes and board together, without breaking the wax or resin, which for many reasons ought to be avoided. These floors must be supported by pieces of wood, or bearers *e, e*, &c. which are nailed from post to post at each end. They are likewise to be well nailed to the frame, to keep them from sinking with the weight of the boxes.

f represents the roof, which projects backward about seven or eight inches beyond the boxes, to shelter them from rain.

You have now only to cut niches or holes in the frame, over against each mouth or entrance into the boxes, at *h, h, h*, in fig. 10. Let these niches be near four inches long ; and under each you must nail a small piece of wood for the bees to alight upon.

The morning or evening sun will shine upon one or both ends of the frame, let its aspect be what it will : but you may prevent its over-heating the boxes, by a loose board set up between the posts, and kept in by two or three pegs.

The same gentleman, with great humanity, observes, that no true lover of bees ever lighted the fatal match without concern ; and that it is evidently more to our advantage to spare the lives of our bees, and be content with part of their stores, than to kill and take possession of the whole.

About the latter end of August, says he, by a little inspection through your glasses, you may easily discover which of your colonies you may lay under contribution. Such as have filled a box and a half with their works, will pretty readily yield you the half box. But you are not to depend upon the quantity of combs, without examining how they are stored with honey. The bees should, according to him, have eight or nine pounds left them, by way of wages for their summer's work.

The most proper time for this business is the middle of the day : and as you stand behind the frame, you will need no armour, except a pair of gloves. The operation itself is very simple, and easily performed, thus : open the mouth of the box you intend to take ; then with a thin knife, cut through the resin with which the bees have joined the boxes to each other, till you find that you have separated them ; and after this thrust a sheet of tin gently in between the boxes. The communication being thereby stopped, the bees in the fullest box, where most likely the queen is, will be a little disturbed at the operation ; but those in the other box, where we suppose the queen is not, will run to and fro in the utmost hurry and confusion, and send forth a mournful cry, easily distinguished from their other notes. They will issue out at the newly opened door ; not in a body, as when they swarm, nor with such calm and cheerful activity as when they go forth to their labours ; but by one or two at a time, with a wild flutter, and visible rage and disorder. This, however, is soon over ; for as soon as they get abroad, and spy their fellows, they fly to them instantly, and join them at the mouth of the other box. By this means, in an hour or two, for they go out slowly, you will have a box of pure honey, without a living bee in it to molest you ; and likewise without dead bees, which, when you harin them, are often mixed with your honey, and both waste and damage it.

Mr. White's boxes are very convenient, not only for taking away part of the honey, without breaking the combs, without killing any of the bees, or much disturbing them, but also on two other accounts : first, for feeding weak swarms, or such whose stock of provision is exhausted, and require to be fed to keep them alive ; the usual methods of feeding them with sugar and other substances being often ineffectual : and even honey is in some degree so also, for several reasons, but principally because the natural food of bees is not honey alone ; and whether bee-bread, or whatever else, is their food, they have it ready prepared for them, by adding a box to their store that was taken from them, or some of the colonies, in autumn ; for some of these boxes, full of combs, should be kept entire, and given them when their own store is exhausted. A colony of these boxes is also very conveniently, and with little trouble, cleared of moths, or other insects, that are pernicious or troublesome to the bees ; for the boxes may be taken away from the colony singly ; and after the moths, &c. are destroyed, may be immediately returned to the colony.

The indefatigable Mr. Wildman has obliged the world with the following method of taking the wax and honey, without destroying the bees :

Remove, says he, the hive from which you would take the wax and honey, into a room ; into which admit but little light, that it may at first appear to the bees as if it were late in the evening. Gently invert the hive, placing it between the frames of a chair, or other steady support, and cover it with an empty hive, keeping the side next the window of the empty hive raised a little, to give the bees sufficient light to get into it. While you hold the empty hive steadily supported on the edge of the full hive, between your side and your left arm, keep striking with your other hand all round the full hive from top to bottom, in the manner of beating a drum, so that the bees may be frightened by the continual noise from all quarters ; and they will, in consequence, mount out of the full hive into the empty

and leave the bees thus cut off from the rest of their companions for the space of half an hour or more. In this time, having lost their queen, they will fill themselves with honey, and be impatient to be set at liberty.

If, in this interval, you examine the box or boxes beneath, and observe all to be quiet in them, you may be confident that the queen is there, and in safety. Hereupon raise the back part of the hive or box so far, by a piece of wood slipped under it, as to give the prisoners room to come out, and they will return to their fellows: then lifting the box from off the colony, and turning it bottom upmost, cover it with a cloth all night; and the next morning, when this cloth is removed, the bees that may have remained in it will return to the colony. Thus you have a hive or box of honey, and all your bees safe.

Mr. Thorley adds, that the method he has pursued with great success for many years, and which he recommends to the public, as the most effectual for preserving bees in common hives, is incorporation, or uniting two stocks into one, by the help of a peculiar fume or opiate, which will put them intirely in your power for a time, to divide and dispose of at pleasure. But as that dominion over them will be of short duration, you must be expeditious in this business.

The queen is immediately to be searched for, and killed. Hives which have swarmed twice, and are consequently reduced in their numbers, are the fittest to be joined together, as this will greatly strengthen and improve them. If a hive which you would take is both rich in honey, and full of bees, it is but dividing the bees into two parts, and putting them into two boxes, instead of one. Examine whether the stock to which you intend to join the bees of another, have honey enough in it to maintain the bees of both: it should weigh full twenty pounds.

The narcotic, or stupefying fume, is made with the *fungus maximus*, or *pulverulentus*, the large mushroom, commonly known by the name bunt, puckst, or frog-cheese. It is as big as a man's head, or bigger: when ripe, it is of a brown colour, turns to powder, and is exceeding light. Put one of these pucks into a large paper, press it therein to two-thirds, or near half the bulk of its former size, and tie it up very close; then put it into an oven some time after the household bread has been drawn, and let it remain there all night: when it is dry enough to hold fire, it is fit for use. The manner of using it is thus:

Cut off a piece of the puck, as large as a hen's egg, and fix it in the end of a small stick slit for that purpose, and sharpened at the other end, which place so that the puck may hang near the middle of an empty hive. This hive must be set with the mouth upward, in a pail or bucket, which shall hold it steady, near the stock you intend to take. This being done, set fire to the puck, and immediately place the stock of bees over it, tying a cloth round the hives, that no smoke may come forth. In a minute's time, or little more, you will hear the bees fall like drops of hail into the empty hive. You may then beat the top of the full hive gently with your hand, to get as many of them as you can: after this, loosing the cloth, lift the hive off to a table, knock it several times against the table, several more bees will tumble out, and perhaps the queen among them. She often is one of the last that falls. If she is not there, search for her among the main body in the empty hive, spreading them for this purpose on a table.

You must proceed in the same manner with the other hive, with the bees of which these are to be united. One of the queens being secured, you must put the bees of both hives together, mingle them thoroughly, and drop them among the combs of the hive which they are intended to inhabit. When they are all in, cover it with a pucking or coarse cloth, which will admit air, and let them remain shut up all that night, and the next day. You will soon be sensible that they are awaked from this sleep.

The second night after their union, in the dusk of the evening, gently remove the cloth from off the mouth of the hive, (take care of yourself) and the bees will immediately fly forth with a great noise; but being too late, they will soon return; then inserting two pieces of tobacco-pipes to let in air, keep them confined for three or four days, after which the door may be left open.

Providence has ordained that insects which feed on leaves, flowers, and green succulent plants are in an insensible or torpid state from the time that the winter's cold has deprived them of the means of subsistence. Thus the bees, during winter, are in so lethargic a state, that little food

supports them: but as the weather is very changeable, and every warm or sunny day revives them, and prompts them to return to exercise, food becomes necessary on these occasions. Mr. White very judiciously observes, that a greater degree of cold than is commonly imagined to be proper for bees, is favourable to them in winter. If a sharp frost, says that experienced gentleman, continues for two or three months, without intermission, you may observe through your glass, that the bees are all this time closely linked together in clusters between the combs. If they are not altogether without motion, yet it is certain they stir not from their places, while the cold continues, and therefore are not at all.

A colony of bees therefore placed on the north side of a building, will waste much less of their provisions, than others which stand in the sun; for coming seldom forth, they eat little; and yet in the spring are as forward to work and swarm, as those which had twice as much honey in the preceding autumn. The owner should however examine their state in the winter, if he finds that instead of being clustered between the combs, they fall down in numbers on the stool or bottom of the hive, the hive should be immediately carried to a warmer place, where they will soon recover.

Mild winters are very injurious to bees in England; a small degree of warmth enlivens them, and then they eat and consume great part, and some winters all their stock of honey, which is necessary to them in a cold wet spring. The sunshine in winter entices them to go abroad, where, by a sudden shower of rain, or alteration in the degree of cold, they are disabled, and if obliged to rest, are soon killed. By these accidents, many swarms that were strong, and had large provisions of honey in autumn, are so weakened, and their stock of provision so much lessened, that they never recover so as to gather any valuable quantity of honey.

But when the weather is cold, and continues so through great part of the winter, they are not so liable to these accidents as in milder winters; for during the continuance of frosty weather they remain inactive, torpid, and almost motionless; and eat very little or no honey.

This appears to be the reason that bees thrive so much in some countries more than in others, that in other respects seem to be equally proper for them; and is probably one principal reason of bees thriving remarkably well in Poland, where the weather is not so changeable as in England, and the cold of their winters continue longer, and more uniformly.

Hence a method has been thought of to preserve bees in England, and prevent the waste of honey in winter, different from any of those hitherto mentioned.

At the usual time of the approach of winter, the hives are removed into a dark vault or cellar; where the bees being kept cold and dark, soon fall into a torpid state, and so continue throughout the winter, and till the flowers they feed upon begin to be disclosed. They are then removed to their summer situation, and enter upon their labours with great vigour and activity; and having a good stock left of the last year's provision, are in no danger of starving, or suffering much by a backward or unfavourable spring, by which other bees are often greatly injured.

The bees thus removed, are not in much danger from an excess of cold, as that may be moderated in the same manner as is done for preserving wine lodged in vaults or cellars in severe winters. The great difficulty seems to be to prevent the bees being too warm in mild winters, which might make them very uneasy and restless, as they are known to be when too much exposed to heat in summer. Some have proposed as a remedy for this, to place the hives in ice-houses; but this could be of service in a very few places only, and can never be of general use, if such a degree of cold was necessary, which probably it is not, as the trials that have been hitherto made of this method of disposing of bees in winter have succeeded; all their lives, and all their honey also, or much the greater part of it have been saved.

Should this method be found effectual upon full experience, it seems likely to be of more general use, than any other hitherto proposed; as it will without doubt be a means of greatly encreasing the quantity of wax and honey, where it shall be judiciously practised.

Most writers on bees have observed, that these insects are subject to a kind of purging in the spring, which is often fatal to the whole hive. Madam Vicat ascribes this

distemper to the honey being candied in the hive by the cold. But Columella describes it as an annual distemper which seizes them in the spring, when the spurge blossoms, and the elm discloses its seeds; for that the bees, being allured by the first flowers, feed so greedily upon them, that they surfeit themselves therewith, and die of a looseness, if they are not speedily relieved. He relates Hyginus's advising, in this case, to cover the bees with ashes of the fig-tree; and affirms, that being enlivened by the warmth of these ashes, the bees will revive in two hours, and go into a hive brought to them. Columella advises giving them rosemary and honey diluted with water. Aristomachus seems to have prescribed the most effectual cure, namely, to take away all the vitiated combs, that is, all the combs in which there are open cells appearing to have candied honey.

The authors of the *Maison Rustique*, impute this purging to the bees feeding on pure honey, which does not form a food sufficiently substantial for them, unless they have bee-bread to eat at the same time; and advise giving them a honey-comb taken from another hive, the cells of which are filled with crude wax or bee-bread.

The common practice is to feed them in the autumn, giving them as much honey as will bring the whole weight of the hive to near twenty pounds. To this end, the honey is diluted with water, and then put into an empty comb, split reeds, or, as Columella directs, upon clean wool, which the bees will suck perfectly dry.

The following directions given for this purpose in the *Maison Rustique*, seem to be very judicious. Replenish the weak hives in September, with such a portion of combs full of honey, taken from other hives, as shall be judged to be a sufficient supply for them. In order to do this, turn up the weak hive, after taking the precaution of defending yourself with the smoke of rags, cut out the empty combs, and put the full ones in their place, where secure them with pieces of wood run across, in such a manner that they may not fall down when the hive is returned to its place. The bees will soon fix them more effectually. If this method be thought too troublesome, set under the hive a plate of liquid honey, unmixed with water, with straws laid across it, and over these a paper pierced full of holes, through which the bees will suck the honey, without daubing themselves. This should be done in cloudy or rainy weather, when the bees stir least abroad; and the hive should be covered, to protect the bees from robbers, who might be allured to it by the smell of honey.

Another circumstance which may render it very necessary to feed the bees, is, when several days of bad weather ensue immediately after they have swarmed; for then, being destitute of every supply beyond what they carried with them, they may be in great danger of being starved. In this case honey should be given them in proportion to the duration of the bad weather.

Mr. Marshall, in his *Rural Economy of Norfolk*, gives the following account of a swarm of bees taking possession of a hive that had had its swarm destroyed by accident.

"I put a swarm of bees into a wooden hive, of a particular construction. They took it remarkably well, and in the course of the summer laid up an ample store. But the mildness of the autumn, and the length of the spring, were fatal to a principal part of the bees in the country; and to these among the rest. Nevertheless, through inattention, I let the hive stand in its place, with the empty comb in it.

Passing by it on the twenty-fourth of July, (the height of swarming-time this year) I saw several bees about the mouth of the hive; but in the evening they disappeared. Next morning they returned; and, at noon, were followed by a very large swarm, which took possession of the hive; and, in a few hours, began throwing out the dead, and clearing their new habitation; a work that employed them that and the ensuing day.

Perhaps this was a stray flight, which had settled upon some neighbouring tree; and the first were out-scouts, searching for a hollow tree, or a fissure in a rock.

But it is not enough to know how to manage bees in all seasons; it will be also requisite to know how to defend them from their enemies; among which hornets and wasps, and especially that species of wasps which are scarcely larger than bees, are very formidable; for they seize a bee loaded with honey. If this robbery is committed near the mouth of the hive, they carry off the bee to a place of greater safety. Their nests should therefore be carefully destroyed, by pouring plenty of boiling-water into them; for this is by much the safest method.

The field-mouse is an enemy to be carefully guarded against as soon as the cold begins to approach: for if it enters at that season, it makes dreadful havock. At first it destroys the lowest parts of the combs; but as the weather grows colder, and the bees more torpid, it ascends up the hive, and seizes on the richest treasure: nor does the evil end here: for other bees, smelling the honey spilt by the mouse, fall upon the hive, and rob it of what remained; or as soon as the warm weather returns, and the bees stir about, they are sometimes so disgusted at the havock made by the mouse, that they desert the hive. The only way to guard against this, is to prevent its entering into a hive. Whilst the bees continue in their vigorous state, it dares not attack them: therefore, as soon as the cold approaches, the entrance to the hives should be lessened.

Bees may themselves be reckoned enemies to bees: for they sometimes wage cruel wars against each other.

Their fighting and plundering one another ought chiefly to be imputed, as Mr. Thorley observes, either to their perfect abhorrence of sloth and idleness, or to their insatiable thirst for honey: for when, in spring or autumn, the weather is fair, but no honey can be collected for plants, and is to be found only in the hives of other bees, they will venture their lives to get it there.

Dr. Warder assigns another cause of their fighting, which is, the necessity that the bees are reduced to when their own hive has been plundered, at a season when it is too late for them to repair the loss by any industry in the fields.

Sometimes one of the queens is killed in battle. In this case, the bees of both hives unite as soon as her death is generally known among them. All then become one people: the vanquished go off with the robbers, richly laden with their own spoils, and return every day, with their new associates, to pillage their own habitation. This causes a throng unusual for the season, at the door of the hive they are plundering; and if the owner lifts it up at night, when all are gone home, he will find it empty of inhabitants; though there perhaps will remain in it some honey, which he takes as his property.

When two swarms take flight at the same time, they sometimes quarrel, and great numbers are destroyed on both sides, till one of the queens are slain. This ends the contest, and the bees of both sides unite under the surviving sovereign.

Robbers make their attacks chiefly in the latter end of July, and the month of August. They appear to act with caution at first, and to procure themselves an entrance by stealth; not pitching boldly like the native bees, and then entering at once in at the door. If they are encouraged by success, they return in greater parties, sometimes all the bees of a hive, and endeavour to force that entrance which they sought before with so much caution. They come in such numbers, as frequently to make those who are not acquainted with these scenes, mistake them for new swarms: but the number of dead bees strewed on the ground, soon convince them of this error. Columella advises to kill the queen, if possible; but the most effectual way to prevent the loss of bees, as well as of honey, occasioned by these robberies, is, early in the autumn, to lessen the entrance into the hive, as before directed, so as to leave room for only two or three bees to pass a breath.

In the third class of enemies to bees is a small caterpillar, termed the wax-worm, or wax-moth, because of the havock it makes on wax. It is tender in its frame, unarmed and defenceless; and yet can subsist itself in the midst, and at the cost, of the most numerous hive. A few of these little caterpillars will destroy and break to pieces the combs of a hive, build up new edifices for lodging themselves in it, and finally force the bees to quit the place.

This insect is of the species of the false-moth, and is extremely nimble. It is enough for it to get into a hive unawares. It runs so very swiftly, that it passes unperceived, and slides into some narrow place between the combs, perhaps inaccessible to bees, there to lay its eggs in security. This done, it makes its escape as well as it can. From each of these eggs proceeds a caterpillar, which escapes certain death merely by its extreme smallness, and the quickness with which it spins and wraps itself in a covering sufficient to secure it from all harm. This covering, or tube, is glued to the wax which the caterpillar feeds on, and this insect lengthens the tube as it eats the wax, till at last it shuts itself up, in order to be transformed into a chrysalis. Several caterpillars, and consequently several moths, must proceed from the eggs which the males and females engender. Probably the bees destroy great num-

numbers of the moths: however, if a single female has an opportunity to lay her eggs, she is so exceedingly prolific, that this second brood may quite overspread the hive. If one of the impregnated females escapes out of the hive by means of her great nimbleness, she seeks out another hive, in which she spreads the same source of mischief.

The only method of destroying these pernicious insects is to take away the infected hive; and after clearing it from the moths, restore it to the proper owners, who will now work with greater diligence and resolution.

The next particular necessary to be known, is how to separate the honey from the wax. In order to this, the combs should be laid in a place perfectly secure from the access of bees; for otherwise the bees would not only carry off much honey, but also be extremely troublesome by stinging the people at work. It is proper to burn cow-dung, or rotten hay, at the doors and windows of this place; because the smell of the smoke arising from thence is so disagreeable to the bees, that it will drive them away. If any bees remain in the comb, they should be brushed off with the wing of a fowl into a tub of water, and being afterwards dried in another place, they will fly back to their hive. If the combs are taken out of the hive before the end of autumn, there are generally young bees in them. The parts of the combs in which these are should be laid aside, for they would give a bad taste to the honey. The bee-bread must also be separated, and both should be melted with the wax.

Before the combs are laid to drain out their honey, they should be carefully cleaned of every sort of filth, or insects. The crust with which the bees cover the honey in them should then be pared off with a sharp, thin, broad knife, and the combs themselves should be divided through the middle, in such manner as to render the cells open at both ends, that the honey may flow the more freely out of them. The combs should be laid in this state on sieves, or some other contrivance which will afford the honey a free passage. It will run quite clear; and the honey thus obtained should be kept by itself, as being the purest and best.

The combs, which are but partly filled, and also those that were full and have done running, are broken by hand, and the honey in them is squeezed out. Some put the broken combs into a strong bag, and then use a press to squeeze the honey out of them; and even warm the broken combs with the help of fire: but neither of these last consider that, in both these ways, much of the wax passes through the bag with the honey, and thus the wax being of greater value than the honey, the owner sustains a loss in that respect, besides that his honey becomes the less valuable, in proportion to its being less pure. It is true, that great part of the wax thus mixed with the honey soon rises to the surface, and may be taken off, especially after the honey is grown hard.

The makers of mead need not be extremely solicitous about separating the honey so very perfectly from the wax, because, by washing the wax in cold water, the honey will dissolve in the water, and the wax being strained from it by running the water through a coarse cloth, neither bad taste nor impurity will be communicated by it to the water, which may afterwards be used for making mead. The wax that has been skimmed off the honey separated by pressure, should be washed in the same manner; because, by this means, no part of the wax will be lost.

The goodness and flavour of honey depend on the fragrance of the plants from which the bees collect it: and hence it is that the honey of different places is held in different degrees of estimation. Mr. Marshall, in his Rural Economy of Norfolk, doubts the evil effect of buck on honey, until it be proved, notwithstanding the present received opinion; and thinks that the inferior quality of honey produced in that country may be attributed to the heath, which is well known to afford much honey but of an inferior quality. This he remarks also in his Rural Economy of Yorkshire, which he says may be called a bee-country; especially the Morelands and the northern margin of the Vale; where great numbers of bees have been usually kept; and great quantities of honey collected; chiefly from the flowers of the heath, which afford an abundant supply; but the produce is of an inferior quality; brown and strongly flavoured.

In hives situated between the heaths and the cultivated country, a striking contrast is observable between the spring and the autumnal combs. The former gathered wholly from the meadows, pasture-lands, trees, and cultivated

crops; the latter entirely from the flowers of the heath; none of the species of which begin to blow until late in the summer. The combs of the former will be nearly white as snow: and the honey limpid almost as the purest oil. Those of the latter brown: and the honey they yield of the colour and consistency of melted rosin. This difference is most striking when the hive is carried in autumn, from the lower parts of the marginal heights, into the Moreland dales, to be filled up with honey; a practice which, singular as it may appear, has been followed with success.

In the winter of 1782-3, a general mortality took place among the bees of this country. Many bee-keepers lost their whole stock. I remember to have seen in the spring of 1783, twelve to fifteen empty stones in one garden without a single surviving hive.

But the universality of the destruction, uncommon as it was, being such as no one can remember, was not so remarkable as the manner in which it was effected. The bees were observed to dwindle away, by degrees; though they had plenty of honey in their hives; at length vanishing: while still, perhaps, a considerable quantity of honey remained unexhausted.

A man who has paid some attention to bees, and whose ideas are frequently well grounded, was of opinion that the effect was entirely owing to the want of a succession of young bees; under a supposition that the year preceding had not been a breeding year; and that the bees which dwindled away in the spring were the old bees dying of age.

There may be some truth in this opinion; the unusually backward, and extremely wet spring and summer of 1782, might check the breeding of young bees; but it is unlikely that it should wholly put a stop to it; and that not one hive in ten should have bred a single bee. For under this argument the young ones, though few, would, with an ample store of honey, have survived.

In the course of the spring of 1783, an incident led me to a theory which seems to explain the phenomenon more fully.

Being attentive to a female fallow which was in blow, I observed that bees were equally busy among its flowers, as they were among the male catkins of a neighbouring tree.

This induced me to consider the nature of the materials they collect, and to reflect on whether the different parts of generation, even in hermaphrodite flowers may not afford them distinct materials. Honey, it is well understood, is collected from the nectarium. Wax may well be considered as a collection of the viscid mucus of the pistillum; as bee-bread appears to be merely an aggregation of the farina of the stamen.

It is well understood by bee keepers in general, and is asserted by Wildman himself, that bees cannot live without bread. That they cannot exist with pure honey alone, is, I believe, well ascertained. But honey which has been pressed hard from a comb containing bee-bread as well as honey, is considered as a safe and certain relief to them when their own stores are exhausted.

Admitting that bees require bread, as well as honey, to support them in winter; and admitting that bee-bread is a collection of the staminate farina of flowers; the phenomenon under notice is easily explainable.

It is well known, that flowers are tenacious of their parts of generation in a rainy season; exposing them with caution. Nor is it mere exposure that fits the stamina for the purpose of the bee. The anthers must be burst by the sun, before the bee can load its thighs with the contained farina; which being exposed, is liable to be washed away, or shook down, by the first heavy shower. Hence the collection of bee-bread, in a moist showery season, must be very precarious and inconsiderable.

But the collecting of wax and honey depends less on the weather. For the flower once open, the bee has free access to the nectary and pistil, whose productions are less liable to a shower than is the farina. Besides, it is, I believe, a fact which is not doubted, that bees collect honey from what are, perhaps, improperly called honey-dews, as well as from flowers. That which is made early in the year is also preferred to what is collected in the latter end of the season.

In order to obtain the wax in a pure state, what remains of the combs after separating the honey, together with the combs which contain bee-bread and young bees or maggots, is put into a copper with a sufficient quantity of clean water, which is made to boil over a slow fire, and stirred frequently with a stick. When the wax is melted, it is

run through bags, which are put into a press, to separate the wax perfectly. The wax runs from the press into a vessel placed underneath, with some water in it, to prevent the wax from sticking to it. What remains after the pressure may be again boiled in water, in order to obtain more wax from it: and this should be repeated by slow boilings, rather than by boiling it strongly at once.

When all the wax is thus separated from the dregs, it is again melted in water, over a very gentle fire, and skimmed clean whilst any scum arises. It is then poured into vessels suited to give it the desired form, after previously putting into them a little water, to keep the wax from sticking to them. These vessels are then carried into a place where the wax may cool gradually. It is found that, the larger the cakes of wax are, the better the wax keeps, and the higher price it brings; also, that the more gentle it has been boiled, the better it likewise is: for too hasty boiling renders it hard, and this increases the difficulty of bleaching it. Whatever filth sticks to the bottom of the cake, is scraped off with a knife.

We shall conclude this article with a few directions for purchasing bees; which should always be done in the spring, as the dangers of the winter are then over. The summer is an improper time for buying them, because the heat of the weather then softens the wax, and thereby renders the combs liable to break, if they are not very well secured. The honey too, being then thinner than at other times, is more apt to run out of the cells, which is attended with a double disadvantage, namely, the loss of the honey, and the daubing of the bees, whereby many of them may be destroyed. A first and strong swarm, may indeed be carried away in the night after it has been hived.

The hive should be full of combs, and well stored with bees. The purchaser should examine the wax, in order to know the age of the hive. The combs of a year old are white; those of two years are dark coloured, or yellow; and where the combs are black, the hive should be rejected; because old hives are most apt to be infected with the moth, and most liable to other accidents. For this reason, the state of the combs should be examined as high up as possible; because the lower parts of the combs may have been cut off, and renewed in the preceding summer. It sometimes, though rarely, happens, that two queens continue to govern separately in the same hive; and in this case a large comb forms the barrier. Such hives should be rejected, because there is not in them that harmony which is necessary for the success of the bees.

In order to judge of the state of the hive, it may be raised a little in the evening, so as to admit a more than usual degree of cold; for this will drive the bees to the top of the hive, and so benumb them, that the next morning there will be no danger of their stinging. If any such danger does appear, a pot of lighted charcoal, with some linen-rags upon it, may be got ready, and held under the hive whilst it is pulled back in order to be examined.

We may also judge of the thriving state of the hive by the following appearances. Bees which are in good condition will get into the fields early in the morning, return loaded, enter boldly, and not come out of the hive in bad weather; for when they do, this indicates that they are in great want of provisions. They are alert on the least disturbance; they preserve their hive free from all filth, or dead nymphs or bees; they are ready to assist the bees which return loaded from the fields, and to defend the hive against every enemy that dares to approach: they make a continual humming noise, which increases on the least touch. Indeed, by the loudness of the humming, we may judge of the strength and progress of the hive, and therefore this should be frequently noticed, to enable us to form the better judgment of the present state the bees are in. *Columella, lib. IX. Maison Rustique, tom. I. Memoires, &c. de la Societe de Bern, Ann. 1764. Reaumur's Memoires pour servir à l'Histoire Naturelle des Insectes, tom. V. Thorey's Enquiry into the Nature, &c. of Bees. Warder's Monarchy of Bees. White's collateral Bee-boxes. Milp's Essay on the Management of Bees.*

BEECH, the name of a well known tree, and of which some planters suppose there are two distinct species: calling the one the mountain or wild beech, and the other the common beech. They also say, that the wood of the former is whiter than that of the latter; but Mr. Miller assures us that there is only one species of this tree, and that the difference in the colour of the wood arises from the difference in the soils.

This tree is propagated by sowing the mast, which may be done at any time from October to February, only observing to secure the seeds from vermin when early sown; and, if this be carefully done, the sooner they are sown after they are fully ripe, the better: a small spot of ground will be sufficient for raising a great number of these trees from seed; for if the plants are come up very thick, the strongest of them should be drawn out the autumn following, that those left may have room to grow; so that a seed-bed, carefully managed, will afford a three year's draught of young plants, which should be planted in a nursery, and, if designed for timber trees, at three feet distant row from row, and eighteen inches asunder in the rows.

But if they are designed for hedges, to which the tree is very well adapted, the distance need not be so great: two feet row from row, and one foot in the rows, will be sufficient. In this nursery they may remain two or three years, observing to dig up the ground between the roots, at least once a year, that their tender roots may the better extend themselves every way: but be careful not to cut or bruise their roots, which is injurious to all young trees; nor should you ever dig the ground, in summer, when the earth is hot and dry; for by letting in the rays of the sun to the roots, the young trees are often destroyed.

This tree will grow to a considerable stature, though the soil be stony and barren, as also upon the declivities of hills and chalky mountains, where they will resist the wind better than most other trees; but then the nurseries for the young trees ought to be made upon the same soil; for if they are raised on good ground, and in a warm exposure, and afterwards transplanted into a bleak barren situation, they seldom thrive. The nursery should therefore be made upon the same soil, where the plantation is intended, and the plants drawn annually to extend the plantation.

This tree is very proper to form large hedges to surround plantations, or wilderness quarters; and may be kept in a regular figure, if sheared twice a year; especially if they shoot strong; in which case, if they are neglected but a season or two, it will be very difficult to reduce them again.

The shade of this tree is very injurious to most sorts of plants which grow near it, but is generally believed to be very salubrious to human bodies.

It delights in a chalky or stony ground, where it generally grows very fast; the bark of the trees in such land is clear and smooth, and although the timber is not so valuable as that of many other trees, yet as it will thrive on such soils, and in such situations where few better trees will grow, the planting of them should be encouraged, especially as the trees afford an agreeable shade, and the leaves make a fine appearance in summer, and continue green as long in autumn as any of the deciduous trees; therefore in parks, and other plantations for pleasure, this tree deserves to be cultivated among those of the first class, especially where the soil is adapted to it. *Miller's Gard. Dict.*

The timber is of great use to turners for making trenchers, dishes, trays, &c. and also to carpenters for making stools, bedsteads, &c. Shipwrights likewise often use it for the keels of ships; and it is esteemed the best wood for firing. The thin lamina, or scale of the wood, commonly called paste-board, is used in making band-boxes, hat-cases, &c.

Beech-wood is well known to be subject to worms which soon destroy it. This worm is supposed to feed up on the sap remaining in the wood after it is cut into scantlings, and worked up for use. If therefore the sap, can, by any means, be extracted, the wood will be much less subject to decay. Upon this principle, a correspondent of the authors of the *Museum Rusticum* greatly improved the wood, by laying it a reasonable time in a pond, and afterwards drying it in the shade; by which means the timber when applied to use, was at least as good, and as durable as elm. He adds, that by boiling the wood intended for smaller works, such as bowls, trenchers, chairs, &c. two or three hours in a copper filled with water, all the sap will be extracted, the wood will work pleaster, be more beautiful when finished, and last, without comparison, longer. *Museum Rusticum, vol. II. p. 135.*

BEECH mast, the seed of the beech-tree.

This mast is very good for feeding swine; so that in some counties of England, where there are large woods of beech trees, the hogs are fed for months together on the mast only. They thrive prodigiously on this food only, so that many porkers are killed in a year fatted with beech-mast, with-

out the assistance of any other food. It is, however, the better way to take them up, and give them either pollard, barley-meal, or pease, for a month or five weeks, when they will be fit for the tub.

But beech-mast, like acorns, are apt to give the hogs a distemper called the garget; which may be effectually prevented, if a few pease or beans, moistened with water, and sprinkled over with antimony finely powdered, be given them every other day for a fortnight or three weeks. *Museum Rusticum*, vol. I. p. 474.

BEES-NEST, or *birds-nest*, the same with wild carrot. See the article *WILD CARROT*.

BEESTINGS, the first milk taken from a cow after calving.

If this milk be not taken away clean from the cow upon her first calving, it will often make the cow's milk to dry away. Nor should the beestings be given to the calf, as it is very apt to surfeit. *Lisle's Husbandry*, vol. II. p. 143.

BEETLE, a wooden instrument in the form of a mallet, but much larger, used in driving piles, wedges, hedge-stakes, &c.

BEETLE, is also the name of a flying insect, of which there are a great variety of species; but they have all of them cases over their wings to defend them from hard bodies, which they often meet with when they dig holes in the ground, or gnaw rotten wood with their teeth, to make themselves houses or nests. When they fly they fill the air with a humming noise, and, perhaps, greater than that of any other insect. There are different sorts of beetles, some being large with horns, and others small, and without horns.

BEEVES, a general name for oxen, or black cattle in general.

BEHEN, a species of chickweed, frequently called spatling-poppy. See *CHICKWEED*.

BENT-grass, a species of grass common in pasture grounds; there are several sorts of this grass, particularly that called fine bent, for the gathering the seeds of which the Society offered a premium. We have given a figure of one of the species of bent-grass, on Plate III. fig. 11.

BERBERRY. See *BARBERY*.

BERE, or *bear*, a species of barley. See the article *BARLEY*.

BERNE-MACHINE, the name of an engine for rooting up trees, invented by Peter Sommer, a native of Berne in Switzerland.

A model of this machine was sent by the Berne Society to the Society for the Encouragement of Arts in London, and from this model the drawing on Plate IV. fig. 1. was made. The engine consists of three principal parts, the beam, the ram, and the lever. The beam A B C, of which only one side is seen in the figure, is composed of two stout planks of oak of three inches thick at least, and separated by two transverse pieces of the same wood at A and C, about three inches thick. These planks are bored through with corresponding holes, as represented in the figure, to receive iron pins, upon which the lever acts between the two sides of the beam, and which are shifted higher and higher, as the tree is raised, or rather pushed out of its place. The sides are well secured at top and bottom, by strong iron hoops.

The iron pins on which the lever rests, should be an inch and a quarter, and the holes through which they pass, an inch and a half in diameter. The position of these holes is sufficiently indicated by the figure.

The foot of the beam, when the machine is in action, is secured by stakes represented at G, driven into the earth.

The ram D, which is made of oak, elm, or some other strong wood, is capped with three strong iron spikes, represented at f, which takes fast hold of the tree. This ram is six or eight inches square, and a slit is cut lengthwise through the middle of it, from its lower end at L, to the first scule a, in order to allow room for the chain g h, to play round the pulley K, which should be four inches thick, and nine inches in diameter. This ram is raised by means of the chain g h, which should be about ten feet long, with links four inches and three quarters in length, and an inch thick. One end of this chain is fastened to the top of the beam at C, while the other, after passing through the lower part of the ram, and over the pulley K, terminates in a ring or link represented fig. 3. the two ears m, n, of which serve to keep it in a true position between the two planks of the beam. In this ring the hook P is inserted.

The hook is represented in profile, fig. 2. where P is the

part that takes hold of the ring. But it must be observed, that the parts of this machine, represented in fig. 2, 3. are drawn on a scale twice as large as the whole engine, fig. 1.

The hook F fig. 2. should be made of very tough iron, as well as the handle D, and the arch E c. This handle should be two inches thick at z, where it joins to the hook, and the thickness gradually lessen by degrees up to the arch, which need not be more than half an inch thick.

On each side of the pin z, is a semi-circular notch, x, y, which rests alternately on the pins, when the machine is worked. The hole D, and the arch E c, serve to fix a long lever of wood E F, fig. 2. by means of two iron pins; and by this contrivance the lever is either raised or depressed at pleasure, in order to render the working of the machine easy in whatever part of the beam the lever may be placed: for without this contrivance the extremity of the lever E F, would, when the handle d F was near the top of the beam C, be much higher than men standing upon the ground could reach. It must, however, be remembered that the lever is often shortened by this contrivance, and consequently its power lessened.

The machine is worked in the following method: it is placed against a tree, in the manner represented in the figure, so that the iron spikes at f may have hold of the tree, and the end of the beam A be supported by stakes represented at G. The iron handle, fig. 2. is placed in the opening between the two planks of the beam, and the wooden lever fixed to it by means of the iron pins already mentioned. The hook F takes hold of the chain, and one of the iron pins is thrust into the outer row of holes, by which means the outer notch x will rest on the pin, which will now be the center of motion; and the end of the lever E, fig. 1. being pressed downwards, the other notch y, fig. 2. will be raised, and at the same time the chain, and consequently the ram. The other iron pin is now to be thrust into the hole in the inner row, next above that which was before the center of motion, and the end of the lever E, fig. 1. elevated, or pushed upwards, the latter pin on which the notch y rests, now becoming the center of motion. By this alternate motion of the lever, and shifting the pins, the chain is drawn upwards, over the pulley K, and consequently the whole force of the engine exerted against the tree. There is a small wheel at L, in order to lessen the friction of that part of the machine.

From this account the reader will very easily perceive that the machine is nothing more than a single pulley, compounded with a lever of the first and second order; and therefore its power may be easily computed from the nature of the pulley and lever.

It must, however, be remembered, that as the push of the engine is given in an oblique direction, it will exert a greater or lesser force against the horizontal roots of the tree in proportion to the angle formed by the machine with the plane of the horizon; and that the angle of 45° is the maximum, or that when the machine will exert its greatest force against the horizontal roots of the tree.

M. N. E. Tschanner, secretary to the Berne Society, observes, in a letter sent to the Society for the Encouragement of Arts, &c. in London, and dated Berne, Jan. 10th, 1763, that by repeated experiments with this machine, he has found that the chain g h, is so far from giving an additional power, that it hinders the play and effect of the engine by its friction; and that when the ram presses strongly against the beams, the chain is squeezed between the beams so as to render the upper holes useless, and prevents the machine from being worked out to its full length; in consequence of which it is obliged to be removed from its first place, and fixed again anew; which necessarily occasions a loss of time. He also found that the ram was too short. He has therefore taken away the chain, and lengthened the ram four feet.

The inconvenience of the chain was immediately seen by the Society for the Encouragement of Arts, and therefore the machine at large made by their directions, was constructed without it. The ram moved between the two cheeks of the beam, and was pushed up by the alternate motion of the lever. And that the force of the machine might not be lessened by the removal of the chain, the lever was made of twice the length of that in the Berne model.

It will be very readily granted that an engine constructed in this manner will be very useful in saving the labour of men; though very inadequate to the task intended, that of throwing down trees. For it sufficiently appeared from experiments made by the committee of mechanics, that trees

above

above sixteen inches diameter, especially of oaks or elms, cannot be thrown down with this engine, without the assistance of cutting their roots.

BIENNIAL *plants*, such as continue two years.

BIG, the same with bere, or square barley. See the article BARLEY.

BIGGE, a pap, or teat.

BILL, an edged tool used by husbandmen in cutting bushes, &c. It is a kind of hatchet with a hooked point, and a handle either shorter or longer, according to the various uses for which it is intended.

BIN, or BINN, a place where corn, &c. is deposited.

BIND-WEED, called by some *with-wind*, *dodder* or *devil's guts*, also *boggar-weed*, a troublesome weed, of which there are two species, the smaller and the greater.

The first, or smaller bind-weed, commonly called gravel bind-weed, is very common upon dry banks, and in gravelly ground in most parts of England, and is generally a sign of gravel lying near the surface. Its roots penetrate very deep into the ground, whence it is in some countries called devil's guts. It is a very troublesome weed both in gardens and fields.

The second or greater bind-weed, is also a troublesome weed; but in an open clear spot of ground, where the plants are constantly hoed down for three or four months, they may be effectually destroyed; for when the stalks are broken or cut, a milky juice flows out, by which the roots are soon exhausted, and decay; but as every part of the root will grow, this circumstance renders it a troublesome weed to destroy, where its roots are intermixed with those of other plants. *Miller's Gard. Dict.*

Mr. Lisle, after observing that he believes bind-weed propagates itself in pasture grounds chiefly by its seeds, and by its roots in arable land, because it seems to flower too late in corn, to seed before the corn is cut, thinks the reason why it is most apt to multiply in clayey soils, is because such ground being, in the common practice, ploughed only in winter months, after wheat, for other crops, as barley, pease, or oats, and not till about September for winter vetches; this tillage cannot destroy the roots or seeds of weeds like the summer fallows for wheat; but, on the contrary, promotes their increase, particularly from the off-sets, or joints of the roots. "I have known, says he, in this case, clay-land folded for barley, and particularly that part of it which, waiting for the folds going over it last, was latest fallowed, bring up such an increase of with-wind, that, though the spring and summer had been very dry, every stem of barley had a with-wind round it. As the fold brought up a crop of this corn, it brought up with each plant its enemy, which would eat it out, pull it down before it could ripen, and thereby prevent the filling of the grain. The crop is also greatly hazarded here, after it is cut, from the danger it must run by laying in swarth, till this weed is withered before it can be carted. Again, near the end of the first summer, after the first year of a crop of hop-clover, which I fed, that is about the beginning of August, I fallowed the ground for wheat, then dunged the fallows, and sowed the wheat before Michaelmas. I had a very good crop of wheat; but a with-wind came up to every plant; so that had it been a wet and cold summer, instead of a hot and dry one, as it chanced to be, my corn would have been pulled down and lodged while green in the ear, and in the milk, and could not then have filled in body and flour, but must have been of the nature of blighted corn. The increase of the with-wind here was, without doubt, occasioned by laying down this ground only to one summer seed after the hop-clover was sown, when it had borne three or four crops of summer corn after its wheat crop; for, by the winter ploughing as I intimated before, the off-sets of the roots of weeds, and their seeds, were propagated. I could not conveniently destroy these roots or seeds by giving the ground a seasonable summer fallow in the beginning of June; because I should then have lost the fruits of my hop-clover crop, by ploughing it in at the beginning of the first summer: though this would have contributed much to the killing of the with-wind: whereas, by delaying the fallowing three months longer, viz. to the beginning of August, when the sun had lost its strength to burn up the roots and malt the seeds, and it was too late for the ground to lie long to a fallow, the dung laid on the fallows, gave new life to the roots and seeds." *Lisle's Husbandry*, vol. II. p. 303.

BIRCH, the name of a tree so well known as to need no description. This tree is not much esteemed for its

wood, but however it may be cultivated to advantage upon barren land, where better trees will not thrive; for there is no ground so bad, but this tree will thrive in it; for it will grow in any moist springy land, or in dry gravel or sand, where there is little surface: so that upon ground which produced nothing but moss, these trees have succeeded so well, as to be fit to cut in ten years after planting, when they have been sold for near ten pounds per acre standing, and the after-produce have been considerably increased. And as many of the woods near London, which were chiefly stocked with these trees, have of late years been grubbed; so the value of these plantations have advanced in proportion. Therefore those persons who are possessed of such poor land, cannot employ it better, than by planting it with these trees, especially as the expence of doing it is not great.

The best method to cultivate this tree, is to furnish yourself with young plants from the woods, where they naturally grow, and are generally found there in great plenty; but in places where there are no young plants to be procured near, they may be raised from seeds, which should be carefully gathered in the autumn, as soon as the scales under which they are lodged begin to open, otherwise they will soon fall out and be lost: the seeds are small, so should be not buried deep in the ground. The autumn is the best season to sow them; and in a shady situation, as the plants will thrive better than when they are exposed to the full sun; for in all places where there are any large trees, their seeds fall, and the plants come up well without care; so that if the young plants are not destroyed by cattle, there is generally plenty of them, in all the woods where there are any of these trees. These wild plants should be carefully taken up, not to injure the roots. The ground where they are to be planted, will require no preparation; all that is necessary to be done, is to loosen the ground with a spade or mattock, in the places where the plants are to stand, making holes to receive their roots, covering them again when the plants are placed, closing the earth hard to their roots. If the plants are young, and have not much top, they will require no pruning; but where they have bushy heads, they should be shortened, to prevent their being shaken and displaced by the wind. When the plants have taken root, they will require no other care, but to cut down the great weeds which would over-hang the plants, being careful not to cut or injure the young trees. This need not be repeated oftener than twice in a summer the two first years, after which time the plants will be strong enough to keep down the weeds, or at least be out of danger from them.

These may be planted any time from the middle of October, till the middle of March, when the ground is not frozen; but in dry land the autumn is the best season, and the spring for moist. The distance which they should be planted, is four feet square, that they may soon cover the ground, and by standing close they will draw each other up; for in situations where they are much exposed, if they are not pretty close, they will not thrive so well.

If the plants take kindly to the ground, they will be fit to cut in about ten years; and afterwards they may be cut every seventh or eighth year, if they are designed for the broom-makers only; but where they are intended for hoops, they should not to be cut oftener than every twelfth year.

The broom-makers are constant customers for birch, in all places within twenty miles of London, or where it is near water-carriage: in other parts the hoop-benders are the purchasers; but the larger trees are often brought by the turners, and the wood is used for making ox-yokes, and other instruments of husbandry.

In some of the northern parts of Europe, the wood of this tree is greatly used for making of carriages and wheels, being hard and of long duration. In France it is generally used for making wooden shoes. It likewise makes very good fuel.

In some places these trees are tapped in the spring, and the sap drawn out to make birch-wine, which has been recommended for the stone and gravel, as is also the sap unfermented. The bark of the birch-tree is almost incorruptible. In Sweden, the houses are covered with it, where it lasts many years. It frequently happens, that the wood is entirely rotten, and the bark perfectly sound and good. *Miller's Gard. Dict.*

The best method of obtaining the sap of the birch-tree for

for making wine, &c. is to bore a hole slanting upwards with a middle-sized augre to a moderate depth in the tree, and to fasten a bottle to the orifice, by which means a large quantity of the sap may be speedily procured. Or many gallons in a day may be gathered from the boughs of the trees by cutting them off, leaving their ends fit to go into the mouths of bottles, and so by hanging many bottles on several boughs, the liquor will distil into them very plentifully.

The season for this work is from the end of February to the end of March, whilst the sap rises, and before the leaves shoot out from the tree; for when the sap is forward, and the leaves begin to appear, the juice, by a long digestion in the branch, grows thick and coloured, which before was thin and limpid. Nor will the sap distil either in the night, or in cold weather while the north and east winds blow; but very well and freely, when the south-west winds blow, or the sun shines warm.

The liquor is best that proceeds from the branches having been a longer time in the tree, and thereby better digested, and acquired more of its flavour than if it had been extracted from the trunk. *Mortimer's Husbandry*, vol. II. p. 406.

In order to have enough of this liquor to set about making wine with it, many trees should be tapped at the same time, so that a sufficient quantity of sap may be obtained in a few days; for it will not keep long, without a tendency to putrefaction. To prevent this, some authors advise setting that which is first drawn in bottles, or other proper vessels, in the sun, till the rest be ready, and to put into it a hard toast of rye-bread cut thin, to make it ferment. But as it is necessary to mix with this juice either sugar or raisins, in order to give it a body, to enable it to undergo a regular fermentation, which alone can render it fit for keeping, and for want of which it is, that this wine is so apt to burst the bottles into which it is put, that first fermentation will certainly be found hurtful. When therefore the husbandman has not a sufficient number of trees to obtain sap enough for his purpose in two or three days, the most advisable way will be to put the sap into very sweet vessels, and place them in a cool cellar; for it will keep there perfectly sound, for a much longer time, especially if it be covered with oil, or bunged up close.

The proportion of sugar may be varied according to the taste and intention of the brewer: but, in general, a pound of sugar is thought to be the proper allowance for a gallon of this liquor. The sap and sugar must be thoroughly united by a heat just sufficient to make them boil; but the long boiling, which is generally advised, can answer no good purpose: on the contrary, it will render the liquor less disposed to ferment kindly, and likewise deprive it of a considerable part of the peculiar fragrance and flavour of the tree from whence it was taken. It should therefore be carefully remembered, that the sole purpose of boiling this liquor is, to make a thorough dissolution of the sugar in it. Some people substitute honey instead of sugar; in this case a quart of honey is esteemed equal to a pound of sugar. With regard to various spices ordered by different writers, they must be left to the taste and opinion of the maker.

It is generally found necessary in order to ferment this liquor, to put into it a little yeast, a bit of dough, or thin toast of leavened bread; after which it is treated in all respects like other vinous liquors. See the articles FERMENTATION and WINE.

It is said, that in the North, where large birch and plane trees are frequent, their sap is obtained in such plenty as to be used for brewing, instead of water, and that it makes equally strong beer with much less malt. Dr. Tong, in the Philosophical Transactions, N^o 46. says, that one bushel of malt brewed with this liquor will make as good ale as four bushels with common water. He thinks the sap of the sycamore the best for brewing; because it is very sweet, and, at the same time, very wholesome.

BIRDS FOOT TREFOIL, or the Lotus Corniculatus of Linnaeus, does, notwithstanding the dryness of a season, flourish in a singular manner, in the most exposed situation. On bowling-greens and mown lawns, it is almost the only green herbage left, (the daisy excepted) variegating their stone-coloured surfaces, in some instances, beautifully. In meadow and pasture grounds it is abundant. Its very strong deep tap root is evidently the cause of its thus resisting drought. Might not a productive va-

riety of this plant be cultivated with profit in dry situations? *Marshall's Rural Economy of the Midland Counties*, vol. II.

BIRD-GRASS, or FOWL-MEADOW-GRASS, a very excellent grass imported from Virginia, by the late Peter Wych, Esq. and has been cultivated with success by Mr. Roque. The Rev. Dr. Elliott, of New-England, in his Essays on field-husbandry, tells us, that it acquired this odd name from its being brought into a piece of poor meadow at Dedham, by ducks and other wild water-fowl. We have given a figure of this valuable grass on Plate IV. fig. 4.

As Mr. Roque is the only person that has successfully cultivated this species of grass, we shall give our readers his own account of it, which he sent in a letter to the Society for the Encouragement of Arts, &c.

"In the month of March, 1764, I received from the late Peter Wych, Esq. the chairman of the committee of agriculture in the Society for the Encouragement of Arts, &c. an ounce and a half of the seed of a species of grass called bird-grass. He obtained it from Virginia, where it grows, though it is not a native grass. The intention of putting it into my hands was, in order that I should cultivate it, and be thence able to form a judgment whether it might have any peculiar properties not found in our grasses, that would render it an advantageous article of culture here. He had, himself, conceived a very high opinion of it, by the information he had gained concerning it, from the country whence it came; and intended, as soon as he should have due proof from experiment, of what he hoped, to bring it before the Society for the Encouragement of Arts, &c. who had, with public-spirited zeal, entered very minutely into the consideration of the means of improving pastures. Being very solicitous to acquit myself of the trust, I carefully preserved this little treasure till the month of April, which I thought might be a fit time to sow it. Not being acquainted with the particular nature of this grass, I prepared the ground for it, in the same manner I should have done for a flower-bed: raking it with a wooden rake: I did this as I was willing by every means to secure its coming up: but such care would not have appeared in the least necessary, had I known its great hardiness, and force of vegetating power, as I have done since.

"At the time I expected the bird-grass to rise from my seed, I found the weeds and common grass coming up very thick: so that I could not distinguish the desired kind from these intruders: particularly the poa-grass. Being a stranger, as I before said, to the appearance of the bird-grass, I thought it the best way to weed out the other grass and herbs which I knew, and to let what I could not distinguish to be so, remain in the ground: and my eagerness was so great to perceive whether the bird-grass was come up, that I went almost every hour to look after it. I discovered it at last, in about a month from the time of its being sown, by its having a deeper green hue than is commonly seen in our grasses: and I transplanted it as soon as I imagined it would bear moving, into some of the same kind of ground, as that on which it had been raised: having first turned it up and cleared it from weeds. The size of this piece of ground was about twenty rods: part of it a little gravelly, and the other part of it moory land. I soon perceived the bird-grass grew better on the gravelly than on the moory part of the ground. That on the gravelly being of a better colour and sweeter than that on the moory; which was pale and yellow. And with respect to the moory ground itself, one part was moister than the other, and the bird-grass grew better on the drier side than on the wet. The grass, however, looked well all the summer, and in the month of September following, I began to gather the seed, and proceeded in it till October. The quantity of seed was above twelve pounds.

"The first year the grass did not grow to above two feet and a half high: but the second it rose to be four feet high. On the fourteenth of June of that year, being 1765, I measured out ten rods of this grass, and cut it. Three days after I weighed the product of this ten rod, herb and seed together: and they amounted to twelve hundred pounds. The tenth of August following, the same grass was again grown to the height of two feet eight inches, and was a second time fit to cut for hay: but I did not cut it; because I wanted a second crop of seed: which I obtained in the beginning of October; and it proved a much greater crop than the former. About this time a good deal of rain fell, which occasioned me no small share of trouble in drying the grass, and turning the little cocks. I then first remarked that shoots were made from almost every

every joint, in consequence of the moisture: but from some more than others: and of these many were of a finger's length. Had I not suffered this grass to stand, that I might have the seed, I am satisfied I could have mowed it thrice in the year; but wanting to collect as great a quantity as I could of the seed, I have not yet actually tried that experiment. I am very confident, however, that this kind of grass may be brought to afford eight tons of hay per acre in the year: and any person who may entertain doubts of the reasonableness of this supposition, may have them cleared up by ocular proof, if they will take the trouble to call on me; as great numbers of gentlemen have already done, to their entire satisfaction in this point. The latter end of May, and the beginning of June, will be a proper time for such inspection; as this grass, being a forward kind, will be fit to cut at that season.

"This grass has a peculiar quality, different from what is found in any other kind I ever knew before; which is that it had very short joints, and that every joint sends out shoots which strike root whenever they touch the ground. On taking a full grown plant of the grass out of the ground, it will be found; moreover capable of being divided into twenty smaller roots or off-sets, proper to be again planted: and these off-sets though taken thus from the root, even in the beginning of July, will bear seed the same year. If, likewise, when this grass is ready to be moved there should happen to be much rain, no damage will ensue in waiting a month for fair weather. Because, as this grass is constantly sending out shoots at every joint, it always keeps fresh; and does not wither, nor rot at the bottom as other grasses do: but, on the contrary, it continues green, even till the seed is ripe, which is certainly a very singular property, and of great consequence.

"The goodness of this kind of grass may also be very obviously inferred from the following particular. When I had sowed it, which was in the month of April, 1764, I had, as I have above declared, only one ounce and a half of seed: but betwixt that time and the present, I have found such a surprising increase, that I have collected from the successive crops of this ounce and a half, as much seed as has sown two hundred and fifty acres of land; and have besides, as much by me at present, as will sow one hundred acres more.

"I shall not dwell any longer on the commendation of this grass, than only to say, that it has every quality requisite to make good hay. That it is easily propagated, and from a very small portion of seed. That it is not subject to rot, or fall in patches, as most other kinds of grass do. That it is a beautiful green at all times, and consequently affords a most pleasing verdure, when sown in sight of any house, or made part of any prospect. And, lastly, that the produce of hay from it is extremely great, being much more than any other kind of true grass will yield. Of the truth of all this many persons can witness, who have, on seeing the real trials respecting it, given the greatest encomium on it: I shall therefore proceed now to offer some directions for its culture.

"The ground on which the seed of this kind of grass is intended to be sown, is to be prepared in the manner that is proper for lucern; that is it should be well ploughed and harrowed; and cleared, as much as possible, from all weeds, in the same way as is done for barley. When the ground is well mellowed and sweetened, the seed may be sown: the quantity of which may be about one pound and a half per acre; and the time of doing it, from March to April.

"Before the bird-grass seed be sown, it will be proper to sow as much barley or oats, as will afford half a crop, and such barley or oats being harrowed in, the pound and half of bird-grass seed should be sown over it: after which, in general cases, the ground is only to be rolled the first opportunity when it is dry. But if the soil be sandy or dry, it may be proper to give it a very light harrowing.

"This kind of grass cannot be well sown without some corn. Because it is of so fine and delicate a nature, at its first coming up, that the weeds would overpower and choke it at that time: or a greater expence would be necessary for clearing them away by hand. But when this grass is so mature as to be in the state of a pasture, or fit to cut, it grows so close and thick, that if a handful of money was thrown up over it, none would, when fallen, I am certain, reach the ground.

"As to the nature of the soil proper for the culture of bird-grass, almost every kind will do very well for it; except, as has been observed before, such as is too wet or

moory; and this is one of the good properties of this grass, because few kinds flourish much on dry gravelly ground.

"This is a just account of the observations and experiments I have hitherto made on this valuable grass; and they seem sufficient to justify me, in endeavouring to render it known to the public, as an object worthy their attention."

BIRD'S-NEST, the name of a weed, otherwise called wild carrot. See *Wild CARROT*.

BISHOPING, a cant term made use of by horse-jockies, implying the unfair practices they make use of to conceal the age of an old horse, or the ill properties of a bad one.

BIT, or **BITT**, the iron part of a bridle, put into a horse's mouth.

BLACK, a colour in horses, esteemed very beautiful, especially when they are of a jet shining black, and well marked, without having to much white: for as a great deal of white, especially when it spreads round their eyes, and a great way up their legs, adds nothing to their beauty, so neither does it add any thing to their goodness. The English black horses have more white about them than the black horses of any other country. The Spanish, Arabian, Dutch, and Danish horses, seldom have much; though a star or blaze, and sometimes a white muzzle, and one or more of the feet tipped with white, always looks beautiful and lively, and is so far from being a diminution of the goodness of a horse, that most think it an addition, from an opinion that horses without marks are generally stubborn and ill-conditioned. Some black horses have brown muzzles, are brownish on their flanks, and between their hips. These are often called black browns, as they are not a perfect black, but approach near to the colour of a tawny black hound; some are of a lighter colour about their muzzles, and are called mealy-mouthed horses; and of these sort are the pigeon-eyed horses, which have a white circle round their eye-lids and their fundaments often white. Those that partake most of the brown, are generally the strongest in constitution. *Gibson on Horses, vol. I. p. 46.*

BLACK CANKER, a species of caterpillar very destructive to turnips, and other plants, which Mr. Young, in the second volume of his *Annals of Agriculture*, gives an account how they were effectually destroyed by Mr. Coke at Holkam in Norfolk; who ordered his bailiff to buy all the ducks he could get, who presently collected 400; on the 16th of July they were turned into the thirty-three acres, having water at one corner of the field, and in five days they cleared the whole most completely, marching at last through the field on the hunt, eying the leaves on both sides with great care to devour every one they could see, and filling their crops several times in the day. The ducks having saved above sixty pounds worth of turnips, were sent to the poultry yards. The ducks might be allowed fifteen days for doing this work, in which case 400 ducks would secure 100 acres. Upon such a proportion, twenty or thirty might be employed on a small farm to great effect.

BLACK-GRASS, a species of grass in America, of which the following account is given by the late Dr. Elliot of New England.

"We have, says that worthy writer, in a letter to Mr. Mills, an excellent sort of grass in our salt-marshes. It thrives best and grows largest, in those meadows which border on tide-rivers, and have the greatest mixture of fresh-water. Where the water is very salt it is not apt to fix and spread; but will remain short and poor. It is very tender, and cuts as easily as garden cives, grows thicker and taller than the common salt-marsh grass, and affords from two to three tons of hay to the acre: but it is a slow grower, after it has been cut. Its seeds are small, like those of tobacco. The colour of this grass is a very deep green, which renders it so conspicuously different from every other kind, that it is universally known by the name of black-grass.

"This species introduced itself long since the settlement of New England. Our first planters knew nothing of it; nor has it yet travelled very far south-west. Its first appearance in this colony was on a marsh at Saybrook, to which an old boat was brought down Connecticut river, by a great flood and there cast up. This inclined me to think, that it was originally an inland grass which happened to suit with such salt marshes as are well supplied with fresh water; and what confirms me in this opinion is, that a person in the town of Killingworth, where I reside, having

cleared a swamp far distant from salt water, and afterwards sent into this fresh meadow, cattle which had been foddered with hay of the black grass, had there in a short time (undoubtedly by means of its seeds carried thither in the dung of these cattle) a fine growth of this very grass, which has since not only established itself, spread, extended, and, like a conqueror, beaten out the natural grass; but looks as flourishing in that fresh meadow, as any growing on a salt-marsh.

"I have a large tract of peat meadow, in which no grass feeds will grow. I design to try the seeds of this black grass in that dead fresh meadow, since the other sorts which I have tried do not succeed. What encourages me to do this, is my having introduced it into a once useless, worthless morass, worse indeed than nothing, though of considerable extent, for I was obliged to be at the expence of fencing it, for the sake of other land. It was quite over-run with reeds, bushes, and brakes.

"Between this land of mine and a creek of salt-water, intervened three meadow lots belonging to other persons. I obtained leave of the owners to cut a ditch six feet wide through their ground, and carried this ditch to the upper end of my land, where several cross ditches were then dug, to invite in, and retain the salt-water. The gaping mouths of these numerous ditches soon occasioned a strong indraught of salt-water, and, in time, converted the main ditch into a proper tide creek. The salt water thus introduced has done wonders. It has not only killed the trees, bushes, brakes, and levelled great inequalities, but has also introduced the black grass, and thereby rendered an acre of that land, which was not worth any thing before, now worth thirty-five pounds of our occurrency.

"The salt-water in its passage through my neighbours' ground has also done them great service, by introducing this black grass; and all this with small expence." *Mill's Husbandry, vol. III. p. 416.*

To this account of the black grass given by doctor Elliot, we shall add the following, transmitted in a letter from that gentleman's son-in-law, the reverend doctor Gale.

"Its (the black grass) early spring and growth, its lively green, its great produce, the preference given to it by cattle, when distributed promiscuously with salt grass for their food; its rendering the turf of mirey, loose, dirty meadows, firm and solid, and its extraordinary quality when improved for pasture in the spring and summer, raised its reputation, and endeavours were used to propagate it: but it proved very fullen and uncertain in its growth; growing only where it listeth, from the seed promiscuously shed, and wafted about by the tide which overflowed the meadows.

"It is observed to grow and flourish well near the banks of rivers, which admit the salt water, and even in flat or low meadows, which are in some measure overflowed every tide by the salt-water: but these low meadows must also be of that kind only, where there is a course of fresh water when the tide is out: so that a mixture of both fresh and salt water seems to be necessary for its prolific vegetation.

"It grows largest and best in reedy and rushy coves, or arms of the salt meadows, which are a little higher than the general level of the salt marsh, which are not commonly overflowed by the flux and reflux of the tides, which lie at some distance from salt creeks or courses of salt water, and which are watered by fresh springs rising from the banks or adjoining uplands.

"I have seen several such meadows which flourish remarkably with this sort of grass, though but lately brought under culture: am credibly informed, that eight acres of such a cove produced this year thirty-two tons of black grass in an adjoining township.

"The black grass is not near so much impregnated with salt as the common grass is, when both of them grow together; and the dew which adheres to the black grass is fresh, when that on the salt grass is highly pregnated with salt.

"It thrives best on a clay or strong loam. The natural turf should be broken, and the seed, after being mixed with fresh cow dung, should be spread, and fastened in by treading, that it may not be carried off by the water; or it may be propagated by transplanting the turf taken from a black grass meadow, by which means it will be made to spread apace.

"It will also grow where salt water never reaches. I have seen it growing on moist upland, and the turf has been so firm, that it was hard work for six oxen to plough through it."

We shall only add, that the above gentlemen has just sent the Society for the Encouragement of Arts, &c. a considerable quantity of the seed of this black grass; and that they have distributed it to a number of gentlemen, in order to their sowing it on proper soil; so that there is great reason to hope that this valuable grass will soon be as well known in England as it is in America.

BLACK-LAND, a name given to a particular sort of clayey soil, which is rather a grey than a true black. But however pale it may be when dry, it always blackens by means of rain: and when ploughed up at those seasons, it sticks to the plough-share and the more it is wrought the muddier and duskier coloured it appears.

These sorts of lands when somewhat fat, yet porous, light, and sufficiently tenacious, are good both for corn and grass; but as they are mostly in bottoms, so the wetness of them often spoils them for corn; but where they are dry, they are extraordinary fruitful, especially for barley; they will bear also good wheat upon an erish crop: but if they are so very rich, that your fear lodging of the corn, you may, if a deep mould, plant them with liquorice or sow them with hemp, woad, cole, rape seed, madder, or some other rich commodity, that best agrees with such land; and afterwards with corn, when some of the fertility is abated. The natural produce of these lands is commonly thistles, docks, and all sorts of rank weeds and grass. It will bear excellent clover. The best manure is chalk, lime, dung, &c. *Mortimer's Husbandry, vol. I. p. 75*

BLACK-LEGS, a name given in Leicestershire to a disease frequent among the calves and sheep. In Staffordshire they call it the wood-evil.

It is a white jelly, and sometimes a bloody jelly, settling in their legs, from whence it has its name of black-legs, and often in the neck between the skin and the flesh, which will make them carry their necks awry. If it falls on the joints they overcome it; but if on their bowels they die, nor is there any cure. *Lisle's Husbandry, vol. II. p. 135.*

BLACK OATS, a species of oats greatly cultivated in the northern parts of England, being esteemed a very hearty food for horses. See the article OATS.

BLACK THORN, a species of bushes well known, and much used in making fences, &c.

It is not reckoned quite so good for fences as the white-thorn, because it is apt to run more into the ground, and is not so certain of growing; but then the bushes are much the best, and most lasting of any for dead hedges, or to mend gaps: nor are cattle so apt to crop them as the other. They will grow on the same sort of soil with the white-thorn; but the richer the mould is, the more they will prosper. *Mortimer's Husbandry, vol. I. p. 5.*

BLADE, the spire of grass, or green shoots of corn.

BLACK TWITCH, the festuca duriuscula of Linnaeus, a noxious plant, which flourishes notwithstanding the extreme dryness of a season; and is very injurious to any crop.

BLAIN, a disease to which cattle are subject in the spring of the year. Some think it is occasioned by a little red worm which the cattle lick up. It often occasions a bladder as large as a hen's egg under the tongue, and when this happens, the beast may be cured by breaking the bladder, and rubbing it with salt.

Others impute the disease to a sudden rising of the blood; and may be known by the beast's eyes running with water; and as the distemper advances, its eyes will swell, and, if bled under the rump, the blood will feel hot. In this case the following drench is recommended. Take a pennyworth of English liquorice, and an equal quantity of English aniseeds, turmeric, long-pepper, horse-spice, or diapente, all ground fine, and just boiled up in a quart of strong beer; but if the heat of the blood indicates that the distemper proceeds from a hot cause, the horse-spice should be omitted. It is added, that if the bladder cannot be found under the tongue, the bum-gut should be raked, where it will be found in the back. If a knife be run through the ear of a beast near the root, it will, according to the report of experienced graziers, prove a certain cure in this distemper, provided it be done before the beast falls. *Lisle's Husbandry, vol. II. p. 127.*

BLAST, the same with blight. See BLIGHT.

BLAZE, a white mark in a horse's face.

BLAZES. It is a notion, that those horses that have white faces or blazes, if the blazes be divided in the middle, crossways, is the mark of an odd disposition.

BLEA, that part of a tree which lies immediately under the

the bark, or between that and the hard wood, and is the first progress of the alteration of the bark into wood, by the natural growth, and strengthening the fibres.

While the blea remains any thing soft, and retains somewhat of the nature of bark, it may maintain a feeble vegetation; but when it is grown absolutely hard and woody, it can no longer contribute to carry on that operation.

BLEEDING, an operation frequently necessary among all kinds of cattle particularly horses; and consists in opening a vein by means of an instrument called a fleam.

Those horses that stand much in the stable, and are full fed, require bleeding more than those which are in constant exercise; but especially when their eyes look heavy and dull, red and inflamed; or when they look yellow or inflamed in their lips, and insides of their mouths; when they seem hotter than usual, and mangle their hay. These are all indications that require bleeding, and likewise to lower their diet till they have more exercise.

Young horses should be bled when they are shedding their teeth, which is a relief to them, and removes those feverish heats, to which they are subject at that time.

The spring is always a proper season for bleeding, because their blood is then more luxuriant than at other times; and in summer it is often necessary to prevent fevers, always choosing the cool of the morning, and keeping them cool the remaining part of the day.

Some bleed their horses three or four times a year, or even oftener, by way of prevention. These take a very small quantity at a time, not exceeding a pint, or a pint and half, only to give a kind of brisker motion to the blood, and by that means to preserve or render it more thin and fluid, and to prevent its stagnating in the smaller vessels, which indeed is the first beginning of almost all diseases; but how far this succeeds, can only be known to those who have practised it a sufficient time. There is, however, this inconvenience from frequent bleeding, that it grows into a habit, which in some cases, cannot be easily broken off without hazard; and some horses have been known to become weak from frequent bleeding, while others have had their necks so full of scars, that they are apt to inflame and fester every time they are bled, which is always troublesome, and often ends with the loss of the vein. And therefore to prevent such accidents, those who bleed horses should not confine their operation to one place of the vein, as they generally do, but use themselves to open it higher or lower as they see occasion; and if they meet with any difficulty in bleeding in the neck veins, the plate veins, or any other large veins, that can be made to run a full stream, will equally answer the same end.

But the cases that require bleeding most, are colds, fevers of almost all kinds, falls and bruises, which are sometimes dangerous to horses, because of their great weight. Hurts and wounds of the eyes, strains in hard riding, or drawing, and all other accidents where a stagnation of the blood may be suddenly expected, or where the small vessels may be broke, and the blood extravasated. Those horses that refuse their food after riding, or any sort of work, require to be bled more frequently than others, to prevent fevers, and inward inflammations of the lungs, the liver, or any of the principal viscera. Nor is it less necessary to bleed horses at grass, when the purgation is over, and they begin to gather flesh, or at any other time, when they look heavy about their eyes, for this is a proper indication for bleeding; and some rank pastures require more bleeding than others.

There are also other indications that require bleeding by way of prevention, viz. when any epidemic distemper prevails among the horses; at such times the sound ones may be bled, to keep them, if possible, from being infected; and if the contagion continues, it may not be amiss to repeat the bleeding once in two or three months, or oftener, but in small quantities, for the loss of too much blood may be hurtful in some times of contagion. It is likewise necessary to keep sound horses from the unsound, or to remove them into places where the infection has never spread itself. *Gibson on the Diseases of Horses*, vol. I. p. 218.

BLEYME, an inflammation in an horse's foot, occasioned by blood putrefied in the inner part of the coffin towards the heel, between the sole and the coffin-bone.

There are three sorts of bleymes; the first, bred in spoiled, wrinkled feet with narrow heels, are usually seated in the inward or weakest quarter; the second, besides the usual symptoms of the first, infects the gristle, and must be extirpated, as in the cure of a quitter-bone.

See **QUITTER-BONE**. The third is occasioned by small stones, or gravel, between the shoe and the sole. For the cure they pare the foot, let out the matter, if any, and dress the sore like the prick of a nail.

BLIGHT, a general name for various distempers incident to corn and fruit trees.

It is well known that this disease is most injurious in a wet season; and hence, principally, the scarcity and advanced price of wheat after such seasons. It is also remarked to affect the north side of a field much more than the south, and that the effect is governed by the state of ripeness; and that a few days of forwardness may be sufficient to prevent the effect. For the south sides of ridges, though always forwarder, are seldom ripe more than a few days before the north side. It is evident from observation, that the forward wheats, are least liable to be blighted; for that having passed some certain stage of maturation, they become invulnerable to the attack of this mischievous enemy; at least, no obvious injury is incurred. It is also observable that no perceptible blight takes place while a dry season continues. The only guard a farmer has against the attack of this secret enemy appears to be that of sowing early. *Marshall's Rural Economy of Midland Counties*.

M. du Hamel treats that part of this subject which relates to corn in a very masterly and instructive manner; dividing what we generally call blights into the following species, viz. empty ears, parched and shrivelled corn, glazed corn, abortive or rickety corn, barren corn, and fallen or lodged corn. The reader will find each under its proper articles, as **EMPTY EARS**, &c.

BLIND, deprived of the sense of sight.

Moon **BLIND**, or *lunatic*, a disease to which horses are subject, the symptoms of which are no other than the forerunners of cataracts, and generally end in blindness.

Signior Ruini, says that experienced writer Mr. Gibson, and most other foreign writers, both French and Italian, in treating the diseases of horses, have all of them reckoned the moon-blind symptoms as a peculiar disease of the eyes, without having any relation to a cataract, which they have considered apart, as another disease of the eyes, which shews they built more on looks than experience. But from many years observation, I do not remember I have even seen a cataract bred in the eyes of any other horses than those which were called lunatic, or moon-blind. The Arabians were the first that ascribed so much to the moon in the diseases of the human body: and after the decay of learning all over Europe, their superstitious notions were so firmly rivetted, and so universally prevailed, that they could not be easily exploded, even by the ablest physicians, till the modern discoveries in natural knowledge made way for more solid improvements in the medical art; and therefore it is no wonder, that the first writers on the subject of farriery, notwithstanding some of them were men of learning, should fall in with all the common superstitions that had so long prevailed, and had so great an influence on the practice of physic.

These writers have described this distemper as appearing at certain times of the moon, coming sometimes at the new-moon; sometimes at the full; and sometimes in the wane of the moon; that it sometimes returns once in three months; sometimes once in two months, and in some not above once in six months: that the eyes look so clear when the distemper abates, that it is impossible to see any imperfection in them. But these observations are very liable to exception; for any one who has the least knowledge of the eyes, must needs see, that when the distemper is the most abated, and the eye the most clear, it still shews a remarkable weakness, and upon full trial, the sight will be found defective. Neither could I perceive that the eyes were affected by any of the moon's periods, so as not to vary, unless by mere accident. And therefore these observations are neither of any great use to the knowledge of the distemper, nor to lead us into a right method of curing it when it happens.

I have already taken notice, that the symptoms which appear in the moon-blind horses, are, for the most part, no other than the prognostics of breeding cataracts. These symptoms generally make their first appearance, when a horse is turned five, coming six, at which time one eye becomes clouded, the eye-lids swollen, and very often shut up; and, for the most part, a thin viscid water runs from the diseased eye, down the cheek, which is generally more or less in proportion, as the eye and eye-lids happen to be more or less swelled and inflamed; and, in some constitutions

tutions, the inflammation is so great, and the humour so sharp and corrosive, that it scalds and fetches off the hair wherever it comes. The veins of the temples and under the eye, along the side of the nose, are also turgid and full: others run but little; nor is the humour very sharp.

This disorder is apt to come and go, till the cataracts are perfect and ripe, and then all pain and anguish, and the soreness and running of the eyes, go off with blindness, when the horse is between seven and eight years old, this being about the time when most horses are spread and come to their full growth; so that from its first appearance to its completion, is generally about two years, or two years and a half, during which time, some horses have the returns of the disorder, not only more frequently than others, but the symptoms also are more strong and violent. In some the eye is not much disturbed above a week, when it clears up again, and returns to its former state. In some horses the eye continues bad a fortnight or three weeks. In others a month or longer, before the disorder goes off; and the time of the return, so far as I could observe in many horses, was always uncertain, and could not be fixed to any period of the moon, as many have imagined, being sometimes sooner, sometimes later, according to its predominancy, or according to the treatment a horse meets with from his farrier and keeping. Some have their returns once within the space of two or three months; some within the space of four; and, with the greatest care and pains, the disorder seldom keeps off above five months, without a relapse.

This is usually the case of those moon-blind horses, which have their eyes strongly infected with a hot sharp humour, that shuts them up with swelling and inflammation. But there is another kind of moon-blindness which is also the forerunner of cataracts, where no humour of weeping attends the eye. It is never shut up or closed, as in the case above described, but will now and then look thick and troubled, at which time the horse sees little, and perhaps nothing distinctly. Here the eyes always appear sunk and perishing, though the cataracts do not become so soon complete, as in those that are full, and where a humour is predominant; nor is it unusual in this case for one eye to escape, whereby a horse will retain sight to guide him, so as to render him fit for common drudgery.

The causes of this distemper are various, and when it proceeds from a natural defect in the eyes, it may no doubt be hereditary; but in a horse that has naturally good eyes, and yet turns moon-blind, it is usually owing to lickness, or some other malady that has terminated in the eyes; though we seldom see horses turn moon-blind and breed cataracts, but where the eyes are naturally in fault. These eyes are, for the most part, faulty, that are very large and prominent, or very flat, small, and sunk; both which defects in the eyes of horses are liable to blindness, though they differ in their manner; and therefore colts, that have large eyes, that run abroad, always feed with their heads downwards, and are continually exposed to the sun in hot weather, may easily contract an habitual weakness in their eyes, especially as the blood and juices of all young animals are naturally of a viscid and balsamic texture, and thence may be the more easily retarded in the vessels of the eye, which are exquisitely fine. These causes produce weakness and relaxation in the eyes, and this still increases till the blood is in that state, which we may reasonably suppose to continue till a horse is done spreading, and turned seven, for then the cataracts generally grow complete. On the other hand, when the eyes are flat, and lie deep within their orbits, the surface of the eye being also flattish, the rays of light falling directly upon the pupil, and these not being sufficiently refracted, as they are in those eyes that are more convex, or of a rounder make, must needs weaken the eye, affect the optic nerve, and consequently weaken the tone of the muscles. And, perhaps, this may be the reason why the eyes perish and decay, while the cataracts are growing.

The signs of this distemper may, in some measure, be deduced from what has been already observed; viz. swelling and inflammation of the eyes alternately, sometimes one eye, and sometimes the other, with a running of a thin watery serum, which is often so hot and scalding, as to fret off the hair. In others the eyes run but little, and some not at all; but look deadish, sunk, and perishing. In all moon-blind horses, the eyes are sometimes tolerably clear, at other times thick and muddy, of a wheyish colour, or a dusky yellow; and when this happens, a

moon-blind horse sees but little, and when he is brought out into the light, he takes little notice of any person or object that is near him, but always looks upwards, with his head raised, lifts his feet high, and sets them down with fear. Though in this distemper the humour shifts from one eye to the other by turns, and at some intervals seems to go off, yet when the eyes of such horses are at their best, they look weak, and with a deadness, and when any such horse has his head held up, the weakness of the muscles, and of the whole eye, is easily perceived.

When this distemper happens to horses that have large full eyes, resembling those of a calf, and when the humour continues by long periods, and the returns are frequent, there is great danger of blindness. If the eyes be of a moderate size, well formed, and the periods or returns of the distemper short; if the horse sees perfectly when the humour goes off, and the eyes in those intervals look clear, the horse may recover. When the humour attacks one eye without changing to the other, there is also hopes of a cure, at least, of saving one eye. But when the eyes look flat and depressed, and decay gradually, it is generally the forerunner of blindness; for in this case the nerves and muscles of the eyes are affected, and the cataracts always grow in the progress of the distemper. Here, however, as in the preceding case, when the distemper seizes only one eye, the other may be sometimes saved, and when this happens, the remaining eye generally grows stronger when its fellow is gone. But when the distemper proceeds from a violent cold, as sometimes happens, whereby we often see the eyes swollen, and quite shut up, though the horse may be threatened with blindness by several returns, yet by good management it may sometimes be prevented, and the eyes recover. Nor does the distemper always prove incurable, when the eyes are darkened with a yellow cloud, provided the eye be not naturally bad, and the above symptom of long continuance. In all cases of moon-blindness, the most promising signs of a recovery are when the attacks come more seldom, and their continuance grows shorter: or when the inflammation and swelling in those eyes that are naturally full and large abates. Also, when the eyes, that looked sunk and perished, grow more plump and full; and when in either the cornea looks clear and transparent, without muddiness, and the horse looks more attentive to his way, and goes on without much fear or startling; all these are promising signs, and with good and careful management he may recover.

The most difficult part still remains to be treated of, namely, the method of curing this disorder, for few moon-blind horses escape; and when it is hereditary, or the eyes naturally defective, it is not advisable for any one to be at much expence and trouble to save them, as there is great reason to fear he will meet with a disappointment. We, however, sometimes see moon-blind horses, at least such as have many of the same symptoms, recover and do well, even beyond expectation.

If the eyes are large, full, swollen, and inflamed, the horse should be bled at proper intervals, sometimes in the neck, and sometimes backward, to make a revulsion. But where the eyes appear sunk or perishing, bleeding is often pernicious. After bleeding, for those that are full and run a thin sharp water, make a strong tincture of roses in the following manner.

Take two drams of red-rose-buds, either fresh or dried, infuse them in half a pint of boiling water in the manner of making tea; when it has stood to be cold, pour off the infusion, which will be of a reddish colour.

In four ounces of this tincture dissolve half a dram of sugar of lead, and wash the horse's eyes, and all over his eye-lids, with a piece of sponge, or a clean bit of rag, twice a day. If the matter digest and thicken, which usually happens before it abates, add to the whole quantity of this tincture about two drams of honey (which will dissolve in the fluid, by holding the phial near the fire, and shaking it) and use it as before. At the same time, if the parts near the eye be hot, and the veins over the face, and along the side of the nose be turgid and full, bathe those parts frequently with the best vinegar, verjuice, or vinegar of roses, till the heat and running of the eye abates, the veins sink, and become less apparent, and the eye begins to look clear. In the mean

mean time some lenient mild purges may be administered, such as the following :

Take lenitive electary and cream of tartar, of each four ounces ; syrup of the juice of buckthorn berries, two ounces ; mix these with white wine and water, warmed, about a pint, and give it fasting.

Or,

Take lenitive electary and cream of tartar, of each four ounces ; Glauber's purging salts, three ounces ; the solutive syrup of roses, two ounces ; to be mixed with white wine and water, or warm water-gruel.

Either of these may be given to moon-blind horses. The latter is rather the more mild and cooling, and exceeding proper if the horse be fat and full of blood, and will work so gently, that it may be repeated twice a week, till the eye becomes clear, and attains its usual brightness.

The horse should have feeds of scalded bran while these lenitives are given him, and he may have moderate exercise, or may be made use of in any kind of easy business ; for these draughts, for the most part, work off in about two hours. But as the blood, in all these cases, is generally fizy, and as this disposes young horses to frequent returns of the distemper, it is therefore necessary to administer such things as may attenuate the juices, and preserve them in a more fluid state. These are called alteratives, because their property is gradually to alter the state of the blood. The following has been often used, in this and many other cases, with great success :

Take the finest succotrine aloes, half an ounce, or six drams ; cream of tartar half an ounce ; fresh jallap in fine powder, and salt of tartar, of each one dram ; make the whole into a ball, with a sufficient quantity of oil of amber, and roll it in liquorice powder.

One of these balls may be given every week, in the manner of a common purge, with scalded bran, and his water milk-warm. The first day it will work plentifully by urine, and the day following both ways ; but no more than just to empty his guts, unless when there is a foulness, by reason of a redundant slime or grease ; when it will often work very powerfully two or three days, without the least diminution of the horse's strength, or loss of flesh. The alterative purges should be continued for a month or six weeks, and after omitting another month to begin again ; in all which time the horse may be kept in any common business, except hunting, going journies, or any other laborious exercise.

In the intervals between the purges it will be proper to give him an ounce of crude antimony every day, made into a fine impalpable powder, in one of his feeds, which may be continued for three months or longer. But if the horse be of value, instead of crude antimony, he may have powders compounded of native cinnabar, or cinnabar of antimony, and gum guaiacum, equal parts, giving him an ounce every day, till he has taken two or three pounds ; and after an interval of about three months, to proceed in the same method till the eyes look strong and clear, and the horse shews no signs of blindness, or any defect in his sight or weakness in his eyes. Several gentlemen have followed this method with good success, where the eyes have been full, and no way perished. A pound of guaiacum wood boiled in three gallons of water till it is reduced to two, is a cheap remedy, and may be profitably administered to horses of small value. It promotes perspiration, dries up superfluous humidity, strengthens the solids when relaxed, and sweetens the blood. It may be given a quart or two every day, in a horse's water, and will have a good effect to prevent moon-blindness, where it is not hereditary, nor proceeds from a natural defect in the eye.

But when the eyes are sunk and perishing, and the eye-brows are pinched at their inner corners next the nose ; when there is little or no inflammation or running, except a more than ordinary moisture in the caruncle, or haw of the eye, or where there is no moist-

ture at all, as we often find ; many moon-blind horses in wherever these symptoms are, a method of cure is required quite different from the preceding. For as we suppose here the nerves of the eye to be affected, and the supplies of the arterial blood by that means denied ; therefore, wherever the fault may be, whether originally in the blood or in the nerves, it is necessary, in either case, to administer such things as not only attenuate the blood, but may cause a greater derivation thereof to the eye : so that the most likely way to succeed is by the proper use of mercurials ; and these such as are the most efficacious, and at the same time the most safe. But first of all let the horse have the last mentioned purge given him by way of preparation, and when the operation is over, which will be mild and gentle, the following ball may succeed :

Take mercurius dulcis that has been often sublimed and dulcified, two drams ; make it into a small ball, with a sufficient quantity of conserve of red roses, and wheat flour.

Let this ball be given early in the morning fasting, and tie up the horse from eating two or three hours after it ; then let him have a feed of scalded bran, with warm water, or warm gruel to drink ; which regimen ought to be continued the whole time he is under this course of mercurial and purging physic ; cold water and other cold drinkables being somewhat unsafe at such a time. The mercurial ball may be repeated every other day, in the morning, till the horse has taken three or four. If his mouth grows tender, which may possibly happen, if he be not of a pretty strong constitution, he must be fed with water-gruel for two or three days, till that symptom wears off. At the same time the purge may be repeated once or twice, and the following eye-water applied outwardly to both his eyes, if both be weak and disordered :

Take crude sal ammoniac, cleaned from the black scurf that is usual on the outsidess of the cakes, two drams ; dissolve it in a pint of warm water, or the above tincture of roses ; and add to it a gill of spirit of wine, or the best brandy, shaking them together in a quart bottle.

The eyes may be bathed all over with this mixture, twice a day, or it may be used in the manner of a fomentation, by wringing cloths out of it, and applying them warm over the eyes. This will act as a stimulus, and may also help to thin and rarefy the gummy juices, and bring new supplies of nourishment to the perishing eyes. At first it may cause a little smarting ; but after using it a day or two that symptom goes off, and if the eyes grow more plump and full, there will be hopes of a recovery, at least of saving one eye ; and therefore the best way upon this prospect is to proceed in the same method, after a month's interval, and so on, as you find encouragement. And in all the intervals, the powders mentioned above should be given in all his feeds, or the decoction of guaiacum in his water.

Some take up the eye veins to prevent blindness, but without distinction, whether the eyes are full with redundant humours, or sunk and perishing. In the latter case the taking up the veins may possibly be of service, because by that means the eyes may be better supplied with its proper nutritive juices ; but this too is uncertain, because the fault may be in the nerves, or the distemper may proceed from some original configuration of the eye, which may be defective, and then such operations are like to prove fruitless. But the taking up the veins where the eyes are full, must, for the most part, prove hurtful, by cutting the channels which should convey the blood and juices from thence in the course of circulation, and consequently increase the distemper, instead of abating it. In this case the taking up the arteries might be of some service ; but this is an operation that only persons well skilled in the anatomy of a horse, should presume to undertake, and in the end might perhaps be uncertain.

The cutting out the haw is another operation usually performed on moon-blind horses. The haw is a swelling or sponginess of the caruncle or fleshy substance in the inner corner of the eye next the nose, and when it is soaked with

too much moisture and humidity it swells and turns spongy. The membrane to which it adheres also grows thick, and spreads itself so as to cover a considerable part of the eye, but seldom reaches so far as to cover any part of the pupil. The ligament which runs along the verge of this membrane becomes horny; and when it rises to this state, it compresses the eye-ball like a hoop, and by its continual pressure causes constant pain, and increases all those bad symptoms that are the fore-runners of blindness. Haws grow sometimes in eyes that are not naturally bad, after colds and surfeits; but moon-blind horses are seldom without them; and wherever this symptom appears, that the haws grow large and spongy, and derive a drain of humours upon the eye, the operation becomes necessary, and is performed by taking hold of the membrane with a small hook, and cutting off so much of the caruncle as looks moist and spongy, with part of the membrane and gristle that cause a pressure on the eye. When this operation is well performed, it does great service, and often recovers horses that are not subject to cataracts; and even in this case it makes the eyes look something better, and helps to protract the blindness, but will not prevent it when it is hereditary. This is an easy operation, and what almost every farrier pretends to; but they are apt to cut off too much of this substance, and by that means weaken the eye, and forward the blindness, instead of preventing it. The proper application after cutting out the haw, is honey of roses, or rather tincture of roses, with a little honey dissolved in it. But if the eye continues still to abound with moisture, after the haw is extirpated, and threatens a fresh fungus, the case may be deemed bad; and then it will be necessary to blow into it a small quantity of burnt alum and fine loaf-sugar; and in some cases it may be touched with the blue vitriol-stone, or the lunar caustic; but these violent symptoms seldom happen, and when they do, we may suppose the blood to have a very bad disposition: so that it will be hardly worth while to attempt a cure, considering both the length of time, and the uncertainty of success. *Gibson on the Diseases of Horses*, vol. I. p. 326.

BLINDNESS in Horses, may be thus discerned: the walk, or step of a blind horse, is always uncertain and unequal: so that he dares not set down his feet boldly, when led in one's hand: but if the same horse be mounted by an expert horseman, and the horse himself be a horse of mettle, then the fear of the spurs will make him go resolutely and freely, so that his blindness can hardly be perceived.

Another mark by which you may know a horse that has lost his sight, is, that when he hears any body enter the stable, he will prick up his ears, and move them backwards and forwards; the reason is, that a vigorous horse having lost his sight, mistrusts every thing, and is continually in alarm at the least noise he hears.

BLINDNESS, a want of sight. The sheep in some parts of Wiltshire are troubled with a blindness, and are cured by anointing their eyes with goose-dung. *Lisle's Husbandry*, vol. II. p. 212.

BLISTERING ointment, a name given by farriers for a sort of charge or plaster for raising a blister in horses. There are various prescriptions for making this ointment, but the following is equal to any yet known:

Take nerve and marshmallow ointment, of each two ounces; quicksilver one ounce, thoroughly broke with an ounce of Venice turpentine; Spanish-flies powdered, a dram and a half; sublimate, one dram; oil of origanum, two drams.

BLOOD, a red liquor circulating through the veins, arteries, and other vessels of animal bodies; and serving for the support of life, and nourishment of all their parts.

Blood is an excellent manure for almost any sort of soil. Mr. Evelyn tells us, that after the battle of Bagnam-fields, in Devonshire (where lord Hopton obtained a signal victory) the blood of the slain fertilized the land, which had been sown with corn a little while before, to such a degree, that most of the wheat-stalks of the ensuing crop bore two, three, four, nay seven, and some even fourteen ears; a thing almost incredible. The owner of the land seeing how miserably it had been trodden down, thought of re-sowing it; but was dissuaded from that design (perhaps to make the experiment) and had the above-mentioned surprising crop. The husbandman should, therefore, be careful to procure the offals of the shambles, where they are to be had, as they will prove an excellent manure.

BLOOD, a distemper in the backs of cattle, which will make a beast go as if he drew his head aside, or after him. In order to cure it, you should slit the length of two points under his tail, and let him bleed well; but if he bleeds too much, bind his tail next the body, and then bind salt and nettles bruised into it.

BLOOD, *ebullition of the*. A disease in horses which proceeds from want of exercise, and gives rise to outward swellings, frequently mistaken for the farcin.

BLOOD-*running Itch*, happens to a horse by the inflammation of the blood, being overheated by hard riding or other hard labour, yet gets between the skin and the flesh, and makes a horse to rub, scrub, and bite himself; which if let alone too long will turn to a mange; besides the general ones of bleeding in the neck-vein, scraping him, and other things, are various.

BLOOD-*shoten eyes in horses*. In all inflammations of the eyes, whether from external or internal causes, bleed immediately, according to the strength of the horse; purge once every week, and on the days that purges are not operating, let diuretics be given, such as nitre, to two or three ounces a-day, in mashes of bran. The diet, if in the house, should be mashes of bran, or scalded barley; and, while the inflammation is considerable, hay, oats, and all hard meat which requires chewing, should be avoided; hard labour, and sometimes hanging down the head to graze, is hurtful.

Dip a doffel of lint, or a very soft sponge, in the following eye-water, and wash the eye-lid with it two or three times a-day; and, if opportunity favours, squeeze the sponge so as a few drops may run into the eye each time you bathe it:

Take of red-rose leaves dried, two drachms; infuse them in half a pint of boiling water, until it is cold; then add to the strained liquor, twenty grains of sugar of lead.

When the inflammation is nearly gone, the following will be the most proper for completing the cure; as it not only repels the humours, but greatly strengthens the vessels also.

Take of white vitriol, half an ounce; sugar of lead, one drachm; dissolve them in a pint of pure water.

If the inflammation is very considerable, and the veins on the inside the eye-lid are very full, much relief is given by opening one of the most turgid of them with a lancet.

If there is much swelling, as frequently happens after blows, bites, &c. a poultice of scalded bran, or the crum of white bread boiled, must be applied, and renewed as often as it cools.

Sometimes, from the violence of the inflammation, the coats of the eye lose their natural transparency, and turn white, or of a pearl colour: in consequence of this, the sight is greatly diminished, if not totally obstructed: but sometimes a white blister forms itself on the cornea, as large as a grape: this always relieves, and when it breaks, the cure is speedily effected.

In gross habits, and where there seems to be naturally a weakness in the eyes, disposing to this disease, recourse is sometimes had to rowelling, with considerable advantage.

It may not be amiss to give in this place a caution against the use of powders in eye-waters; for, in the state of inflammation, the eye is very tender, and the finest powder will irritate it, and occasion more or less pain; therefore, medicines that admit of solution, are the only proper ones in these cases.

BLOOD-*letting*. See the article BLEEDING.

BLOOD-*spavin*, a swelling and dilatation of the vein that runs along the inside of the hock, forming a little soft swelling in the hollow part, and is often attended with a weakness and lameness of the hock.

The cure should be first attempted by bathing the part twice a day with vinegar or verjuice; or fomented with a decoction of oak-bark, pomegranate, and alum, boiled in verjuice, binding over it, with a roller, a woollen cloth soaked in the same, which will contribute greatly to strengthen all weaknesses of the joints, and, if early applied, will frequently remove the disorder: but if by these means the vein is not reduced to its usual dimensions, the skin should be opened, and the vein tied with a crooked needle and waxed thread passed underneath it, both above and below the swelling, and the turgid part suffered to digest away with the ligatures: for this purpose the wound may be daily dressed with turpentine, honey, and spirit of wine, incorporated together. *Bartlett's Farriery*, p. 279.

BLOSSOM, a general name for the flower of plants, but more especially of fruit-trees. See **ORCHARDS**.

BLOSSOM, or *peach-coloured horse*, is one that has white hairs intermixed all over with sorrel and bay hairs.

Such horses are so insensible and hard, both in the mouth and in the flanks, that they are scarce valued: besides that, they are apt to turn blind.

BLOW-MILK, skimmed, or *floten-milk*: that from whence the cream is blown off.

BLOWN, swelled or hove. See the article **HOVED**.

BLUE-BALL, a name given to the cone-wheat in Somersetshire, from the dark colour on the edge of the husks of the chaff, which cover each grain, and the falling off of the awns when ripe; some of the ears having awns, and others none. See the article **CONE-WHEAT**.

BLUE-BOTTLE, *knappweed*, *matfellow*, or *centaury*, the name of a weed abounding in many corn lands, flowering in July, and ripening its seeds in autumn.

Mr. Miller says the corn blue-bottle is an annual plant; but Mr. Ray and Mr. Lisle think its root is perennial; because, as the latter observes, it not only puts forth new buds every summer at the root for the growth of the next year, but seems also not to seed early enough, before the corn is cut, to propagate itself by its seed in corn-lands, in which it most abounds, especially in a gravelly soil.

BLYPE, the same with *bleyme*. See **BLEYME**.

BOAR, the male swine. See the article **HOG**.

BODY of a horse, the material part or substance of a horse, usually called his carcase. See the article **CARCASE**.

BOG, properly signifies a quagmire, covered indeed with grass, but not solid enough to support the body; in which sense it differs from moors or fens only as a part from the whole. See the articles **MOOR** and **FEN**.

Mr. King, in his account of the bogs in Ireland, published in the *Philosophical Transactions*, Numb. 170, imputes the true cause of them to want of industry.

"The springs, says he, with which Ireland abounds, are generally dry, or near dry in the summer time, and grass and weeds grow thick about the places where they burst out. In the winter, they swell, run, and soften, and loosen all the earth about them. The sward or scurf of the earth, which consists of the roots of grass, being lifted up and made fuzzy by the water in the winter, as I have seen it lifted up a foot or two at the head of some springs, is dried in the spring, and does not fall together, but withers in a tuft, through which arises new grass; which is also lifted up the next winter. By this means the spring is more and more stopt, and the scurf grows thicker and thicker, till at first it makes that which we call a quaking-bog; and as it grows higher and drier, and the roots of the grass and other vegetables become more putrid, together with the mud and slime of the water, it acquires a blackness, and grows into that which we call a turf-bog. I believe that when the vegetables rot, the saline particles are generally washed away with the water, as being apt to be diluted in it. The oily or sulphureous, are those which chiefly remain, and swim on the water; and this is that which gives turf its inflammability.

"I must confess, that there are quaking-bogs caused otherwise. When a stream or spring runs through a flat, the passage, if not tended, fills with weeds in summer, trees fall across it, and dam it up: then, in winter, the water stagnates farther every year, till the whole flat is covered. Afterwards, a coarser kind of grass shoots up, peculiar to these bogs. This grass grows in tufts, its roots consolidate together, and its height increases every year; inso-much that I have seen it as tall as a man.

"This grass rots in winter, and falls on the tufts, and with it the seed, which springs up the next year, and so still makes an addition. Sometimes the tops of flags and grass are interwoven on the surface of the water, and this becomes by degrees thicker, till it lies like a cover on the water: then herbs take root in it, and by the matting of their roots it becomes very strong, so as to bear a man. I have gone on bogs which would rise before and behind, and sink where I stood, to a considerable depth; under which was clear water.

"As a farther proof that want of industry is the principal cause of bogs, Mr. King observes, that the highest mountains in Ireland being full of springs, and uninhabited, are over-run with bogs, as well as the plains, because no care is taken to clear the springs.

"Ireland, continues he, abounds in moss more than, I believe, any other kingdom. This moss is of divers kinds, and that which grows in bogs is remarkable. The light spongy turf is nothing but a congeries of the threads of this moss, as I have already observed, before it be sufficiently rotten. The turf then looks white, and is light. I have seen it in such quantities, and so tough, that the turf-spades could not cut it. In the north of Ireland, they call it *old-wives tow*, being not much unlike flax. The turf-holes, in time, grow up with it again; and all the little gutters in bogs are generally filled with it. To this I chiefly impute the red or turf-bog; and from the same cause even the hardened turf, when broken, is stringy; though there plainly appear in it parts of other vegetables: and I am almost, from some observations, tempted to believe, that the seed of this bog-moss begets heath, when it falls on dry and parched ground. However, the moss is so fuzzy and quick-growing a vegetable, that it greatly stops the spring, and contributes to thicken the scurf, especially in red bogs, where I remember to have observed this most particularly."

A flat spot of ground lower than the level of an adjoining river or lake, may also give rise to a bog; for when that part is filled up by the slime and earth brought from the surrounding grounds, and the rotten plants and animals, which are buried in it, have choaked it up, it will become a bog; and then the water will continue to flow into it from the river or lake, especially when either of these is swelled by a fall of rain, or melting of snow. These waters may also sometimes have this effect, without a communication above ground, by soaking through a sandy or gravelly soil.

Another cause of bogs have frequently arisen from the fall of a number of trees, which, being neglected, have necessarily occasioned a stagnation of the water brought down from higher grounds; so that the earth and other soil conveyed with it, have of course remained among the fallen wood, and given birth to a mossy ground, which, it is plain from hence, is not an original soil. Coarse grass, and weeds which cattle will not eat, spring up in these places, and die there, after shedding their seeds, which, being prevented from rotting by the bituminous acid in the mossy water, produce new plants; so that, this being repeated every year, an annual addition is made to the depth of the moss.

Bogs, draining of. Among the many and great inconveniences which necessarily arise from bogs, Mr. King mentions the following, as cogent reasons why every endeavour should be used to bring them, first to a less hurtful state, and afterwards to a condition in which they may be of service to mankind.

"The finest and smoothest plains, which generally should be meadows, are often covered with useless, too often with really pernicious bogs. These bogs are a great destruction to cattle, the chief commodity of Ireland. In the spring time, when the cattle are weak and hungry, the edges of the bogs are commonly clothed with grass, and the beasts, in venturing to get it, fall into pits or sloughs, where they are either drowned, or, if they are found, hurt, and often maimed, in the pulling out. The fogs and vapours which arise from these places are commonly putrid, and very unwholesome: for the rain which falls on them, stagnating upon their surface, and in their hollows, than which there is hardly any substance, equally soft, more impenetrable by water, corrupts there, and is exhaled by the sun; so that, very little of it running off, it must of necessity affect the air. They corrupt other water, both in its colour and taste: for the water which stands in the pits, or lies on the surface of the bog, is tinged by the reddish-black colour of the turf; and when a shower comes, so as to make these pits overflow, the water which runs from them tinges all it meets, and gives its colour and stench even to many rivers. The only advantage derived from any bog, is turf for fuel. It makes a tolerable sweet fire, in the common way of using it: and is, when charred, perhaps the sweetest and wholesomest thing that can be burnt, fitter for a chamber, and for consumptive people, than either wood or coal.

"All the inconveniences of our bogs, continues Mr. King, may be remedied, and they may be made useful to us, by draining: for I never observed one bog without a fall sufficient to drain it, nor do I believe there is any. The great objection against this improvement is the expence: in which I cannot but think the people are often terrified without sufficient cause. One trench will drain many acres

Acres in quaking-bogs, which, when dry, are generally meadow, or the best grazing ground. Every red bog has about it a deep, marshy, sloughy ground, which is called the bounds of the bog. A deep trench round such a bog keeps out cattle, and turns the bounds into good meadow. I remember a red bog of sixty acres, which a gentleman reduced to a good grazing ground, worth three shillings an acre, for twenty-five pounds; which is less than three years purchase. In all improvements of this kind, gentlemen should consider, that what they lay out, goes by degrees, so that they scarcely feel it; that it goes among their tenants, whom it helps to enable to pay their rent; that they do a work of charity in employing the poor; and that they at the same time contribute to both the ornament and general profit of the kingdom.

"The deep trench before-mentioned, round a red bog, not only drains and improves the bounds of the bog, as I said before, but goes a great way towards drying the bog itself. It serves likewise as a common sink, into which all the drains vent themselves. These drains should be cut so as to cross the little sloughs that run in the bog. The first drains should not be above two or three feet deep, or wide: for the bog is so soft, that deep trenches will not stand, but fill up again. When the surface of the bog is cut in little trenches, suppose at twenty, thirty, or forty perches distance, it will soon be so dried that cattle may graze on it all the summer. A year or two after this, by which time the bog will somewhat dry towards the surface, the drains may be made six feet wide, and as deep as the softness of the bog will permit. This will certainly make the bog useful for grazing; and at the end of another year or two, an attempt may be made to cut one or two of the trenches down to the bottom of the bog; for till that be done, I do not reckon the bog secured. A gentleman may oblige all his tenants to cut their turf in these trenches, and likewise have his own cut there." *Philosophical Transactions, Numb. 170.*

Small bogs may be turned to very good account by planting them with osiers, willows, and alders: but where the extent is considerable, this object becomes of too little consequence. Draining will be however necessary before they can be improved any other way: as a previous step towards which, it will be necessary to examine from whence their too great quantity of water arises, and what retains it. When the causes are known, their effects will be the more easily removed.

The sources from whence the too great quantity of water proceeds, may either be without or within the bog. This is easily discovered by the greater quantity of water in one place than in another, and observing that the water spreads from thence, even under the surface, as through a sponge.

If the water from without comes from neighbouring grounds, it is usually kept off by a surrounding ditch, made large enough to contain the quantity that may at any time flow down, and by extending that ditch to the most convenient outlet, according to the declivity of the ground. If the bed of gravel or sand through which the springs within the bog run, be cut quite through, the source of those springs will certainly be destroyed; and if that bed be only opened in digging this surrounding ditch, the water will so readily discharge itself thereby, that the springs will probably be dried up.

Before any drain be made in the bog itself, an exact level of the ground should be taken; and when the too great moisture proceeds from a spring or springs within the bog, a large ditch should be made, beginning at the lowest part of the bog, where an outlet can be had, and continued from thence to the spring. If the bog be firm enough to bear it, this ditch should be dug down to the very bottom of the bed on which the peat or moss is formed, which, in case of springs, is always gravel or sand: for otherwise the water would force itself a passage in another part, and so make it necessary to extend the ditch thither. If there be more springs than one, the main ditch must be extended to each of them. In all cases, the surest way is to dig the ditch, where it can be done, at least a foot deeper than the spring lies. Between the principal ditches cut in the bog, there should be smaller, emptying themselves into those larger, to carry off the remnant of stagnating water, and to preserve the surface dry. Care should be taken not to lay the earth dug out of any of these ditches too near their sides, lest its weight should make them fall in.

Bogs are generally higher than the land about them, and

highest in the middle; the chief springs that cause them being generally about the middle, from whence they extend by degrees, and puff up the earth in such a manner, that persons are often apt to think the spring lies deeper than they really do. A sure way to know whether the ditch be deeper than the spring, is to observe whether the water comes in at its bottom, or through the sides. The width of the main ditch should be proportioned to its depth; and both will, in a great measure, depend upon the quantity of water necessary to be drained. In general it should widen progressively from its head to its outlet, because the quantity of water in it will be constantly increased. The sides of the ditch should always be dug either more or less sloping, according to the soil. If the ground be very loose and light, and consequently very liable to fall in, it will sometimes be necessary to make a slope so great, that the top of the ditch will be four times as wide as its bottom. If the soil be stiffer, the slope may be less; but no ditch should ever be dug quite perpendicular.

If a deep trench be cut through a bog, the original spring will be found, vast quantities of water will issue from it, and the bog will subside. Mr. King says that he was informed that the bog at Castle-Forbes, where this was done, subsided thirty feet, a fall which seemed indeed incredible: but he found by computation that it could not be less than fifteen.

Mr. Elliot's contrivance for draining a bog, or what he calls a shaking meadow, containing about forty acres, deserves to be mentioned, for the singularity as well as the usefulness of the invention. The surface of this ground, over-run with cranberry vines and wild grass, seemed to be only a sward of their roots laid over a pappy mud, and was deemed so poor that nobody would rent it. At the ordinary outlet of this meadow, there was a sufficient fall, but very rocky, so that it was necessary to dig four or five feet to take advantage of it. In March, when this gentleman went to make the outlet drain, the torrent of water was so great, that nothing could be done in the usual way. He therefore ordered a tree to be felled across the brook, and pieces of plank, the upper ends of which rested against the tree, to be driven down assant into the mud. The chinks and crevices of these planks were then closely stopped with tow, by which means the water was shut into the meadow. The trench or main ditch was then worked at in the day, and the water let out at night, till the drain was completed. When the weather grew sufficiently warm, and the meadow was a little settled, cross ditches were cut, one on each side, and another in the middle, and, so far as they extended, the meadow soon became firm and dry. "Some, adds Mr. Elliot, are deterred from such an undertaking as that of draining their land, by reason of the great charge. They terrify themselves without reason. When I was about to cut my main drain, some thought it impossible; others, that it would cost, at least, an hundred pounds. The place was full of rocks, some of which we dug up, others were broken with steel wedges, and others were blown up with powder. The whole expence did not exceed twenty pounds." *Essay I. on Field Husbandry, p. 7.*

When the ditches and trenches are finished, great care must be taken to keep them in good and lasting condition, lest all the labour bestowed upon them should be lost.

There are different ways of doing this. If the ditches are left open, they must be well cleansed from weeds and mud, twice every year, once in the spring, and once in the autumn. It will also be right to drive in from space to space, along the inside of their banks, strong stakes of oak or alder, to strengthen them, and keep them from falling in. Willows, which delight in a watery soil, may be advantageously planted upon these banks, which their roots will help to keep up and bind.

If a bog be so entirely surrounded with high grounds, as not to have any declivity whatever, by the help of which its waters may be drained off, ditches must then be dug round it to receive the water from the neighbouring hills, and a very large pond must be made in the middle or lowest part of the bog itself, for its waters to run into; to facilitate which, large trenches should be cut from the surrounding ditches to this pond, and channels communicating with these trenches across different parts of the bog. The number and size of which will depend on the greater or less wetness of the ground. When the water is thus collected, engines must be used to raise it to a proper height for a channel to carry it off. The reader will find a description

of several new and useful engines of this kind under the article, DRAINING MACHINES.

Improvement of drained Bogs. The most lasting and most perfect improvement of bogs, is effected by paring off their surface and burning it. See the articles MOOR and BURNBAKING. In order to this the bogs should be levelled; and whatever earth remains unemployed in filling up hollows, should be burnt together with that taken out of the ditches, unless the latter has been already carried off for fuel. The greater quantity of ashes there is, the greater will be the improvement of the soil itself, and the more will the earth brought upon it be benefited. The fire on the surface of the moss, exhales a very considerable part of the bituminous acid of this soil, and the fixed alkaline salt, always found in some proportion in the ashes, corrects or neutralizes it, so that no inconvenience arises from it afterwards, if the ground be kept dry, as it ought to be. The fire should not be fierce, but rather smothered.

When the bog is pared, and the clods are collected to dry, the farmer must prepare earth to cover the surface. Marle, which is often found under bogs, presents the best covering that can be desired. If a clay lies under the bog, it must be prepared before it is spread in the manner directed under the article COMPOST, excepting only that the quantity of other substances mixed with it, such as dung, &c. need not be so great in this case because the ashes, and the bog itself, will greatly assist in opening the body of the clay. If a loamy earth be near at hand, it will perhaps be less expensive to the farmer to bring such earth to cover the bog, than it will be to dig and prepare the clay. But of whatever kind the earth be, which is laid upon the bog, the quantity should always be sufficient to cover its whole surface four, five, or six inches deep, according to the stiffness of the soil so brought. Thus four inches of clay, when mixed with the ashes, and a due quantity of the earth of the bog itself, will give a depth of covering mould equal to what six inches of loam will do, when likewise mixed in proportion to its quality. If the bog be intended for arable land, the depth of the covering earth should be greater; because all kinds of grain, especially wheat, require at least a foot depth of good mould to extend their roots in, before they come to any cold or tenacious substance like peat or clay. The covering, therefore, of clay or marle should be in this case, six or seven inches thick, and that of loam eight or nine inches.

As soon as the surface is burnt, its ashes should be spread and mixed with the additional covering, which will then be fit for the farmer's purpose, whether for corn or grass. If the extent of the bog intended to be improved be considerable, it should be advisable, by means of a sluice, to fill the ditches contiguous to the spot which is to be covered, and to bring the earth in barges, or flat-bottomed boats, kept on purpose to transport the necessary manures, and the produce of the ground. By this means a saving will be made of the surface otherwise necessary for cart-ways. Besides, this soil, especially, when newly trained, does not well bear heavy carriages; a circumstance which renders it needless to observe, that broad wheels are always the most proper, when any must be used upon such land.

The bog being covered with a proportion of earth, the husbandman must next determine to what lasting purpose he can best apply it. The too great moisture of these soils, which always lie flat, renders them unfit for continued tillage; and their mould becomes so loose, by frequent ploughing, that it does not afford sufficient stability to the roots of corn. For this reason, barley, oats, and rye, do better here than wheat, which requires a firmer footing: but neither of them should ever be sowed thick; because the fruitfulness of the soil will always make up in the size of the plants, what some might think wanting in their number. The most beneficial method of employing this sort of land is, undoubtedly, by converting it into meadow; because, when thus prepared, and not injudiciously exhausted by crops of corn, it will yield great quantities of excellent grass. It is, however, usual to begin with sowing some kind of grain on this prepared surface, to indemnify the farmer by the plentiful crop which it generally yields; such, indeed, as sometimes defrays at once the whole expence of the improvement. Perhaps the most profitable method may be, to sow it in the autumn with rape, the leaves of which, shading the surface in hot weather, and rotting in the winter, contribute greatly to mellow the earth: the strong roots of this plant open the soil; its ashes enrich it, when burnt, and its seed brings a great return when sold for mak-

ing oil. One or two ploughings will then prepare it for a crop of wheat. After this is taken off, and the stubble turned down or burnt, white clover and grass-seed from upland pastures should be sowed, and the ground should then be laid down for a lasting meadow; or, if turneps are sowed, or cabbages planted, in the autumn, these, in the spring, may be succeeded by barley, with which the grass-seeds may be sowed.

When, either through necessity, for want of other arable land, or out of choice, the farmer intends to continue ploughing his improved bog, the surface must be raised in ridges, and the farther management of it may be like that of most other ploughed grounds.

If a soil of this kind happens to be situated near a town, a greater profit will accrue from planting it with garden stuff, than from any sort of grain. Beans, pease, cabbages, potatoes, turneps, carrots, &c. thrive exceedingly well in such earth as this, as the marquis of Turbilly experienced to his entire satisfaction.

"I received, says he, from Strasburg, in the year 1755, some seed of the large hard cabbage, which was immediately sowed in my garden, from whence it was afterwards transplanted into a bog, which I had drained and cleared. This spot contains about an acre of ground, and forms a kind of island in my river. It had been pared and burnt; but never received any other manure than the ashes produced by that burning: no sort of dung having ever been laid upon it. The whole of it was planted with this kind of cabbage, excepting only a corner, where a few carrots, parsnips, and beet-roots all of which grew to a prodigious size; and proved exceedingly good, were set out of curiosity. These cabbages thrived wonderfully, several of them weighing forty pounds a-piece, were well tasted, and very wholesome, though some of the country people seemed positive that they and the other pot-herbs would be hurtful, and unhealthy food, as, said they, all plants are during the first year of their growth in new drained bogs.

"These people pretended to have experienced this in other places; but not finding it so here, I ascribed the effect they talked of to some pernicious quality in the soil; for I was very sure, that the violent operation of the fire which mine had undergone, had not left any bad property in the earth. During the rest of the summer, and the autumn, some of the neighbouring peasants, whom I hired for the purpose, carried this great quantity of cabbages to the markets of three different towns, about six miles off: there they sold them; and the accounts which they gave me of their produce amounted in all to eight hundred and fifty livres, that is thirty-seven pounds, three shillings, and nine pence. The wages of these men and the expence of carriage, amounted to about half this sum; which being deducted, my acre of bog produced clear four hundred and twenty-five livres, that is, eighteen pounds, eleven shillings, and ten-pence halfpenny, with which I was the better satisfied, as the cultivating of it had cost me but little. The soil being light, was easily turned up, though fat; and I had drained off the water without difficulty, by means of a slope which happened to be properly situated. I never had been offered above a crown a year for this marshy land, which was quite a shaking-bog, and often overflowed. When drained, its surface sunk a foot lower than before. So great a produce, from so small a spot of ground, of which no one knew the goodness, shews what vast riches are hid beneath the several bogs in this kingdom. They are not, however, all like this, which chanced to be a very fertile soil. I could wish to be master of several others like it. It has since been sowed with hemp, pease, and several other plants, which have done very well, though none of its crops have produced so much money as this first; which shews the difficulty of setting a just value upon land. All the other bogs which I have drained and cleared in different ways, have answered, in general; but no one ever yielded, in proportion, any thing like this spot." *Mémoire sur les Desfrichemens*, p. 167.

BOG-Spavin, an encysted tumour, or according to doctor Bracken, a collection of brownish gelatinous matter, contained in a bag or cyst, which he thinks to be the lubricating matter of the joint altered, the common membrane that incloses it forming the cyst: this case he has taken the pains to illustrate by an instance of a young colt of his own, where he observes, that when the spavin was pressed hard on the inside of the hough, there was a small tumour on the outside, which convinced him the tumour was within-side the joint: he therefore cut into it, dis-

R charged

charged a large quantity of this gelatinous matter, dressed the sore with daisies dipped in oil of turpentine, putting in to it, once in three or four days, a powder composed of calcined vitriol, alum, and bole: by this method of dressing, the bag sloughed off, and came away, and the cure was successfully completed without any visible scar.

This disorder, according to the above account, will scarcely submit to any other method, except firing, when the cyst should be penetrated to make it effectual; and in all obstinate cases that have resisted the above method, both the cure of this, and the swellings called wind-galls, should be attempted in this manner. If, from the pain attending the operation of dressings, the joint should swell and inflame, foment it twice a day, and apply a poultice over the dressings, till it is reduced. *Bartlett's Farriery, p. 279.*

BOIL, a disease to which cattle, especially sheep, are very subject.

In order to cure these boils, it will be necessary to bring them to a head, by applying to them a plaster composed of wheat-flour, yolks of eggs, and tar: and when they feel soft under the finger, to open them with a lancet, and let out the matter. Then anoint the part with ointment of tobacco, and apply over it the following plaster. Take of turpentine, burnt salt, honey, and galbanum, of each one ounce; of rosin an ounce and a quarter. Melt the whole into a salve over the fire. *Ellis on Sheep, p. 101.*

BOLE signifies the stalk or stem of corn.

BOLE, a measure of corn, containing four bushels.

BOLE of Salt, contains two bushels.

BOLING-Trees, pollard trees, or those whose heads and branches are cut off, and only the boles or bodies left.

BONE, a hard, brittle, insensible part of an animal body, affording form and support to the whole machine.

All marrow-bones, fish-bones, hoofs, horns, or shavings of horn, are very useful in manuring lands. Bones are most serviceable when rasped or broken into small pieces; because their salts, in which their principal virtue consists, are more easily extracted by the rains and dews, and communicated to the soil.

Mr. Young, in his third volume of his *Annals of Agriculture*, says, that bones have the superiority of all manures. It is a manure not uncommon in Middlesex and Surry; all are brought from London, where are people who make it their business to collect and break them into small pieces, for those who boil them for the grease; this operation one would suppose would leave them of not much value, but the contrary is the fact. When I found by this and other trials, that their effect was so very great, I bought all I could get; the price 10s. 6d. a waggon load at London, of 96 bushels, which, by the time they were on the farm (for I generally went on purpose for them) amounted from 25s. to 30s. a load. Five and twenty cart loads in this trial being superior to 50, was owing to the latter quantity being too great a dressing. For this miserable soil, which with a summer fallow had before yielded but 30 bushels, to produce 63 by a moderate manuring of bones, shews their amazing effect.

BONE-Spavin, a boney excrescence, or hard swelling growing on the inside of the hock of a horse's leg.

A spavin that begins on the lower part of the hock, is not so dangerous as that which puts out higher, between the two round processes of the leg-bone; and a spavin near the edge, is not so bad as that which is more inward towards the middle, as it does not so much affect the bending of the hock. A spavin that comes by a kick or blow is at first no spavin, but a bruise on the bone or membrane that covers it; therefore, not of that consequence, as when it proceeds from a natural cause: and those that put out on colts, and young horses are not so bad as those which happen to horses in their full strength and maturity; but in very old horses they are generally incurable.

The usual method of treating this disorder, is by blistering and firing, without any regard to the situation or cause, from whence it proceeds. Thus if a fullness on the fore-part of the hock comes after hard riding, or any other violence which threatens a spavin, such coolers and repellers are proper as are recommended in strains and bruises. Those happening to colts and young horses are generally superficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by severe means.

There are various forms for making what is called the blistering ointment; but of the best of that kind, and what will infallibly answer the intention, has been already given under the article **BLISTERING OINTMENT**.

When a blister is thought necessary, the hair should be cut as close as possible, and then the ointment applied pretty thick over the part; this should be done in the morning, and the horse kept tied up all day without any litter till night; when he may be untied in order to lie down; and a plaster of pitch, or any other sticking substance, may be laid over it, and bound on with broad tape, or a bandage, to keep all close.

After the blister has done running, and the scabs begin to dry and peel off, it may be applied a second time in the same manner as before; the second application generally taking greater effect than the first, and in colts and young horses makes a perfect cure.

When the spavin has been of long standing, it will require to be renewed perhaps five or six times; but after the second application, a greater distance of time must be allowed, otherwise it might leave a scar, or cause a baldness; to prevent which, once a fortnight, or three weeks, is often enough; and it may in this manner be repeated six or seven times, without the least blemish, and will generally be attended with success.

But the spavins that put out upon older, or full aged horses, are apt to be more obstinate, as being seated more inward; and when they run among the sinuosities of the joint, they are for the most part incurable, as they then lie out of the reach of applications, and are arrived to a degree of impenetrable hardness.

The usual method in these cases is to fire directly, or to use the strongest kind of caustic blisters; and sometimes to fire and lay the blisters immediately over the part; but this way seldom succeeds farther than putting a stop to the growth of the spavin, and is apt to leave both a blemish and stiffness behind; besides the great risk run (by applications of these fiery and caustic medicines, to the nervous and tendinous parts about the joints) of exciting violent pain and anguish, and destroying the limb.

The best and safest way therefore is to make trial of the blistering ointment given under that article, and to continue it according to the directions above laid down, for some months, if found necessary; the horse in the intervals working moderately; the hardness will thus be dissolved by degrees, and wear away insensibly.

When the spavin lies deep, and runs so far in the hollow of the joint, that no application can reach it, neither firing nor medicines can avail, for the reasons above-mentioned: though bold ignorant pretenders have sometimes succeeded in cases of this sort by the application of caustic ointments with sublimate, which act very forcibly, enter deep, and make a large discharge; destroying by that means a great part of the substance, and dissolve away the remainder. Though whoever is at all acquainted with the nature of such medicines, must know how dangerous in general their operation is on these occasions, and that a properly prepared cautery made like a steam, under the direction of a skilful hand, may be applied with less danger of injuring either tendons or ligaments. After the substance of the swelling has been properly penetrated by the instrument, it must be kept running, by precipitate mixed with the medicine used in dressing the part, or with a mild blistering ointment.

Where the spavin lies not deep in the joint, and the blistering method will not succeed, the swelling may be safely fired with a thin iron forced pretty deep into the substance, and then the part should be dressed as above directed. *Bartlett's Farriery, p. 257.*

BOORCOLF. See **BORECOLE**.

BOOSE, a stall. Thus ox-boose signifies an ox-stall, &c.

BORECOLE, or **BOORCOLF**, a species of cabbage, of which there are three sorts, namely, the common borecole, the green borecole, and the Siberian borecole, which is the curled colewort, by some called Scotch kale. All these are for winter use, but the last is most esteemed. The two former are sown about the middle of April, and are fit for transplanting in about two months after. When this is done, the plants of either of these sorts should be set a foot asunder in rows two feet distant from each other. They should not be eaten before the frost has rendered them tender; for till then they are tough and bitter. The Siberian borecole, which is extremely hardy, never injured by frost, and always sweeter in severe winters than in mild ones, need not be sown till the middle of July, and when the plants are strong enough for removing, that is when they have six or eight leaves, they should also be set in rows; the distance between which should be about two feet, and that between the plants, ten inches. These will be fit for use soon after Christmas, and continue good till April. The

The soil for borecole should be a good, fresh, deep-loosened earth.

Borecole has been lately found by Mr. John Wynn Baker to be an excellent food for cattle; and the Society for the Encouragement of Arts has accordingly offered two premiums for cultivating it, one of twenty, and the other of fifteen pounds.

Mr. Baker made the experiment under the direction of the Dublin Society, who desired him to print his account of the experiment, an abstract of which we shall give the reader.

This experiment was made on a piece of ground that had been cropped the preceding year with potatoes. After he had reduced the soil to a pretty good tilth, and manured it with a compost composed of earth, lime, and dung, he planted three rows of borecole plants, in ridges two feet asunder. On the 17th of August they were horse-hoed for the first time, by taking off, at one furrow of the plough, only one side of each ridge close to the plants; in which manner they remained till the twenty-fifth, when he ran the plough in the same furrow, by which with the first furrow, he ploughed about twenty-one inches deep. This being finished, the earth was immediately returned back to the plants, which afforded them fresh nourishment; and in order to give their roots time to penetrate this fine earth, which, by the horse-hoeing was become every fine mould, he let them remain in this state till the 12th of September, when he horse-hoed them again, by taking off the other side of every ridge; and on the twentieth deepened the furrow in the same manner as the former, and immediately returned the mould back to the plants; and on the eighteenth threw up a small furrow to each side of every ridge, which finished the culture, and restored the ridges to the form they were in when the borecole was planted.

"On the 18th of December, continues Mr. Baker, I cut two perches in length of one of the rows of borecole, which contained twenty-one plants; they weighed one hundred and eighteen pounds, which is very near five pounds ten ounces for each plant: but I am inclined to believe that these plants will succeed as well, if they are planted only eighteen inches asunder in the rows. However, at the above proportion, there would be seventeen tons, and fourteen hundred upon an acre. But, if the produce would be same, were the plants only eighteen inches asunder, in that case, an acre would produce, by this culture, above twenty-three tons, and twelve hundred.

"This plant is worthy the farmer's or grazier's attention, for, as fast as it is cut, it will again, in about a month or six weeks, afford another crop: I have been cutting these plants for my family use, ever since the middle of August last; I believe some of them have been cutting three times, and they are excellent for the table. For feeding cattle and sheep they are highly valuable, as no frost will injure them; and although the first crop amounts not to as many pounds upon any given quantity of ground as those of cabbage or the turnep cabbage, yet the succeeding crops will, I believe, make their produce nearly, or quite, of equal weight with any other of the cabbage kind. But I must not omit to observe, that, as these plants afford only open leaves, and many of them very small, there will be a little more trouble in collecting and carrying them to the sheep and cattle, than there will be with the other kinds.

"It may not be improper to observe likewise, that, upon the approach of spring, when they begin to throw out their spring shoots for seeds, if the large leaves have not been taken off for winter use, they will decay and fall off.

"I have not yet tried it; but I believe the best way of using this plant, would be to allot one whole field to the culture of it, proportioned in size to the stock intended to consume the produce: and in September or October, to turn the ewes into the field for a few hours, morning and evening, and then to lodge them on any piece of grass or fallow, which may want improvement, to which they will greatly contribute by emptying themselves upon it; and thus continue to turn them into the borecole-field, till they have eat all the luxuriant leaves; then let the plants rest a month, and there will be another crop. By having two small fields under this crop, a flock of store sheep might be maintained a whole winter at a very small expence; for while the produce of one field would be consuming, the other would be coming on.

"This method occurred to me from an accident which attended my borecole this year. My cows got into the field, and presently devoured some of the leaves of the plants;

these plants have engaged my attention ever since, and I have the pleasure of seeing them again in a very luxuriant state.

"If any persons should be able to put this scheme in practice, before I can accomplish it, I recommend it to them not to let the sheep pasture so long on the crop, as to injure the stalks for want of leaves, as too great an injury to the stalks may check the succeeding growth; which injury, I am inclined to believe, will not happen to the plants, at least not in so great a degree, whilst they have a sufficient quantity of leaves.

"It will doubtless be observed, that I confine this scheme to ewes or store-sheep: my reason for that is, that fat sheep should always have as much food before them, as they choose to eat; add to this that sheep when they are fat, are more subject to be lame than store-sheep, to which ploughed ground will greatly contribute."

BORD-Lands, the demesnes which lords keep in their own hands, for the maintenance of their board or table.

BORD-Service, the tenure of board-lands, by which the tenants were to provide provisions for their lord's tables. There is still some remains of this tenure remaining; but the tenants pay only a small rent per acre, instead of finding the provisions formerly required.

BORER, or *Screw-borer*, an instrument invented by the marquis of Turbilly, for searching or exploring the nature of any soil.

This borer is composed of two rods of iron, Plate I. fig. 6 and 7, each six feet long, and an inch in diameter. The end A, of fig. 6, screws into the end B, of fig. 7, after taking out the stopper C, the use of which is to hinder either dirt or dust from getting into the screw. The screw is an inch and a half long, and three quarters of an inch in diameter. D, fig. 6. is a steel point somewhat blunt to pierce the earth, or any substance it may meet with. It should be about three inches long, and made with either three, four, or more sides, as may be thought most convenient. It is screwed into the rod A in the same manner, and with a screw of the same size as A is screwed into the rod B. It is a groove six inches long, a third of an inch wide, and three quarters of an inch deep, rounded in the bottom, and intended to bring up part of each different layer through which it passes. When springs are sought for, a bit of sponge is put into the groove. At the end F, of the rod, fig. 7, is a screw to fix into another rod of the same kind, if it be found necessary to lengthen the instrument; and this may be repeated by the addition of more rods, to any depth desired. G H, fig. 6, is the handle of this instrument two feet and a half long. This handle is fastened to the rod by means of a clasp I, lined with steel, fixed at one end by a hinge, and at the other by the screw L; so that it may be placed at any height. Fig. 8. is the handle separated from the rod, and marked with the same letters as before. Fig. 9. marked with the same letters as before, is another handle, or rather lever, like the handle already described, except its having only one branch or lever marked G. This serves to stop the borer when we are bringing it up from a considerable depth, and also to screw and unscrew the several bars, or joints, as occasion requires; and to put on, or take off the steel point at the bottom. The handle G A, fig. 6. is that by which the rod is held, and worked into the earth, either by twisting it round, especially at first, or after it has penetrated to the same depth, by lifting it up, and letting it fall again, which it does with such force, as to pierce even the hardest rocks; especially if it works at any considerable depth, and has of course been lengthened accordingly; for every foot of this rod weighs three pounds. Two men will easily found the depth of twelve feet in less than a quarter of an hour, if they do not meet with many stones. When the rod becomes too heavy to be properly managed by hand, it may be raised by a rope fastened at one end to the handle, and at the other to a roller, or kind of windlass, erected at a proper height, perpendicularly over the hole, and turned with either one or both handles. This will cost but a trifle, and will easily raise the other rod, which, when let go, will fall with such weight, as to strike each time very deep into the earth. The marquis tells us, that he has seen it worked in this manner to the depth of more than an hundred feet.

The toughest iron is the best for making this instrument which should be well hammered, till its surface be quite smooth and even; for the least roughness and inequality would occasion a friction, which would greatly retard its working. For the same reason, and also to increase the force

force of its fall, it is necessary that it should be perfectly straight, nor should it ever be struck with a mallet, hammer, &c. to force it down; because a blow might bend it, and it would easily break afterwards. The female screw must be turned like that in the breech of a gun barrel, in a separate piece of iron, cross-ways to the grain, and this piece must be afterwards well foldered on to one of the ends of the rod. The reason for this is, that if the female screw were bored only at the end of the rod, it would, by being hammered out in the same direction with the grain, be stringy and porous, and consequently so weak as to give way, or burst, in the working of the rod; whereas, when made of a separate piece, taken cross-ways of the grain, the threads of the screw will run with the grain of the iron, and be thence considerably strengthened. A bit, like that of an augre, proportioned to the thickness of the rod, may at any time be substituted instead of the steel point, to draw up a sample of the substance from the very bottom of the sounding.

If the only thing wanted be to know the nature of the under soil, and layers of earth, so far as they may effect the vegetation of plants, it will be very sufficient to bore eight or ten feet deep. A greater depth is only requisite when water, marl, ore, &c. be sought for.

The common auger indeed will do very well for shallow boring, as we have already observed under that article. See the article AUGRE.

By either of these instruments, there is a certainty of discovering, without much charge, or any hazard, not only what earths are under the upper soil, but also whether any other substance of value lies concealed there, such as marle, chalk, fuller's earth, fossile shells, coals, quarries of slate or stone, ores, &c. many of which are hid, and intirely unthought of in places, where their value, was it known, is ten times more than that of the estate which covers them.

BORING, an operation sometimes practised for the cure of horses, whose shoulders are wrenched.

The operation is performed in the following manner: they cut a hole in the skin in the middle of the shoulder, and with the flank of a tobacco-pipe, blow it as a butcher does a shoulder of veal; then they run a cold flat iron, like a horseman's sword-blade, eight or ten inches up between the shoulder blade and the ribs, which they call boring; after that, they burn him round the shoulder with a hot iron. *Burd. Gent. Far.*

This is a very absurd and cruel treatment, and can be of no manner of service. *Bartlet's Farriery.*

BOTTS, a name given to a species of worms infesting horses and other cattle.

The botts which grow in the stomach of horses, and which are sometimes the cause of convulsions, appear to be very large maggots, composed of circular rings, with little sharp prickly feet along the sides of their bellies (like the feet of hog-lice) which by their sharpness, equal to that of the finest needle, seem to be of use to fasten them to the part where they breed, and from whence they draw their nourishment, and also to prevent their being loosened from such adhesion, before they come to maturity. The eggs from whence these botts are produced, are disposed in clusters round the lower orifice of the stomach, and are layed under the inner coat, or thin membrane of the stomach; so that when the animals come to life, they burst through this inner coat, their breech and tail strait outwards, and their trunks so fixed into the muscular or fleshy coat of the stomach, that it sometimes requires a good pull to disengage them: from the blood of this last coat they draw their nourishment, which they suck like so many leeches, every one ulcerating and purfing the part where it fixes, like a honey-comb; and they often make such quick havock as to destroy the horse.

The botts which many horses are troubled with in the beginning of the summer, are always seen sticking to the straight gut, and are often thrust out with the dung, together with a yellowish coloured matter resembling melted sulphur; they are no ways dangerous there, but are apt to make a horse restless and uneasy, and rub his breech against the posts. The season of their coming is in the months of May and June, after which they are seldom to be seen, and rarely continue in any one horse above a fortnight or three weeks. And the creature may be easily cured when they are only in the straight gut, by given him a spoonful of favin cut very small, once or twice a day in his oats, or bran, moistened; three or four cloves of garlick may also be

added to advantage. The following purge should likewise be given:

Take fine succotrine aloes ten drams; fresh jallap one dram; birthwort and myrrh powdered, of each two drams; oil of favin and amber, of each one dram; syrup of buckthorn enough to form the whole into a ball.

But the botts, which take their lodgment in the stomach, are, as has been already observed, extremely dangerous, by causing convulsions, and are seldom discovered by any previous signs before they come to life, when they throw the horse into violent agonies. The only cure for these is mercurial medicines; the following will answer the intention:

Take quicksilver two drams; Venice turpentine half an ounce; rub the quicksilver till no glistening appears; then take an ounce of aloes, a dram of grated ginger, thirty drops of oil of favin, and syrup of buckthorn enough to make the whole into a ball.

One of these balls may be given every six days, with the usual precautions with regard to mercurial physic: and the following powders immediately:

Take powdered tin and Æthiops mineral, of each an ounce; and give it every night in a mash, or in his corn.

These medicines, or any of the various preparations of antimony and mercury, should be continued several weeks together, in order to free the animal entirely from these vermin. *Bartlet's Farriery, p. 150.*

If the horse is tender and weakly, and feeds but poorly, give him the following stomach drink.

Take gentian root, six ounces; camomile flowers, two hanfuls; Peruvian-bark, two ounces; filings of iron, half a pound; juniper berries, four ounces; infuse them six or eight days in three gallons of ale, shaking the vessel now and then; after which give a pint of the clear liquor two or three times a day.

If the horse is robust, but hath worms, from full but bad feeding, give him, with his corn, a handful of rue, garlic, tansey, favin, and other such-like vegetable. Some have ventured to give half an ounce of cut tobacco with the corn, once a day, for two or three weeks.

The round worms are generally destroyed with filings of tin; joined with bitters and a purge now and then thus:

Take the filings of tin, and myrrh, of each half an ounce; make them into a ball with honey, and repeat it twice a day. But before giving this ball, give a purging ball with aloes, and repeat it once in eight days.

If any come away dead, you may conclude that they are all killed.

But of all the species, bott worms are the worst, particularly if they are in the stomach, those in the guts being rather troublesome than dangerous. To destroy the botts in the stomach, calomel should be first given, and that freely; but as the convulsions soon shut up the horse's mouth, and, usually, there are no preceding symptoms to warn you before the violent attack, therefore if botts are any way suspected, lose no time, immediately get down the following bolus:

Take calomel and London philonium, of each half an ounce; honey, enough to make a bolus; and, if possible, repeat a lesser dose, in four or five days, and a common purging ball the day following.

Botts in the straight gut are easily destroyed by giving a large spoonful of favin twice a day in bran or corn, a little moistened, and an aloetic purge at proper distances from each other.

Both common salt and saltpetre are very efficacious in cases of worms, particularly against species not yet mentioned, and that in some counties are called needle-worms; they are slender, about an inch long, of a yellowish colour. Two ounces of either of these salts may be given every night in a mash or any other convenient method, for two or three weeks.

With regard to other kinds of worms, the above medicines will also be sufficient.

You may also add three or four cloves of garlic, and a purge of aloes.

BOUDS, a name in some countries for the insects generally called weevils, breeding in malt.

BOWS of a saddle, are two pieces of wood laid archwise to receive the upper part of the horse's back, to give the saddle its due form, and keep it steady.

BOX, the name of a well known tree, of which botanists enumerate seven species, viz. 1. The box-tree. 2. The narrow-leaved box-tree. 3. The striped box. 4. The gold-edged box-tree. 5. The dwarf box. 6. The dwarf striped box. 7. The silver-edged box.

The first and second sorts grow in great plenty upon Box-hill, near Dorking in Surry, where were formerly large trees of these kinds; but of late they have been pretty much destroyed: yet there are great numbers of these trees remaining, which are of a considerable bigness. The wood of this tree is very useful for turners, engravers, and mathematical instrument makers; the wood being so hard, close, and ponderous, as to sink in water; which renders it very valuable for divers utensils.

All the varieties of the trees, or large box, are proper to intermix in clumps of evergreens, &c. where they add to the variety of such plantations: these may be propagated by planting the cuttings in autumn in a shady border, observing to keep them watered until they have taken root; when they may be transplanted into nurseries, till they are fit for the purposes intended. The best season for removing these trees is in October; though, indeed, if care be used to take them up with a good ball of earth, they may be transplanted almost at any time, except in the summer: these trees are a very great ornament to cold and barren soils, where few other things will grow; they may also be propagated by laying down the branches, or from seeds: the last being the best method to have them grow to be large, the seeds must be sown soon after they are ripe, in a shady border, which must be duly watered in dry weather. *Miller's Gard. Dict.*

Box of the wheel, the aperture wherein the axis turns.

Box of a plough, the cross-piece in the head of a plough which supports the two crow-staves. See **PLOUGH**.

BRACE, a general name for a couple, or pair of any thing, as bucks, hounds, partridges, &c.

BRACKEN, the same with brakes, or fern. See the article **FERN**.

BRAKE, the same with fern. See the article **FERN**. It is likewise applied to the place where fern grows.

BRAKE, is also a name given to an instrument often used by farriers, &c. generally called barnacles. See **BARNACLES**.

BRAKE, is likewise the name of a wooden-toothed instrument used to bruise and break the bun of hemp, and separate it from the rind. See the article **HEMP**.

BRAMBLES, in **FENCING**. Mr. Young, in his *Annals of Agriculture*, vol. II. gives the following letter from Mr. Le Blanc, of Cavenham in Suffolk, on their utility, viz. "You will be surprised that a practical farmer should venture to recommend the culture of the bramble, a plant universally looked upon as a very troublesome weed. I, nevertheless, think it worthy the attention of every man who wishes to raise live hedges in a poor sandy soil, in the shortest time, at the least expence. The idea of the utility of brambles first struck me from the following circumstances: several small enclosures were made in this parish (which you well know is a blowing sand) about eleven years ago, on each side of a narrow field-road, in which a large flock of sheep was frequently driven; on one side of the road the bank was planted with brambles mixed with the white-thorn, and a dead hedge placed on the top, as is the usual method in this country; the dead hedge has never since been renewed, and the fence is now a tolerably good one. The bramble, which is a very fast grower, not only defends the young quick from the sheep, but likewise by twisting itself through the dead-hedge, strengthens it, and prevents it from being broken down either by cattle or pilferers. On the other side of the road, the bank was planted at the same time, and in the same manner, with white-thorn only. The dead-hedge has been renewed several times, and there is at this time no probability that the white-thorn will ever make a fence. I have not been unmindful of the hint which the above observations suggested to me, but made what I think an improvement upon it, by planting two rows on the bank; the lower one of bramble

only, the upper one of white-thorn only. I have tried this method in the years 1781 and 1782, and both fences are now much more promising than I could have expected them to be if planted with white-thorn only. You will observe, that I do not recommend this plant, but in poor sandy soils, where the growth of quick-hedges is slow; where they are liable to the depredations of sheep; and where, by reason of the looseness of the soil, the ditch is no defence."

BRAN, the skin or husks of corn, especially wheat, ground and separated from the flour by means of a sifter or boulder.

Bran is a useful ingredient in a horse's diet, if discretely used, and when scalded is a kind of panada for sick horses. But nothing is worse than a continual use of bran, raw or scalded, as it is apt to weaken a horse's bowels, and thereby expose them to many disorders. *Gibson on the Diseases of Horses*, vol. I. p. 172.

Mr. Mills assures us, that a little wheat-bran boiled in our ordinary beer, will make it mantle in the cup. *Husbandry*, vol. I. p. 407.

BRANCH, an arm of a tree, or a part which, sprouting from the trunk, helps to form the head or crown.

BRANK, the same with buck-wheat. See the article **BUCKWHEAT**.

BRAWN, the flesh of a boar, boned, rolled up, or collared, boiled, and lastly pickled.

Brawn is made only of the flitches, without the legs: the oldest boars are chosen for this use, it being a rule, that the older the boar the more horny the brawn.

The method of making it is as follows: the bones being taken out of the flitches, the flesh is sprinkled with salt, and laid in a tray, that the blood may drain off; after which it is salted a little, and rolled up as hard as possible. The length of the collar of brawn should be as much as one side of the bone will bear; so that when rolled up, it may be nine or ten inches in diameter.

The collar being thus rolled up, it is boiled in a copper or large kettle, till it is so tender that you may run a straw through it; when it is set by till thoroughly cold, and then put into the following pickle; to every gallon of water add two handfuls of salt, and as much wheat-bran; boil them together, drain the liquor as clear as possible from the bran, and when the liquor is quite cold, put the brawn into it.

BREAD, a well-known food, chiefly divided into white, wheaten, and household; differing only in degrees of purity. In the first, all the bran is separated; in the second, only the coarser; in the third, none at all; so that fine bread is made only of flour; wheaten bread of flour, with a mixture of fine bran; and household, of the whole substance of the grain, without taking out either the coarse bran or fine flour.

We also meet with symnel-bread, manchet, or roll-bread, and French bread; which are only so many denominations of the finest or whitest bread, made of the purest flour; except that in roll-bread there is an addition of milk, and, in French bread, of eggs and butter also. To which may be added, ginger-bread, made of white bread, with almonds, liquorice, aniseed, rose-water, and sugar; and massin-bread, made of wheat and rye, or sometimes of wheat and barley.

The process of making household bread among us is thus: to a peck of meal they add a handful of salt, a pint of yeast, and three quarts of water, cold in summer, warm in winter, and temperate between the two; the whole, being kneaded in a bowl or trough by the fire, in winter, from it in summer, and a little yeast added, will rise in about an hour; they then mould it into loaves, and put it into the oven to bake. *Hought. Collect.*

For leavened bread, part of the flour intended for it, being made into dough with warm water and a little salt, is laid in the rest of the flour an hour or more, in which time it rises to three times the bulk; then they mix and knead the whole with more water, till it be brought into a stiff dough; which being formed into loaves, is baked in the oven: though the more usual way is to take a piece of dough kneaded, and leave it in the tub till next time, when they break it small, and mix it with the meal, adding some yeast. *Hought. Collect.*

For French bread, they take half a bushel of fine flour, ten eggs, and a pound and a half of fresh butter, into which they put as much yeast, with manchet; and, tempering the whole mass with new milk, pretty hot, let it lie half an hour

to rise; which done they make it into loaves or rolls, and wash it over with an egg beaten with milk; care is taken the oven be not too hot. *Rust. Diet.*

BREAD for horses: horses are sometimes fed with bread, to hearten and strengthen them: the way to make the same is two-fold:

1. Take wheat-meal, oat-meal, and beans, all ground very small, of each a peck; aniseed, four ounces; gentian and fenugreek, of each an ounce; liquorice two ounces; all beaten into fine powder, and searfed well: to which add the whites of twenty new-laid eggs, all well beat, and as much strong ale as will knead it up: then make your loaves like the house-bread, but not too thick; and let them be well baked, but not burnt; give it not too new; and let him have it five or six mornings together, without any other provender.

2. Take of wheat-meal, rye-meal, beans, and oat-meal, of each half a peck, ground very small; aniseed and liquorice, an ounce of each; and white sugar-candy, four ounces: beat all into a fine powder, with the whites and yolks of twenty new-laid eggs, well beaten; and put to them as much white-wine as will knead it into a paste; which then make into great loaves, and bake them well: when two or three days old, give him to eat thereof, but chip away the outside.

For race-horses, there are three sorts of bread used; given successively, for the second, third, and fourth fortnight's feeding. 1. Take three pecks of clean beans, and one peck of fine wheat; mix them together, and grind them into pure meal; that done, bolt it pretty fine, and knead it up with good store of fresh barm, but with as little water as possible; labour it well in a trough, break and cover it warm, that it may swell; then knead it over again, and mould it into large loaves, in order to be well baked. When they are drawn from the oven, turn the bottom upward, and let them cool: at three days old you may give your horse this bread, but no sooner; as nothing is more apt to surfeit than new bread. Or you may,

2. Take two pecks of clean beans, with two pecks of fine wheat, and grind them well together; then bolt and knead it with barm, or lightening, and make it up as you did the former bread. With this bread, having the crust cut quite away, and oats, or split beans, mingled together, or separately if you think fit, feed the horse as before, at his usual meals. Or,

3. Take three pecks of fine wheat, and one peck of beans; grind and bolt them through the finest bolter you can get; then knead it up with new strong ale and barm, beat together, and the whites of twenty eggs, or more, and no water at all; but instead thereof a small quantity of new milk: at last work it up, bake and order it as the former; and with this bread, having the crust cut off, adding clean oats and split beans, all mixed, or separate, feed your horse at his ordinary feeding times, as you did in the fortnight before.

BREAK, land ploughed the first time after it has lain fallow in sheep walks.

BREAKING-UP. See **SOD-BURNING**.

BREASTS, part of the bows of a saddle. See **BOWS**.

BREAST-PLATE, or **TREE**, is the strap of leather that runs from one side of the saddle to the other, over the horse's breast, in order to keep the saddle tight, and hinder it from sliding backwards when the horse goes upon a rising ground.

BREAST-PLOUGH, a small plough, contrived so that a man may shove it before him. It consists of a cutting-iron about eight or nine inches long, and having one of its sides turned up to cut the turf. This iron is fixed to a pole bending upward about five or six feet long, and forked at the upper-end, having a crutch, or cross handle, mortised into the forks. Against this crutch the ploughman places his breast, and shoves along the plough, in order to turn up the turf, its only use being for cutting up the surface of the ground in the operation called burn-baking. See the article **BURN-BAKING**, and **SOD-BURNING**.

BRECK, or **BRACK**, a breach or gap made in a hedge.

BREEDING. See **CATTLE**.

BREW-HOUSE, a house erected for the purposes of brewing.

The conveniency of water is one of the first things to be attended to in erecting a brew-house, because the frequent carriage of that necessary fluid greatly enhances the cost of the beer. The water should be soft, and if supplied from an adjacent river, it should be conveyed by a passage under-

ground, in order to its being pumped up from thence into the copper, or into troughs properly placed for carrying it where it may be wanted. If there be a reservoir for rain-water, it should be made as near the brew-house as possible.

The quality of water made use of, is a principal consideration in brewing: and to this, in a great measure, seems to be owing the superiority of the beer of some particular places. Ramsbury, in Wiltshire, is noted for good beer, which induced a brewer in a neighbouring county to imitate it; and being of opinion that the goodness of the Ramsbury beer was chiefly from a superior quality of the malt brewed there, he bought some of the best malt to be had there, but found upon trial, that the beer brewed from it, was no better than what he used to brew from other good malt. He then bought some more malt at Ramsbury, and engaged a brewer from thence, to brew this malt for him; but without success: this second brewing of the Ramsbury malt was no better than the first, which induced him to conclude, that the superior quality of the Ramsbury beer consisted principally in their water; which is softened by the chalk washed down from the higher grounds there, by rain. In confirmation of which, it is observable, that a brewer in Ramsbury removed some years ago to Whitchurch in Oxfordshire, where he continued to brew beer, and the soil of that neighbourhood, being also chalky, his beer so much resembled the Ramsbury beer, that he sent quantities of it to London, and sold it there as such.

Water for brewing is softened, not only by chalk, but by other calcareous substances, which may be obtained in many places at proper seasons. The late Mr. Owen, who kept the Rummer at Charing-Cross, London, was noted for the goodness of his beer, which he had from Mr. Gyfford's brew-house. The reason he assigned for his beer being so good was, that he laid in his stock of beer in the month of November, immediately after hard rains that flooded the river, and made the water muddy; his beer was then brewed, and as soon as it was in fit order, was all put into his cellars at Charing-cross, where he attended to its fermentation himself; and declared he knew no other reason for the good quality of his beer, but the quality of the water, thus softened by the particles of the soil, washed into the river by the first heavy rains that fell in the beginning of winter; a circumstance worthy of the notice of those who are desirous to have very good beer, which their attending to this circumstance may be a mean of obtaining, without any additional expence.

The brew-house should be so situated as to face the north, for shade and coolness. It should be as near as possible to the cellar, that the labour and expence attending the carriage of the liquor may be saved, and the danger of exposing it to either too hot or too cool an air prevented. The floor should be paved with stone or hard bricks, and raised in the middle, to give an easy discharge to the water, so as to keep the brew-house always clean.

The copper should be proportioned to the quantity brewed, and should be raised so high that the water may run from it to the mash-tub, and the wort to the coolers. For this purpose there should be either a cock in the side, at the bottom of the copper, or a brass pump should be fixed to its side, by means of which the water or wort may be conveyed through a trough to their proper receptacles.

The mash-tub should be round, not too deep, and perfectly smooth on the inside. It should have a false bottom, which may serve as a strainer, when, by turning a cock placed below, the wort may be drawn off into the receiver: or the wort may be let out by means of an upright plug, surrounded with a basket-strainer.

The receiver should be lined with milled lead, which is easily kept perfectly clean, and is not apt to contract any bad taste or sent, as wood is known to do, notwithstanding the greatest care. The best method of conveying the wort from the receiver to the copper is by means of a hand-pump.

There should be two coolers, or backs, as the brewers call them. These should also be lined with milled lead, or made of the heart of oak, rendered perfectly smooth; and placed as near as convenient to the copper.

The working vessel or tun should be placed at some small distance from the cooler. It should be round, but not lined with lead; because this would cool the liquor too much in cold weather during the fermentation.

The cellar should, as already observed, be near, if possible, and sunk much lower than the working-tun, that the beer

beer may be conveyed into the casks by a cock and hose, or some other easy method.

There must be in the brew-house an oar to stir the malt in the mash-tub, with bowls, pails, and other utensils, necessary in different operations. These, as well as every other implement employed in brewing, should be boiled in the copper, or well scalded every time, before they are used.

Too great care cannot be taken to keep every vessel perfectly clean and sweet: for if they are the least tainted, the liquor will contract a disagreeable scent. When any taint is suspected, the vessels should be well washed with a strong ley of clean wood-ashes. This ley should be put into them, scalding hot, and every joint, crevice, and smallest hollow, must be well scrubbed. If there are no ashes to be had, lime may be flaked in water in the vessels; and if this be done in casks, they may be bunged up as soon as the ebullition is over, and not opened till three days after. The more effectually to prevent the lodging of any kind of filth, the sides of every vessel should be as smooth as possible; and after every brewing, they should be washed with boiling water, and laid up dry.

BREWING, the operation of preparing beer, or ale, from malt and hops.

The usual process of brewing is as follows: the ingredients being ready, the water must be made to boil very speedily, and while boiling with the greatest violence, the fire must be immediately damped, or put out; when the height of the steam is over, the water is put into the mashing-but, to wet the malt; then so much being poured out, as to make it of a consistence stiff enough to be rowed up, let it stand thus a quarter of an hour, after which another quantity of water is added, and rowed up as before; at last, the full quantity of the water is poured upon it, and that in proportion as the liquor is intended to be strong or weak: this part of the operation is called mashing. Afterwards the whole may be left to stand two or three hours, more or less, according to the strength of the wort, or to the difference of the water; then let it run into the receiver, and mash again for a second wort, in the same manner as for the first, only the water must be cooler, and must not stand above half the time.

The two worts being mixed together, the quantity of hops that is designed may be added thereto, and the liquor put into the copper, which being closely covered up, let boil gently for the space of an hour or two; then let the liquor into the receiver, and the hops strained from it into the coolers.

When cool, the barm is applied; which done, it is left to work, or ferment, till it be fit to tun-up.

For small-beer there must be a third mashing; the water must be near cold, and to stand not above three quarters of an hour; to be hopped and boiled at discretion.

Such is the process, as commonly delivered, for brewing; but it is in many particulars so vague and uncertain, that proper explanations will be requisite.

The malt is ordered to be put into the mash-tub, when the height of the steam is over: but how is this to be known exactly? Some direct you to stay till you can see your face in the water, which is full as equivocal. Perhaps the method proposed by Dr. Shaw might answer the purpose. He directs us to put a certain measured quantity of cold water to the malt first, and stir that very well with it, so as to form a kind of thin uniform paste; after which the remaining quantity of the water may be added in a state of boiling, without the least danger. By this means, adds that able chemist, the proper or precise degree of heat, necessary to extract the virtue of the malt with all advantages, may be very expeditiously hit, or assigned, to a great exactness; as the heat of boiling water is a standard, which may at once be let down to any desired point of warmth, by a proper addition of cold water; due allowance being made for the season of the year, and the temperature of the air.

To employ only one copper in brewing is generally allowed to be bad management; because the business must, in that case, stand still in some part or the other, however well the process may be contrived. For this reason, the best and more usual method is to brew with two coppers.

The great copper, in which the water for the two first extracts receive their temperature, is built very near the mash-tub, so that the water may be readily conveyed to the ground malt. At the bottom of the copper is fixed

a cock, which being turned, lets the water run through a pipe to the real bottom of the mash-tub. This is by far the best way, because this is the most expeditious, and least liable to accidents.

When the water has been brought to a proper degree of heat in the mash-tub, the malt is run very leisurely into it, whilst another person stirs it all the time, so as to mix the whole of it uniformly with the water, and prevent any of its parts from gathering into clods. In this operation rakes should be first employed; because by their horizontal motion, less violent than that of mashing, the finest parts of the malt are well wetted, without its flour being scattered or lost in the air: but as a still more perfect penetration and mixture are necessary, oars are afterwards used, by which a thorough inhibition of the water is effected. When the mash has been sufficiently stirred, it is covered with a sprinkling of malt, and the tub itself should also be covered with sacks or other cloths to keep it warm.

After mashing, the malt and water are left untouched for an hour and a half, or two hours; and during this interval, the large copper of water is brought to a proper heat for a second mashing. The second extract is commonly mashed three quarters of an hour, and is afterwards let stand the same space of time; and the third requires half an hour, both for mashing and standing. As the first drawn wort is immediately put into the large copper, the water for the third mashing is boiled in the smaller.

Small quantities of malt brewed in large vessels lose their heat soonest, by lying thin and greatly exposed to the action of the air; and, on the contrary, a less allowance for the loss of heat is required for large quantities brewed in proportionable vessels. This is the only difference between brewing carried on in large brew-houses, and those which are made in private families. Care should be taken that the quantity of the malt be not so large as to exceed the bounds of one man's labour; nor so small as to prevent the heat being uniformly maintained. It is also of great importance never to let the malt remain with less water than will cover it.

It is the general custom in private families to brew their small-beer after their ale: but they may be assured that if they have any regard to their small-beer, it is their interest to brew it alone; for the beer thus made is incomparably better, because it then contains all the flavour of the malt, is undoubtedly more wholesome, and will keep much longer.

A correspondent of the editors of the *Museum Rusticum*, vol. IV. p. 287. has given the following useful directions for making a kind of small beer, which for cheapness, agreeableness, and perhaps wholesomeness, is greatly preferable to that made from malt. It has also this further advantage, that it may be made ready for drinking in three or four days time.

The method is this: take of water fifteen gallons, and boil one half of it in any copper or pot that may be at hand. Put the part of the water thus boiled, while in it full heat, to the cold part, contained in a barrel or cask: and then add one gallon of melasses, commonly called treacle, stirring them well together. If the vessel be new, add a little yeast; but if it has been used before for the same purpose, the yeast will be unnecessary. Keep the bung-hole open for a day or two, till the fermentation appears to be abated, and then close it up. The beer will in a day or two afterwards be fit to drink.

But to return to the management of the wort. The beer-wort must be boiled, in order to free it from particles which would render the liquor muddy and ill coloured, without adding to its strength; to extract the virtue of the hops; and to render the drink fitter for keeping.

Worts, like every other sweet vegetable juice, when once brought to ferment, are so inclined to continue their fermentation, that it is difficult to retard their progress therein, to keep their preservative qualities, and so hinder them from turning acid. Among the many methods put in practice to retard this forwardness of the worts, none promised so much success as blending with them the juice of such vegetables as are not themselves easily fermented. Hops are selected for this purpose; and experience, which has proved their wholesomeness, has also demonstrated their efficacy: for their resinous parts retard the aptness of malt liquors to ferment.

ferment. By this means they keep malt-liquors sound a longer time, and by repeated and flow frettings, give an opportunity to the particles of the liquor to be more separated and comminuted, than they would otherwise be. Fermented liquors acquire hereby a greater pungency, so that, even if they did not receive an additional strength from this ingredient, hops would be the means of improving their taste.

The aromatic parts of the hops are volatile, and a small heat disengages them from the plant. To preserve these parts in the process of brewing, the hops should be put into the copper as soon as possible, and be thoroughly heated, while the heat of the wort is at the least, and the fire under the copper has no effect there. Whoever will take the trouble of seeing this performed, will be convinced that the flavour of the hops is retained; instead of being dissipated in the air, as it always is, when the wort is first suffered to boil.

In order to extract more gradually a fragrant tincture from the hops, they should be rubbed thoroughly between the hands, and then put into a bag or fine net, so loose that the wort may be easily admitted among them, and in this state they should be placed in the receiver or under-back, so that the wort may run upon them. After this gradual soaking, during which they will communicate much of their virtue to the wort, less boiling will serve, and the beer will have their full flavour.

A correspondent of the editors of the *Museum Rusticum*, vol. III. p. 64. has made some judicious remarks on the common practice of boiling the hops in the wort. He observes that the rich, fat wort, sheaths up the pores of the hop, and, as it were, embalms the leaves, so that the beer or ale-wort can extract a very small part only of the necessary quality of the hop: but when it is put into the small beer, a fluid of a thinner nature, the pores are unsheathed; so that the latter becomes too bitter, while the former has hardly any taste of the hop. To remove these inconveniences, he proposes to soak the hops previously in a pail or two of hot water, by which means the hop will impart its good qualities impartially, and both the strong and small beer obtain a grateful bitter. And with regard to the quantity of water used in soaking the hops, allowance may be made for it in the first quantity.

When the first wort is sufficiently boiled, it is conveyed into the coolers; and if the hops are not contained in a net, it must be run through a sieve or strainer, to keep them back. If the coolers have not been perfectly cleaned from the sediment of former worts, which is very apt to insinuate itself into old or decayed wood, the wort intended to be cooled in them, will, before it is removed, contract from that sediment a degree of fermentation. This accident generally happens in a little more than twelve hours after the putting in of the wort; and therefore may be easily prevented, by not letting the wort continue so long in the coolers.

When the wort is of a proper degree of coolness, the yeast is generally put into a large bowl, and a little of the wort just warm is added to it. The yeast swims at first on the surface, but soon blends itself with the wort, and begins the fermentation. As soon as this happens, the whole is mixed with the wort in the working tun.

If the fermentation should not rise properly, a little of the finest wheat-flour sifted over the wort, so as to cover the whole surface of the liquor, will, by forming a kind of artificial head, confine the air, and soon produce the effect desired. If a greater degree of warmth should be wanted, a stone jug filled with boiling water, and put into the wort, will communicate a gentle heat to the whole, and as the liquor warms, the fermentation will come on in a gradual and proper manner.

In the course of the fermentation, it may sometimes be necessary, in order to quicken it, to beat in the yeast, or rather to stir it with a wisk, which should be perfectly clean, scalded in boiling water, and then wiped dry. It will also by this means retain some degree of warmth, which will likewise help to promote the fermentation. These measures, with an additional warmth given to the air, and warm coverings laid over the working tun, seldom fail to answer the end desired.

If the fermentation proceeds too violently, owing to the warmth of the weather, or too great quantity of yeast, the best way of checking it is, to cool the air, by giving it a more free admission, and to mix a little cold wort with the fermenting liquor. The practice of add-

ing some unctuous substance is bad, and therefore should be rejected.

Care should be taken to have the casks in good order against the time that the fermentation is completed in the tub; that is, they should be tight and clean, and perfectly free from filth or smell; for if they have either of these defects, the whole labour will be lost, because the excellency and fine flavour of the liquor will be destroyed.

The perfection of malt liquors depends not only on the proportion of the oils to the salts, and on the proportion of hops used in brewing, but also on the fermentations being carried on slowly and coolly. For this reason cool weather is best for brewing of beer intended for long keeping. If therefore the liquor be not drawn off before the fermentation has proceeded too far, some of the coarser oils will return into the liquor, and give it a disagreeable and greasy taste. On the contrary, if the fermentation has not been continued its due time, the impurities which would either have sunk down in the lees, or have been thrown up with the head, will remain in the liquor, and prevent its becoming clear and well tasted.

When the fermentation is at its height, all the dirt or foul yeast, which rises on the surface, must be carefully skimmed off.

When the fermentation begins to subside after the liquor has been drawn off into the cask, the cask should be filled up with a reserve of the same liquor taken from another vessel, but by no means with that which runs over.

When the fermentation has ceased, the cask being filled up, should be bunged close down, leaving the vent-hole open, or but slightly covered, till all motion in the liquor is subsided; and after this is over, the vent-hole should be stopped quite close. The custom of using bungs made of cork is wrong. A wooden bung should be fitted to the bung-hole as exactly as possible, and covered with a clean cloth.

BRIDLE, a contrivance made of straps or thongs of leather, and pieces of iron, in order to keep a horse in subjection and obedience.

The several parts of a bridle are, the bit or snaffle, the head-stall, or leather from the top of the head to the rings of the bit; the fillet, over the forehead and under the fore-top; the throat-band, which buckles from the head-band under the throat; the nose-bands, going through the loops at the back of the head-stall, and buckled under the cheeks; the reins or long thongs of leather that come from the rings of the bit, and being cast over the horse's head, the rider holds in his hand.

BRIDLE-Hand, is the horseman's left-hand, the right being called the spear or sword hand.

BRIM, or **BRIMME**, a word applied to a sow when she goes to the boar, which is called going to brim.

BRINING of Hay-Ricks, a practice common in America, and consists in mixing salt with the hay as they stack it.

A correspondent of the editors of the *Museum Rusticum* recommends this practice greatly, declaring that hay, which has to all appearance been spoiled by the rain, will spend as well as that made and ricked in the finest weather.

"Just before I left America, says he, I had a crop of hay, which was in a manner spoiled by rain, being almost rotted in the field; yet did this hay spend as well as if it had been got in ever so favourably.

"When my servants were making up the stack, I had it managed in the following manner; as soon as the bed of hay was laid about six inches thick, I had the whole sprinkled over with salt; then another bed of hay was laid, which was again sprinkled in the same manner; and this method was followed till all the hay was stacked.

"When the season came for cutting this hay, and giving it to my cattle, I found that, so far from refusing it, they eat it with surprising appetite, always preferring it to the sweetest hay, that had not been in this manner sprinkled with salt." *Museum Rusticum*, vol. II. p. 210.

BRITE, a word applied to hops when they are over ripe or shatter, in which case they are said to brite.

BROAD-CAST sowing. See **SOWING**.

BROAD-WHEELED Wagon. See the article **WAGON**.

BROKEN-

BROKEN-WIND, a very fatal disease to which horses are too often subject.

This disorder hitherto seems to have been little understood; but Mr. Gibson is inclined to think, that the source of it is frequently owing to injudicious, or hasty feeding of young horses for sale; by which means the growth of the lungs, and all the contents within the chest, are so increased, and, in a few years, so preternaturally enlarged, that the cavity of the chest is not capacious enough for them to expand themselves, and perform their functions.

A narrow contracted chest with large lungs may sometimes naturally be the cause of this disorder; and it has been observed, that horses rising eight years old, are as liable to this distemper, as men at a certain period of life, and, fall into asthma, consumptions, and other chronic diseases.

The reason why this disorder becomes more apparent at this age may be, that a horse comes to his full strength and maturity at this time: at six commonly finishes his growth in height; after which he lets down his belly, and spreads, and all his parts are grown to their full extent; so that the pressure on the lungs and midriff is now more increased.

But how little weight soever these reasons may have, repeated dissections have given ocular proofs of a preternatural largeness, not only of the lungs of broken-winded horses, but of their heart and its bag: and also of the membrane which divides the chest; as well as of the remarkable thinness of the diaphragm or midriff.

This disproportion has been observed to be so great, that the heart and lungs have been almost of twice their natural size; perfectly sound, and without any ulceration whatever, or any defect in the windpipe or its glands.

Hence it appears, that this enormous size of the lungs, and the space they occupy, by hindering the free action of the midriff, is the chief cause of this disorder; and as the substance of the lungs was found more fleshy than usual, they must of course have lost much of their spring and tone.

This fleshiness and size of the lungs may, in a great measure, be the cause, why the inspirations in broken-winded horses are disproportionately slow; for we may observe that they draw in their breath slowly, their flanks filling up, and rising with difficulty: but that their flanks fall suddenly, and their breath bursts forth with violence, both from the mouth and nostrils; inasmuch, that a man in the dark, by holding his hands on the horse's mouth and nose, may easily discover if he is broken-winded.

Whoever considers a broken-wind in this light, must own that it may be reckoned among the incurable distempers of horses; and that all the boasted pretensions of cure are vain and frivolous, since the utmost skill can amount to no more than now and then palliating the symptoms, and mitigating their violence.

We shall therefore lay down such methods as may properly prevent this disorder, when pursued in time; but if they should not succeed, we shall offer some remedies and rules to mitigate its force, and to make a horse as useful as possible under this malady.

It is usual before a broken-wind appears, for a horse to have a dry obstinate cough, without any visible sickness or loss of appetite; but, on the contrary, a disposition to foul feeding, eating the litter, and drinking much water.

In order then to prevent, as much as possible, this disorder, bleed him, and give him two drams of calomel, mixed up with an ounce of diapente, for two nights successively, keeping him cloathed and well littered; and feeding him with scalded bran and warm water.

The following balls are then to be taken for some time, which have been found extremely efficacious in removing obstinate coughs:

Take gum ammoniacum, galbanum, and assa. foetida, of each two ounces; squills, four ounces; cinnabar of antimony, six ounces; saffron, half an ounce: make the whole into a paste with honey; and give a ball about the size of a pullet's egg every morning.

Broken-winded horses should eat sparingly of hay, which, as well as their corn, may be wetted with chamber-lye, or fair water; as this will make them less craving after water.

The volatile salts in the urine may render it preferable to water, and may be the reason why garlick is found so very efficacious in these cases; two or three cloves given at a time in a feed, or three ounces of garlick bruised, and boiled in a quart of milk and water, and given every other morning for a fortnight, having been found very serviceable;

for by warming and stimulating the solids, and dissolving the tenacious juices, which choak up the vessels of the lungs; these complaints are greatly relieved.

Careful feeding and moderate exercise have greatly relieved broken-winded horses; and though for the first summer they have not been able to endure much labour, yet many have been found less oppressed the second, and some scarce perceptibly affected the third; and even able to bear great fatigue; and could a horse be kept constantly in the field, and taken up only when used, he might, by this management, do great service for many years.

But whoever expects to cure his horse by sending him out to graze will find himself disappointed, especially if he remain abroad after the spring graze; for on his return to the stable and dry meat, he will be more oppressed and short breathed than before, for want of the open air, and the moist food he has been accustomed to.

Horses sent to graze in order to be cured of an obstinate cough, have often returned completely broken-winded, where the pasture has been rich and succulent, so that they have had their bellies constantly full. As the ill consequence therefore is obvious, where you have not the convenience of turning out your horse for a constancy, you may foil him for a month or two with young green barley, tares, or any other young herbage.

To pursue, thick-winded horses, Barbadoes and common tar have often been given with success, to the quantity of two spoonfuls mixed with the yolk of an egg, dissolved in warm ale, and given fasting two or three times a week, especially on those days you hunt or travel.

But in order to make all these sorts of horses of any real service, the grand point is to have a particular regard to their diet, observing a just œconomy both in that and their exercise; giving them but a moderate quantity of hay, corn, or water, at a time, and moistening the former to prevent their requiring too much of the latter, and never exercising them but with moderation, as has been before observed.

The following ball may be given once a fortnight or three weeks; and as it operates very gently, and requires no confinement, except the days it is given (when warm meat and water will be necessary), it may be continued for two or three months:

Take succotrine aloes, six drams; myrrh, galbanum, and ammoniacum, of each two drams; bay-berries, half an ounce; oil of amber, a spoonful: make the whole into a ball with a sufficient quantity of syrup of blackthorn. *Bartlett's Farriery, p. 68.*

A discovery has lately been made of a cure of an asthmatic or broken-winded horse, by letting him drink freely of water in which lime has been infused; and it was first discovered by an old horse, rendered useless by his cough, being restored to health by his drinking the water that had settled in an old lime kiln. An experiment was afterwards made on a horse eighteen years old that was broken-winded; when it totally removed the complaint, and rendered him serviceable.

BROODING, the act of a hen, or other bird, sitting on a number of eggs, to keep them warm till they hatch, or produce young ones.

BROOM, the name of a plant, of which two species are natives of this country, called the common and the small broom.

The common broom is the *genista trifolia* of Mr. Ray. It rises about three feet in height, with shrubby stalks, garnished with spear-like leaves, and terminated by loose spikes of yellow flowers, succeeded by short pods, which turn black when ripe, and contain four or five kidney-shaped seeds. It flowers in June or July, and the seeds ripen in autumn. The flowers of this plant are used by the dyers to give a yellow colour; whence it is called dyer's broom, green-wood, wood-waxen, or dyer's-weed.

The small English broom, called also petty-whin, is the *genista spartium trifolium minus Anglicum* of Tournefort. It rises like the former, with a shrubby stalk, but only to the height of about two feet, sending out many slender branches, which are armed with long single spikes, and garnished with very small spear-shaped leaves, placed alternately on every side of the branches. The flowers branch out without spines, short, and have five or six yellow flowers growing on a cluster at the end. They come out in April and May, and are succeeded by short turgid pods, containing four or five small kidney-shaped seeds, which ripen in July.

This sort grows naturally upon open heaths, in many parts of England.

The twigs of broom are excellent for thatching barns, &c. being very tough, and of long duration. Ropes also, and those not bad ones, are made of the stringy fibres of this plant, of which the ancients used also to make a kind of flax.

According to Mr. Bradley's calculation, an acre of broom is worth upwards of six pounds annually, for the feeding of bees only, besides the wythes and stumps, which will pay for the rent of the land. Certain it is, that no flowers are more pleasing, or more profitable to bees, than those of broom.

But considering it as a weed, it is one of the most pernicious plants that grows upon the land; for its roots penetrate deep, and at the same time it sheds no leaves, so that it is continually sucking the moisture from the earth. The best method of destroying it, is by burning the land, then ploughing it deep, and manuring it very well with dung and ashes; or by spreading on the land chalk or marle, or manuring it with urine. If the ground be designed for pasture land, it is best to cut the broom close to the ground in May, when the sap is strong in it. By this artifice the roots are destroyed; whereas in the common way of pulling up the young plants, some strings of the roots will be left, and the least of these will grow. Foddering of cattle upon broomy land is one very good way of destroying the broom, their urine killing the roots, and their treading the land makes it less proper for the roots to extend themselves; for broom is seldom seen to grow near old paths. *Bradley's Husbandry*, vol. I. p. 181. *Mortimer's Husbandry*, vol. I. p. 308. *Mills's Husbandry*, vol. III. p. 36.

BROWN, a dusky kind of colour, inclining somewhat towards redness.

A brown horse is not reckoned altogether so beautiful as the bay or chestnut. There are also degrees of this colour, some being light, and others very dark. They have almost always black manes and tails, and often their joints are black, though not so shining as the bays, but rusty. Almost all brown horses grow gradually lighter towards their bellies and flanks, and many are light about their muzzles. The most beautiful are those which happen to be finely dappled, for the plain brown are esteemed more ordinary. Many of them are coarse, but strong and serviceable, fit for draught, for burden, or for war. *Gibson on Horses*, vol. I. p. 46.

BROWSE, branches fit for the food of goats, &c.

BRUISE, a hurt caused by the force of something blunt and heavy.

Horses and other cattle are very subject to bruises from various accidents; but as the blood is no ways affected in these cases, one general method of cure is only necessary; and that is by coolers and repellers, such as white wine vinegar, old verjuice, or compositions made with allum, vitriol, and the like, which should be applied frequently to the swelling, till the heat and inflammation is abated.

BUCK-BEAN, or *marsh trefoil*, *trifolium palustre*, a plant with large oval leaves, pointed at each end like those of a garden bean, set three together on long pedicles, which embrace the stalk to some height, and there parting, leave it naked near the top, where issues a short spike of pretty large, reddish, monopetalous flowers, each of which is cut into five segments, hairy on the inside, and followed by an oval seed-vessel. It is perennial, grows wild in marshy places, and flowers in May.

Sheep, when sound and in health, always avoid eating buck-bean; but when the symptoms of the rot begin to attack them, they search for it by instinct, and devour it greedily. Where such sheep are pastured, no buck-bean is to be found, for in a week or two they devour it all. Might it not be prudent, therefore, in husbandmen, who graze large flocks, to cultivate an acre of this plant in some morassy ground, which otherwise would not yield them two shillings the acre? Some might be cut up green, for unsound sheep, and given them with lucern, as occasion requires; and some might be made into hay, and mixed with their fodder. I cannot remember that this advice has been given by any husbandry writer. *Essays in Husbandry*, Essay II. p. 137.

BUCK-WHEAT, the name of a plant generally considered as a species of corn, though not such in fact; nor does it grow like any of the esculent grains. Its leaf, from being roundish at first, takes nearly the shape of that of ivy, but longer pointed, and much softer. Its stalk is round,

hollow, and weak, sometimes reddish, but most commonly green, and growing to the height of about two feet and a half. Lateral branches, which shoot out almost at every joint, are terminated by purplish flowers, which are succeeded by small triangular seeds, black on the outside, and white within.

Buck-wheat will thrive in any soil, not excepting even barren sands, as they are commonly termed; but grows largest in dry ground which have been well ploughed. When raised for its grain, a bushel of seed is sufficient for an acre of land, which will frequently yield fifty or sixty bushels: but when it is intended for green fodder, which is the use most commonly made of it here, some people sow three or four bushels on an acre, in order to have a thick crop. The usual time of sowing it is about the beginning of May; but if it be sowed somewhat earlier, and a warm season ensues, it will bear cutting twice in the summer. It comes up soon, and ripens generally, according to M. du Hamel, in one hundred days after sowing, so that buck-wheat sown in June is reaped in September.

When mowed, it must be left in the field several days, that its stalk may dry before it is housed. There is little danger of the seeds falling out, nor is it much injured by wet. These seeds are excellent food for pigeons, poultry, hogs, rabbits, &c. and are found to make horses thrive when given among their oats; but for these they should be first cracked in a mill; being apt, otherwise, to pass through them whole. The flour of buck-wheat is very white, and makes a good sort of pancake, when mixed with a little wheat-flour. The poor in some countries make even bread of this mixture; but it is black, bitter, windy, and not nourishing. Its straw, or haum, is also given dry to cattle: but the best way is to feed it whilst green, particularly just before it blossoms. Milch cows fed with it will yield an extraordinary quantity of milk, remarkably good for making butter and cheese: and another advantage attending this pasture is, that it will continue green in the driest time of summer, when other grasses are burnt up. It is an excellent dressing for land, where ploughed in without being mowed.

The ingenious author of the *Essays in Husbandry* tells us, that in certain lands of Brabant, called Rempen, the husbandmen raise buck-wheat in small fields near home, and place round them, under the hedges, a great number of bee-hives, from whence they draw considerable profit; for no plant affords these insects a better supply of materials for making honey. *Essay I. p. 110. Mortimer's Husbandry*, vol. I. p. 136. *Du Hamel's Elements of Agriculture*, vol. I. p. 91. *Maisons Rustiques*, tom. I. p. 624.

Mr. Marshall, in his *Rural Economy of Norfolk*, says "Buck is an object of the Norfolk culture, in a two-fold light. It is propagated as grain, and as manure; and it will be proper to view it in these two lights. However, the main intention of its propagation, whether as a crop, or as a melioration of the soil, being the same, namely, the cleansing of foul land, it will be convenient to keep the two objects in nearly the same point of view.

With respect to species, there is only one; this grain having not yet, I believe, run into any varieties sufficiently striking to have distinguishing names appropriated to them.

It is sown almost indiscriminately on all species of soils; except that light poor land has the preference: indeed it is to this species of soil that buck seems most especially adapted.

It likewise succeeds every species of crop; the state of the soil, as to foulness and poverty, being generally more attended to than either the nature of the soil or the crop it bore last.

The soil-process depends upon the state of the soil, and the intention, jointly: if the soil be tolerably clean, and the buck be intended to be plowed under as a manure, it is sown on one plowing: but, in general, the ground is broken, as for barley or peas, to forward the fallow, and secure a crop.

The seed-process is the same for both intentions; excepting that, for a crop, the seed is sown first; namely, immediately after barley-seed: and that intended to be plowed under, is sown as soon afterwards as the ground is in a state fit to receive the seed. It is universally sown above-furrow. The quantity of seed six pecks to two bushels an acre.

No vegetating process takes place: the growth of buck is so rapid as to outstrip and smother almost every species of weeds; an excellency peculiar to this crop.

The method of plowing buck under, and the after management-

nagement of buck-fallows, is nearly as for wheat. The harvest process is like that of barley, as is that of its farmery and management; except that the straw being fit for litter only, and the grain being wanted for the fattening of pigs, in autumn, and the beginning of winter, it is frequently thrashed out presently after harvest, before the live stock are taken into the yards."

Mr. Young, in his *Annals of Agriculture*, vol. I. in a letter from a correspondent; "Recommends to all persons who have horses to feed, to try the efficacy of buck-wheat, mixed with bran, chaff, or grains, either in the whole or broke in a mill: it had been proved to recover a favourite old coach-horse (he is fondest of it unground) when all other sort of food failed. It is presumed, as the grass flushes cows with milk, that the flour or meal, mixed with grains, will have the same good effect, and enrich the milk. It is surely worth trying. A bushel of it, which goes farther than two bushels of oats, even with beans, mixed with at least four times as much bran, will be full feed for any horse a week, and much less hay will do. Four bushels of the meal put up at two cwt. will fatten a hog of sixteen or twenty stone in three weeks; then give him three bushels (of Indian corn, if you can get it) of hog-pease, broken in a mill, dry, with plenty of water (for as the pease are small, so they swallow and part with them whole), and you will find most delicious meat; but it must be understood, the hog so fattened, must be in pretty good order when put up; but be assured, that eight bushels of buck-wheat meal will go as far as twelve bushels of barley-meal. I write from experience.

In regard to poultry (pigeons eat it whole with great avidity) it is a vulgar error, "That it renders the hens so fat they will not lay." If there is the least foundation for such a surmise, it is because they over-feed them.

The reluctance shewn to the cultivation here in England of this valuable grain is rather wonderful, especially considering the number of treatises on the improvements of agriculture. Yet it seems a tempting inducement, if the farmer will but reflect, "That as one bushel will be very sufficient to sow an acre, which bushel only costs four shillings and three-pence, it is cheaper than a single load of dung." And the advantages produced therefrom are three-fold, viz.

- 1st. To plough it in, which mends the land.
- 2d. If a dry summer, it is fodder for the cattle.
- 3d. If you let it stand for a crop, it may produce an equal quantity with oats, and will always sell for more money; and, farther, think that an acre of oats requires four, even to five, bushels, to sow it; whereas one bushel of buck-wheat will sow an acre. This plant ameliorates the soil so much that the farmer may have any crop after it, especially wheat, in which system it is commonly cultivated about Norwich. Now it must surely be apparent at the first blush, what a prodigious advantage it would be for the farmer to feed his teams by a crop which improves his ground and prepares for wheat, rather than by another which exhausts it, and throws him so much the further from the golden grain."

BUD, that part of the seed which first begins to sprout, or rather the leaves which first appear.

BUD also signifies the sprout from whence the branch arises. These buds in some measure resemble seeds, as under a number of scaly coverings the rudiments of the young branch are seen: but neither the lobes nor the young root are met with; because this tender stem is connected with a tree, which supplies it with the necessary food.

BUD is likewise used in some counties in England for a weaned calf of the first year; because the horns are then in the bud.

BUGLE, *Middle compound, Sicklewort, or Herb Carpenter*, the name of a low weed, with two kinds of stalks; round creeping ones, which strike root at the joint; and upright square ones, hairy on two of the opposite sides, alternately, from joint to joint, bearing loose spikes of blue labiated flowers, of which the upper lip is wanting: the leaves are somewhat oval, soft, slightly cut about the edges, and set in pairs at the joints. It is a perennial weed, infesting moist meadows and pasture-grounds, and flowers in May.

BUGLOSS, or *Viper's Bugloss*, the name of a plant whose stalks are rough, round, solid, erect, undivided, and marked with black spots: the leaves are very rough, long, narrowing to a point, and placed without any certain order. The flowers are large and spacious, of a beautiful blue co-

lour, and grow in long bending spikes. They consist of one petal divided into five roundish segments, of different sizes, and resemble a horn in their figure, expanding by degrees, from a narrow beginning. The flower cup consists of five narrow segments, and contains four rough seeds.

Bees are very fond of the viper's bugloss, and there is reason to think that this plant, assisted by the culture of a skilful gardener, may receive, perhaps, as many improvements as the auricula did. Its branches will rise to the height of three feet, and no vegetable would better adorn flower-pots in large chimnies: for if the water be changed, it continues blowing near a fortnight after cutting. Its ultramarine blue-colour, is the finest that can be seen, and the stalks are garnished with flowers from top to bottom; dyers might, perhaps, extract an useful tincture from the roots. This plant grows wild in hard brashy soils. *Essays in Husbandry. Essay I. p. 110.*

BULL, the males of the ox kind. See the article OX, and CATTLE.

The bull, kept for propagating the species, should have a quick countenance, his forehead broad and curled, his eyes black and large, his horns large, short, and black, his neck fleshy, his belly long and large, his hair smooth like velvet, his breast big, his back straight and flat, his buttocks square, his thighs round, his legs straight, and his joints short; this sort of bull is the best for breed, and makes the best ox for draught. *Mortimer's Husbandry, vol. I. p. 226.*

The bull chiefly serves for propagation; and though he may be subject to the yoke, yet there is no being certain of his working quietly; and the use he may make of his prodigious strength, is constantly to be guarded against. This creature is naturally untractable, stubborn, and fierce; and in the bulling season, absolutely uncontrollable, and often furious; but, by castration, the source of these turbulent impulses is destroyed, without the least diminution of his strength. He also grows larger, more heavy and unwieldy, and becomes more adapted to the labour for which he is designed. This operation also renders him more tractable, patient, docile, and less troublesome to others. A herd of bulls could not be either tamed or managed by human skill. *Buffon's Histoire Naturelle, tom. IV.*

BULLEN, hemp stalks stripped from the bark.

BULLOCK. See CATTLE.

BULLOCK-STALLS, or SHEDS. Mr. Marshall, in his *Rural Economy of Norfolk*, gives the description of a bullock-stall as follows: "It consists of a center building, thirty-six feet long, nineteen feet wide, and about eleven feet high to the eaves; with a pair of wide folding-doors at each end; and with a lean-to on each side, the whole length of the building, and eleven feet wide.

The center building is the turnep-house; the lean-to's, sheds for the bullocks; which stand with their heads toward, or rather in, the turnep-house; from which they are parted by a range of mangers only; having the full freedom of breathing in its spacious area. By opening the doors at each end, a sufficient degree of air and coolness may be given in the close stweather; while, behind, the eaves of the sheds are brought down to within five feet of the ground, and are boarded with rough boards (excepting an opening at each end for the bullocks to creep in at) to prevent too great a coldness in severe weather; thus preserving a due temperature.

This shed holds twenty bullocks, ten on each side, fastened by the neck, with chains, swivels and rings, playing freely upon posts, seven feet high. At each corner of the turnep-house is a triangular bin for the topped-and-tailed turneps.

In autumn, the entire building is sometimes used as a temporary barn, for buck, peas, &c. and in summer, the center part is an excellent waggon-shed: had the doors been made a foot and a half higher, it would have been an admirable refuge for loads of corn or hay in a showery harvest.

The main building is covered with reed, the lean-to's with tiles."

Mr. Marshall, in his *Rural Economy of Gloucestershire*, says; "What characterizes the bullock-sheds in that vale, and distinguishes them from those of every other, he observed, is the circumstance of each bullock having a house and a yard to himself; in which he goes loose; occupying them by turns, as appetite or amusement directs him: having a manger and a drinking trough to go to at pleasure. He, of course, eats when he is hungry, and drinks when he is thirsty. He is also at liberty to rub, or to lick himself: as well as to keep his body in a degree of temperature,

as to heat and cold. Theory could not readily suggest more rational principles.

The construction of these stalls varies in the minutiae. The water trough, for instance, is sometimes placed by the manger, in the hovel or shed: sometimes in the open pen. Other less noticeable variations may be seen in different buildings.

The plan and dimensions, which, at present, seem to stand highest in esteem; and on which several erections of this nature have been made within the last fifteen or twenty years; are the following.

The building fifteen to fifteen feet and a half wide within, and of a length proportioned to the number of stalls required. The height of the plates six feet to six feet four inches; supported on the side to the north or east by close walling; on that to the south or west by posts, set on stone pedestals. The gables walling. The covering plain tiles, on a single pitch-roof.

Against the back wall is a gangway, three and a half to four feet wide, formed by a length of mangers, three feet to three and a half feet wide, from out to out, at the top; narrowing to about fifteen inches within, at the bottom. The perpendicular depth fourteen or fifteen inches; the height of the top rail from the ground, about two feet nine inches. The materials two-inch plank; stayed and supported by posts and cross pieces; and stiffened by strong top-rails.

The dimensions of the area of the covered stalls, about eight feet three inches square; of the open pens, the same.

The partitions between the stalls are of broad rails, passing from the outer pillars to similar posts, rising on the inner or stall side of the manger; and steadied at the top by slender beams, reaching across the building; each stall, or each partition, having a beam and a pair of principals.

The partitions of the pens are gates, reaching from the pillars to the boundary wall; and likewise from pillar to pillar. When they are fixed in that situation, each bullock has his stall and his little yard. When in this each is shut up in his stall, the yards forming a lane, or driftway, for taking in, or turning out any individual.

The boundary wall of the pens is about four feet high, coped with blocks of copper-dross. On the outer side of it is a receptacle for manure: on the inner a range of water troughs, with a channel of communication for the convenience of filling them. The materials of the troughs, stone; of the channel, gutter-bricks, covered with slabs. These stone troughs, which are about fourteen inches by two feet six inches within, have a convenience in their construction, which is entitled to notice: instead of the sides and the ends being all of them pecked down to an angle, square with the bottom, one of the ends is left bevelling, sloping, making a very obtuse angle with the bottom. This simple variation renders them easy to be cleaned; either with the shovel, or the broom.

The floor is paved with hard-burnt bricks, laid edge-way in mortar; being formed with a steep descent from the wall to a channel, from three to four feet from it; and with a gentle fall from the manger to the same channel; which becomes the general drain for rain-water and urine.

At one end of the pens is a pump (where a natural rill cannot be had; for supplying the troughs of water; and, at the other, a stack of stubble for litter; which is used in the stall only; the yard being left unlitteed.

At one end of the building is a cake-house, at the other, the rick-yard; with a door at each end of the gangway to receive the hay and the cake.

In one or more instances, Mr. Marshall had seen a double range of stalls on this plan; the area between them being the common receptacle for the dung. When a number of stalls, as twenty or thirty, are required, this arrangement brings them within a convenient compass; and the two ranges, with a proper aspect, become shelter to each other.

Beside these loose stalls, there are others, built nearly on the same plan, but without gates, and on a somewhat smaller scale, in which the cattle are fastened to the manger, or the partition posts, with a long chain, which gives them liberty to rub and lick themselves, and move about in their stalls. In this case, a water-trough is generally placed at the end of every second partition, level with the manger, with a general pipe of communication to fill them; each trough supplying two bullocks. This plan lessens the expence in some degree, and prevents the bullocks from fouling their mangers.

There are individuals in the district, who have fifty, or more, of one or the other of these stalls, on their respective premises.

In the Cotswold Hills, Mr. Marshall says, each bullock has a trough; a small one for corn: a large one for hay; with a water trough, which runs the whole length of the shed, and is covered by a board; each bullock having a hole to drink at." See STALL-FEEDING.

BULLS-FOOT, the same with colts-foot. See COLTS-FOOT.

BULLWEED, *Great Knapweed*, or *Matfellow*, the name of a perennial weed common among corn; it rises to about two feet high; the stalks are round, streaked and hoary: the bottom leaves are oblong and undivided, but those which grow on the stalk are cut and divided. The flowers resemble those of the blue-bottle in shape, but are of a red colour. The seed is small, oblong, reddish, and hairy in the upper part.

BUNS, the stalks of hemp after the bark is taken off.

BURN-BAKING, or *Burn-beating*, often called *Devonshire*, or *Devonshire*, for its being long practised in that county, a method of cutting up the turf, and after drying and burning it, the ashes are spread over the surface by way of manure.

This method of improving land is very ancient. Virgil mentions it; and it has been practised time out of mind in Cornwall and Devonshire. The marquis of Tourbilly has founded his famous treatise *Sur les Défrichemens*, published in 1761, principally on the art of burn-baking. We shall here give the substance of what the marquis has delivered on that interesting subject.

When it is intended to break up any piece of waste-ground, the nature of it should be first considered, and may, in a great measure, be known from its natural produce, which is generally heath, rushes, fern, broom, furze, brambles, &c. intermixed with grass: for, from the height, thickness, and vigour of this wild growth, a proper judgment may be formed with regard to the degree of the goodness of the soil, and what may reasonably be expected from it.

When such ground is to be broken up, it will be right to begin in the winter in order to get rid of the three principal obstacles, namely, water, stones, and such large roots as the paring mattock, or beating axe, as it is called in the west of England, may not be strong enough to cut. Afterwards, about the middle of March, the paring of this ground should be begun, by a number of labourers proportioned to the extent of the land intended to be pared.

Every one of these labourers must be provided with a paring-mattock, or beating-axe, the form of which is represented on Plate II. fig. 1. Towards the edge, where it is sharpened like an addice, it should be made of well tempered steel, and about nine inches wide. From thence the iron part, which should be six inches in length, lessens in breadth towards the handle, as in fig. 2. where it is reduced to three inches. All the upper part must be made of the best iron, and should be formed somewhat hollow, with a little bending inward. It should be strongest in the middle, and of a thickness proportioned to its size, as well as to the work for which it is intended. The hole to receive the handle should be two inches in diameter, and the handle should be of wood, about three feet long, or a few inches more or less, according to the height of the man who uses it. This instrument, exclusive of the handle, should weigh from ten to twelve pounds, according to the strength of the labourer; as less weight would not be sufficient for the purpose.

The stoutest and most intelligent labourer must be then singled out to lead the rest; for they cannot work in a row as when they dig. This leader standing in a proper posture to manage his beating-axe, must give two strokes with it, cutting into the soil, to the right, two more strokes to the left; and afterwards a fourth straight before him; by which means he will immediately raise a turf about a foot and a half long, a foot broad, and four inches thick of earth. This turf resting upon the axe as it was cut, is then, with one motion, to be placed on the labourer's right-hand, in its natural position, with the mould side downwards. (See Plate II. fig. 3. where *a, a, a*, are three tusks as cut from the soil.) All the wild growth upon his land, will, if not very large, come off with the turfs thus cut; and the more there is of it, the better it will be. The turf must absolutely be cut with a depth of at least four inches of soil; for if the ground be pared to a less thickness, the work will be badly

KILN

badly done; because the beating-axe will not have gone under the netted roots of all the rubbish growing on the surface, which it is indispensably necessary to destroy: otherwise these roots will make fresh shoots, injure the corn, and in time choak it entirely, as has happened to me in the beginning of my undertakings.

The workmen, especially if they undertake the work by the acre, would be glad to take this turf off as thin as possible; because that would save them a great deal of time and labour. But I have experienced to my cost the imprudence of making such bargains. They must therefore be well watched; for otherwise, besides the inconvenience of not effectually destroying the wild, such thin turf would not yield a sufficient quantity of ashes for manuring the land. The business will indeed go on slower, but practice will soon render the workmen more expert.

Their leader having cut a turf, and placed it on his right-hand side, must then advance a small step, and take off another of the same size and thickness, which he must also place on the same side, in a line with the former, on the further end of which the nearest end of this should rest, so as to incline a little. He is then to proceed straight on, laying all the turfs in the same manner. As soon as he has taken up the two first turfs, the second labourer, standing on his left hand side, is to take up his line of turfs in the same manner, and place them on his right, in the void space cleared by the leader. As these advance, each of the other labourers, successively one after the other, must put himself on the left of the proceeding, at the same distance, and do the same work, following each other like reapers. Thus, if the first began at B (Plate II. fig. 10.) he lays his turfs along the line which terminates the plate; and when he has cut two turfs, the second begins at C, and lays his turfs in the space BA, cleared by the first. The third follows the second in the same manner, clearing the space FE, and laying his turfs in the space CD, cleared by the second. The fourth clears the space GH, and the fifth JK, and so on. The same must also be understood of fig. 8, and 9, which therefore require no further explanation.

When the labourers come to the end of the ground, which will likewise be in progressive order, the leader must return to the side where he first began, and resume his work close to the space already pared, the others are to follow in their regular turns, and repeat the same operation as before; for this work must always be performed in the same direction, and not backwards and forwards. Such should be the method till the whole ground is pared.

If, as it sometimes happens, there be reason to apprehend that the fods will not dry fast enough when only laid a little slanting, with the end of one just resting upon the extremity of another; they may in this case be piled, as fast as they are cut, in little heaps of three, four, or five together, according to their thickness, and the quantity of combustible or vegetable matter contained in them. The air passing between these fods, which are always laid with the heath or turfy side uppermost, penetrates and soon dries them, especially if the weather be sultry: but at the same time it would be wrong to wait till they are quite dry, because they would then burn too much, and too fast; in which case their ashes are neither so good, nor in so great quantity, as those of turf more slowly burnt. A just medium, which practice will easily teach, is to be observed in this respect.

Sometimes these turfs are set upon their ends, two and two meeting at the top, and being further asunder at the bottom, like the roof of a house, with their heathy sides outwards, as represented at *b, b, b*, (Plate II. fig. 4.) but this method, which lengthens the work, and therefore renders it more expensive, is fittest for the turfs of bogs or marshes, when cut too wet.

With respect to the roots, which I said must be got rid of before any land can be properly broken up, I meant only such large roots as the beating-axe cannot cut through, though sharpened with a whet-stone from time to time, when its edge is either turned or blunted. For with regard to the roots of smaller size, such as those of the dwarf furze, the common heath and young fern, small holly, young plants of thorns and junipers, brambles, broom, and other wild productions, which have not attained too great strength, will, without much difficulty, be cut and pared off with the turf.

But the strong roots of shrubs, bushes, &c. which the beating-axe cannot sever, must remain in the ground, though that will not hinder our taking off the turf between them to a proper thickness. The fods thus cut will indeed be often

very irregular in length and breadth; but they are the better for burning, as they contain a greater proportion of vegetable matter.

It has been already observed, that these turfs should be laid in little heaps as they are cut; these should be placed in the intermediate spaces, where the ground has been placed between the roots yet remaining in the earth. These roots should be grubbed up with a spade, pickaxe, &c. without disordering the little piles of fods. It will be sufficient if this work be finished before the time of sowing. See the article GRUBBING.

Some grub up these roots before they burn the turf, and others after, as best suits their convenience: but in the latter case they should certainly be taken up in those places where the furnaces are to be made, because it is of great importance not to stir the heaps of ashes produced by them, till the very instant of sowing. The holes also made by pulling up large roots, shrubs, &c. should be filled up so as to render the surface even. In countries where wood is scarce, these roots, stumps, &c. are carried away, and dried for fuel, especially for the kitchen; by which means they frequently repay at least the expence of grubbing them up. But in places where wood is of so little value as to render these not worth the carrying off, the best way is to burn them with the turf, the ashes of which they will both increase and improve.

The thicker any land is covered with these wild productions, the better it will prove. If it costs more than another parcel of ground to break up, and bring it into order, it will, in return, make ample amends, by producing greater crops.

When the season is not too wet, the turfs will generally dry sufficiently in about three weeks, even without being turned; but in rainy years they require a longer time, and must be turned again and again, to prevent their striking out new roots and shoots, which would hinder them from burning, as I have seen happen. Hence it appears, that this method of clearing and breaking up ground requires a longer time, and is attended with more labour and difficulty in rainy than in dry seasons. But as the turfs may be turned by women and children, the additional expence will not be very considerable.

About Midsummer, or a few days before, when the turfs are sufficiently dry, a number of women and children should be employed, in fine clear weather, to gather them all up; some with iron forks, others with their hands, and pile them up from space to space, in round heaps about ten feet high, and of the same width at bottom, almost in the shape of charcoal furnaces. The heathy side of the turf must be placed downwards, and the earthy side upwards. A small hollow should be left in the inside, in order to form a kind of chimney, the opening of which should face the wind. *a b* Plate II. fig. 5. represents a furnace of this kind partly built, where *f* is the door, or opening into the chimney of the furnace. Fig. 6. is a furnace completed, where *e* is the top of the chimney, and *d* the door. Fig. 7. represents a great number of these furnaces on fire.

It has been already observed, that this work must not be set about in rainy weather; because if the heaps of turf should unfortunately be so much wet as to imbibe the water, they would not burn, but must be pulled down and spread anew, to dry as before. They might also, in this case, require very frequent turnings, as has happened to me; which would retard the operation, and increase the expence: besides which, it might not even be possible, by frequent turnings, to dry them sufficiently, before autumn, if the rains were frequent, which must occasion a very considerable loss.

However, this last accident, though possible is very rare. It never befel me; and by inquiring of those to whom it has happened, I found that it was, in a great measure, owing to their own negligence. The best method to avoid these inconveniences is, to embrace the advantage of the first fine weather, and if it appears at all uncertain, to set more hands to work, without aiming at an ill-timed saving: for it is upon the due piling up and burning of the turfs, after being properly cut and dried, that the whole success of this important branch of husbandry chiefly depends. It cannot therefore be done too speedily. When rain is apprehended, every other business should be left for this, and all hands, men, women, and children, should be instantly employed, to dispatch it as soon as possible. Nothing requires greater diligence. The heaps should be set on fire the moment they are finished, or at least, though the weather should

seem settled, before the husbandman retires in the evening. Children may do this, by putting a little lighted straw or heath, with an iron fork, into the chimnies of the furnaces. The dry heath, grass, and roots will catch instantly, and in a few moments the fire will be so violent, as scarcely to be approached. It may then be left, after taking proper precautions to prevent its extending further than it ought: especially if it be near any wood, hedge, or heath, where it might otherwise do great mischief.

The misfortunes occasioned by fire have been so numerous and dreadful, that too much care cannot be taken to guard against them. If the situation of the land, which is to be burned be such as gives the least room to fear any danger of this kind, the furnaces should only be lighted in calm weather; lest the wind should spread the flames to neighbouring grounds, where it might be impossible to stop them till they had done irreparable damage.

If it be surrounded on all sides with woods, heath, or other vegetables easily set on fire, a row of furnaces should, in this case, be made around the land to be burned, at the distance of twenty-five, or thirty feet from the neighbouring grounds, and at least ten feet from the other furnaces, which are afterwards to be built farther within this inclosure. Care should then be taken to observe from which side the wind comes, and fire should be set to those furnaces that are situated farthest from the wind, or nearest to that side on which the wind blows. A number of men should watch these furnaces while they burn, and shovel up earth upon them, if they are so full of heath or combustible matter as to occasion too violent a flame.

The throwing on of this earth will deaden the flames, and concentrate the fire; by which means the furnaces will be consumed by slow degrees, without hurting either the outward borders of the pared land, or its inner parts, where this fire might do mischief two ways; first by spreading to, and burning the yet unpiled turfs, the ashes of which would soon lose their virtue, if scattered upon the soil in this loose manner; and secondly, by catching the other furnaces, in case they should be already made; by which means the fire would soon become so great, that it would not be longer possible to stop its progress, or prevent its extending to the neighbouring grounds.

When the first row of furnaces is thus consumed, the next row may be burnt in the same manner, and so on till the whole is finished.

The morning is doubtless the most proper time for lighting all these furnaces, because the people employed in business have then the whole day before them, to watch the fire and prevent accidents, which it might be difficult to remedy in the night, particularly during the first violence of the flames. A number of proper persons proportioned to the extent of the ground, should remain upon the spot all night, as well to attend the burning of the turf, as to hinder wicked wretches from setting fire to other places, of which there have been too many instances.

By not neglecting any of these precautions, though all of them are not necessary where the fire cannot spread to adjacent grounds, every inconvenience may certainly be avoided.

If it should be found necessary to light the furnaces in the evening, though as I have just observed, the morning is a much fitter time for it, they must be suffered to continue burning till the next day, when the violence of the fire will be abated. A few men, or even women and children, should be then sent in among the heaps, with iron forks, to give them a little stirring, and lay upon them the turf which may have fallen down. These furnaces will still continue burning for some days, during which the turfs will be slowly consumed or calcined. If any of them should be situated on wet spots, where they will not burn, these women and children must mend them, and add fresh fuel, such as dry heath, stubble, or even a little dry wood, with some of the burning turfs from the adjacent furnaces. As soon as the fire is extinguished in all the heaps, which will be then reduced to heaps of ashes, finer or coarser in proportion to the goodness of the soil, the women and children must shovel them up into little round heaps, lest they should lose their fertilizing quality, if left in the manner they fell in their burning: for all our treasures consist in the salts contained in these little heaps, and the volatile parts of those salts, which are much the best, would soon fly off, if exposed to the air. The dews at night, and the first rain which falls upon these heaps of ashes, form on their surface a crust, which hinders their being blown away by the wind, renders them impenetrable to the action of the air, and keeps in all their vir-

tue: the sooner therefore rain falls after this operation, the better. Nor would it be any injury if it should rain as soon as the furnaces are thoroughly lighted, unless it should be very violent indeed, and of long continuance, which rarely happens at this season.

When the ashes are thus laid up in little heaps, nothing more remains to be done to this ground till the time of sowing; care indeed must be taken, that neither men nor cattle approach them and break their crust. The land will from hence be freed from seeds of weeds, and other wild productions, as well as from all worms, insects, reptiles, and venomous creatures; the action of the fire of the furnaces being so strong, that it heats not only the earth, beneath them, to the depth of several inches, but likewise all the intermediate soil.

A fortnight after the usual seed-time of the country, for wheat and rye, will be early enough to sow this burnt ground. When that is to be done, a number of women and children should be sent into the field, on a still, calm day, with wooden shovels, to spread the ashes equally over all the ground, excepting the spots where the furnaces were; for these are so thoroughly burnt, that they want no farther manure, and are always observed to produce the finest corn. Some of these women and children should also carry iron forks, to break and spread such turfs as may not have been thoroughly consumed; for these having been baked or calcined by the action of the fire, will be very beneficial to the land.

Immediately after the ashes are spread, the corn, whether wheat or rye, should be sown over those ashes by a skilful sower, in not more than about half the quantity generally used for a similar extent of other ground. The ploughman should follow the sower, with his team, either of horses or oxen, yoked, to a strong plough, having two fins to the share. *See the article PLOUGH.* He should not, however, cut too deep this first year, but make only shallow furrows, going and returning, to cover the seed. Women and children, with hoes and iron forks, should then be employed to break carefully all the clods, together with every remaining bit of turf; and finally to close the tops of the ridges, which the plough cannot do with the necessary exactness in this ploughing. If several ploughs work at the same time, as is generally the case with many, the number of women and children must be increased in proportion, and there must be a sower before each plough.

It is very difficult to sow these lands with half the quantity of seed generally used in other places. The most dexterous are apt to mistake, and I have experienced the bad effect of employing only one sower for several ploughs. A man who goes before each of them will sow much more equally: nor need he even lose any of his time, because when he is not employed in sowing, he may help the women and children to break the clods. The ploughman should always proceed slowly and cautiously in this first tillage, especially if the ground seems never to have been ploughed before. If his plough should chance to be stopped by any stones or roots, which may have escaped the endeavours used to discover them by means of the borer (which should be always had recourse to as soon as the surface of the ground is cleared) the other men within call, or even the women and children, must immediately take them up with crows, and pick-axes, and carry them out of the field.

Care must also be taken not to spread the ashes out of the heaps over more ground than can be sown in the same day and the next morning, that they may not be unnecessarily exposed to the hazard of losing their efficacy: but if it should begin to rain, or the succeeding day be a Sunday, no more ashes should be spread than can be sowed and ploughed immediately. These two circumstances excepted, it will be right to spread over night what is to be ploughed in next morning; for I have experienced, that the little nipping frosts in this advanced season, will often be strong enough to freeze the ashes and bits of turf not thoroughly consumed, so as to render them unfit for spreading, till the sun has thawed them; by which means a morning's work might, without this precaution, be lost.

When the seed is sown and covered, drains should be cut with the same plough, either directly across the furrows, or in an oblique direction to them, according as the declivity of the ground may require, in such manner that they may empty themselves into the main surrounding ditches, to carry off the water, especially in the winter. Some of the men employed in breaking the clods

clods will easily deepen these drains, to whatever degree you may think proper, with an instrument shaped like a hoe, with a strong flat iron spike, about fifteen or sixteen inches long, on each side of it. This instrument is very useful, and even necessary, upon several occasions; nor is there any better for stirring the ground. It will likewise serve to complete the breaking up of such parts of the spots where the furnaces stood, as may not have been sufficiently cut by the plough; and to finish the imperfect ends of the furrows, next the head lands, where the plough could not reach, and where the grain would be otherwise exposed to the air and birds.

Though the spirit and warmth of the salts contained in the ashes, will soon render this corn more forward than any other; yet as there will not be among it either grass, weeds, or wild productions of any kind, the seeds of all these having been destroyed by the action of the fire, it will appear thin during part of the winter: but on the approach of spring, it will shoot up, spread, and tiller, so as often to become too thick at last. It always ripens about a fortnight sooner than any other corn in the country; and the finest, as already observed, is constantly found on the spots where the furnaces were erected; the effect of the fire having been greater, and penetrated deeper in those than in any other places.

As all our riches, as before observed, consist in the ashes, the more there is of them, the more the ground thus broken up will be fertilized. But all kinds of soil do not afford an equal quantity of ashes when burnt; for though the burning be performed with ever so much care, repeated experience for some time past has taught me, that only some of the earth and stones, according to their quality, are reduced into lime, or calcined, by the operation of the fire, and that other parts of them will run into glass. The soils that calcine most are undoubtedly best, and yield the largest produce of ashes; while those, on the contrary, which burn to a glassy substance, are the worst, and give the fewest ashes. Of this kind is sand; and indeed, we may judge with certainty of any soil intended to be improved by burn-baking, by previously making trials on different parts of it. If the owner cannot go thither himself, he may order some of the turfs cut with a depth of four or five inches of earth, to be brought to him, in order to their being dried and burnt. He may also have, in the same manner, in bags of paper, properly numbered, samples of the soil, or of the stones underneath, at every six inches for the surface, to the depth of eight or ten feet. These samples may be easily procured by means of the borer, already described under that article.

If the person who makes these trials be not provided with a borer, holes may be dug. They will not cost much, and he will be thereby enabled to judge what grain, trees, or other productions, each soil is best adapted to. I have often practised this method with success, for improvements which lay at such a distance that I could not immediately inspect them myself: but as the judging of lands in this manner, without actually inspecting them requires great attention and long practice, the surest method therefore is to examine them on the spot, and there make the necessary experiments. The furnaces which are the most burnt, or those which burn the fastest, are not the best; for the ashes are there too much calcined, and their quantity reduced.

I have often seen much finer corn grow in places where the uppermost turfs of the heaps, which had burnt slowly, were only calcined, and remained so nearly entire, that it was necessary to break them before the ground could be sowed, than in those places where the furnaces, after being entirely burnt, were totally converted into ashes. In general, those heaps which produce white ashes, after they are burnt, are the least valuable, and commonly yield the smallest quantity. This denotes a greater degree of vitrification than of calcination. In proportion as the ashes are yellowish, brown, or blackish, which last indicates the greater perfection, they are better in quality, and generally more in quantity. According as these different colours appear, the calcination exceeds the vitrification. I have dwelt the longer upon these different operations of the fire in the burning of land, because they are of great importance to those who break up ground in this manner, and no writers have hitherto given a sufficient distinct account of them, for want of having had the necessary experience.

I must farther observe, that no land ought to be pared again, too soon after it has been burnt; because its turf being destitute of a proper covering, would not take fire well, as I have experienced. It will be necessary to

wait till the heath or broom has shot up sufficiently, which seldom happens in less than about two years. The dangerous practice of some country people, who frequently set fire to their heaths in the spring, under pretence of bringing up grass for cattle, is so contrary to the right method of improving land, by burn-baking, that it always retards, and sometimes absolutely prevents the execution of this far more beneficial method; especially if those burnings have been too often repeated.

In countries where it is not the custom to plough in ridges, but either in broad lands, or quite flat, in order to sow afterwards with the harrow, I think it would, however, be right, to sow the ground thus broken up, at least the first year, under furrow, with the two-finned plough already mentioned; after which usual method of the country may be followed, if it be found the most proper. I advise this as the best practice, and am satisfied that none will have cause to repent the trial. It will save the greater part of the expence of ploughing; and the ashes being less exposed to the action of the air, will the more strongly retain their fertilising power. But if, notwithstanding these reasons, the common practice of the country should be still preferred, even in the first year, the husbandman, in this case, should begin spread his ashes in the manner before directed, about Midsummer; as soon as the furnaces are cooled, without leaving any in the places where those furnaces stood. Immediately after, a slight ploughing, just sufficient to bury the ashes, should be given, with the precautions before mentioned with regard to the furrows. No more ashes should be spread at any one time, than the plough can cover in the same day. A few days after this first slight ploughing, a second should be given, somewhat deeper, in the same direction, and these ploughings should be continued, each going a little deeper than the former, till the ground be loosened to a sufficient depth. Two good cross ploughings will then be of excellent service: after which a fifth ploughing a-cross them, will bring them up to the direction they were in at first. The ground should be harrowed several times between all these ploughings, with harrows heavy in proportion to the strength of the soil; and if any hard clods have resisted the force of the harrow, women and children should be employed to break them, it being necessary to pulverize the soil as much as possible. I say, as much as possible, because that cannot be perfectly completed this first year. Perhaps the spiky roller would be of excellent service here.

The same women and children will also clear away all the stones, if there be occasion. Each successive ploughing will turn the stones upon the surface; but such only as are bigger than a man's fist need be removed. If any of the stones should be too large for the women and children to remove, the carters must take them up as they pass by; and if there should chance to be any under ground so large that the men cannot move or load them, they must be broke with sledge-hammers, and other iron tools proper for this work; or if they are great rocks, they must be blown up with gun-powder; for nothing should stop the progress of this undertaking.

The time to sow the land thus broken up for the first time, will always be a fortnight later than the common time of sowing other lands in the same country, with the same kind of grain. A few days before this is sowed, it should have another light ploughing; after which it should be sowed, in proper weather, with half the usual quantity of seed, whether wheat or rye, and this seed should be covered in, either with a plough, or with the harrow. Drains should also be cut in this land, in the manner directed under that article, as soon as possible, to carry off the water in the winter. If any very large clods are left on the ground, women and children should be employed to break them. This land being thus sowed, nothing more need be done to it till harvest.

The quality of the land must determine what sort of grain will be most proper for the first year's sowing in this husbandry. If the soil be rich, it will bear wheat: if of a middling quality, it will produce messin, or a mixture of rye and wheat, consisting of a greater or lesser proportion of either, according to the nature of the ground; and if it inclines to poorness, it will produce rye. These particulars may be judged of immediately after the burning. In general, unless the soil be very excellent, I would always advise the sowing of rye the first year. There will be a certainty to success with the grain; and the husbandman will be enabled by its produce, and by that ploughings, to judge what his land will be capable of doing the next year without running any

any hazard. This has been my method. I have also experienced, that the rye does much better than wheat in all light sandy soils thus broken up. When they are afterwards enriched to a certain degree, they become fit to bear meslin, and then wheat : though, if they should never produce any thing but rye, the difference would not be great in point of profit.

As soon as the ground is cleared, a light ploughing should be given it, to bury the stubble ; and some days after it should have a second ploughing somewhat deeper, but in the same direction. When this is done, two good cross-ploughings should cut the soil to the proper depth for sowing ; and a fifth ploughing, afterwards to be given, will leave the furrows in their first direction. Between these five ploughings, which are to be performed with the plough having only one fin to the share, the ground should be well harrowed several times, and the stones and roots picked out. All these ploughings and harrowings will pulverize the earth, and mix it equally with the ashes. If this land is to remain in ridges, the above will be sufficient till the sixth ploughing, which should be given it a few days before the sowing, and should be followed by the last, performed with the two-finned plough to bury the seed : but if it be sowed in broad lands, or quite flat, for former directions in that respect are to be observed here. In whatever manner any of these new grounds, broken up with the plough, are sown, they will not require near so many hands to break the clods this second year, as were necessary in the first. With regard to the quantity of seed, a little more may be sown now, that is, about a third part less than is a commonly used in the country, of the same kind of grain, for an equal extent of land.

The lands thus brought into tillage by means of burning, become infinitely better than other grounds, and produce much greater crops. This process improves the soil for upwards of twenty years. No weeds will spring up among the corn for a considerable time ; for there are scarcely any, even now, in the lands I first broke up. The vegetable food in the earth is not therefore wasted here upon useless plants, but serves entirely to nourish the corn, which accordingly shoots with redoubled vigour, produces well-filled ears, without the trouble and expence of weeding it ; and, when threshed, is so clean, that it needs only to be winnowed. The bread made of it is excellent, and of superior quality. When in process of time these burnt-lands shall produce as many weeds as other ploughed grounds, they will then be in the same degree of imperfection ; but it will be a long while before that happens ; even longer than I can say ; for I have not yet seen an instance of it. The remedy, however, is always sure and ready, namely, to let them rest two or three years, by which time they will have acquired a new sward, thick enough to be pared off, and burnt as before. This will restore them to their former perfection, without being near so expensive as the first paring and burning : for there will be no roots to grub up here, nor any stones to carry off ; nor will it be so difficult to break the now much fewer clods. I have managed in this manner with great success, where there has been a sufficient depth of mould, lands which had formerly been in tillage, and would no longer produce corn because they were exhausted, either by too many successive crops, or too great quantities of weeds. They are now as good as any other burned land.

Worn-out meadows, which I have restored by the same means, and formed a-new with grass-seeds, have yielded great quantities of excellent hay. I have collected plenty of this seed during some of the preceding years, from meadows which were not too wet. Several of my neighbours have practised the same method with equal success : and, in a word, it is the most powerful restorative for worn-out land.

From what has been said, it evidently follows, that the paring and burning of the surface of the earth, is, indisputably, the best and surest way, either to clear, or restore the soil. It is making a most advantageous acquisition to one's own estate, the value of which is at least doubled, and oftentimes quadrupled by this means. To enrich one's self, without doing it at the expence of any person whatever, and, at the same time, to enrich the state, is surely an action worthy of a true patriot, and of a respectable father of a family. This may be done by following the method here laid down ; a method which has been long known, though very superficially. I will venture to say, that it never was carried to the degree of perfection to which

my practice has brought it ; doubtless because none applied themselves particularly to it. *Memoire sur les Defrichemens.*

A correspondent of the editors of the *Museum Rusticum* has given us the following method of performing this operation in the fens of Bedfordshire.

"About the middle of May, says this gentleman, we plough the land for burning, which is sward-land, that has not been ploughed for four or five years, or perhaps a longer time : our ploughs are what are called Dutch ploughs, with a large share ; the edge and point are very thin and sharp, and are kept so by filing : the furrows should not be more than seven or eight inches wide, and an inch and a half thick, having as few baulks as possible. When it has lain so long that the fods or furrows are dry (in which the farmer's own discretion must guide him, it being impossible to point that out by words) it must be made into heaps about the size of middling grass-cocks, each person carrying on before him as heaps about seven furrows : the work will then direct him how big the heaps should be ; they should be made as narrow at top as conveniently they can, by way of prevention against wet weather. If every person keeps his work as to the number of furrows, the heaps will rise in regular rows ; but it should be observed to keep these rows in quincunx order (as represented on Plate II. fig. 7) that when you come to spread the ashes, they may cover the ground regularly.

When it is fit for heaping, the customary way of this country is to let the burning out to people, to burn and spread the ashes, which must be spread so as to cover the ground all over : the usual price is from four to five shillings per acre ; but that, in a great measure, depends upon the dryness or wetness of the season. It would, however, I think, be most adviseable, where hands are plenty, to do this work by the day, as you may then employ as many persons as you think fit ; for it should be burnt off with all possible expedition, because if it be long in burning, it is attended with bad consequence, which in rainy weather is hard to prevent ; it is therefore very requisite to pursue the work briskly, otherwise the grass-roots which lie below the reach of the plough, when ploughed for burning, will shoot out, and become almost as full of grass, as though it had not been ploughed at all ; then, when you plough it after the burning, instead of breaking so that the seed may fall into the cracks, it will turn up as strait as clay, and then no seed can grow any where but in the seams between each furrow.

When one side of the field is cleared, and the ashes spread, you must, as soon as there is room, get to ploughing and sowing the seed. Nor must the furrows now be wider than those already mentioned, and about two inches deep ; for as fen land in general ploughs tough, rather than breaks, you will have more seams than if the furrows were made wider : the custom with us is to sow the seed as soon as possible after the land is ploughed." *Museum Rusticum*, vol. I. p. 420.

BURNET, the English name of a plant, now greatly cultivated as a green food for cattle in the winter. We have given a figure of this plant taken from a specimen gathered in a field belonging to Mr. Rocque at Walham-green, on Plate III. fig. 12.

It is very natural to think that we have in England many sorts of grasses, which are well adapted to the climate, are wholesome food for cattle, and, with the assistance of proper culture, would produce very advantageous crops both to the grazier and farmer. We have, for many years, been sensible of the great advantages that result from the culture of saintfoin : in some soils lucern has been sown with considerable profit, and the Dutch trefoil is known to be excellent, when properly managed : but these only serve for green fodder in summer : they may, indeed, be dried, and made into hay, and in that form be reserved for the cattle's food in winter ; but this, independent of the inconvenience, trouble, and uncertainty, that attend the making and keeping it in proper order is not sufficient ; the farmer has also occasion for green fodder in the winter, and early in the spring, and that on many accounts, particularly for feeding such of his ewes as will yearn early in the year, as well as keeping them from losing their flesh after they have dropped their lambs.

A plant therefore which will not only live through the winter, but will also, if possible, vegetate in that season, cannot fail of being highly advantageous, provided it be at the same time a pleasing and nourishing food for cattle. All these properties have been lately found in burnet ; it not only preserves its verdure during the hardest frosts of our

Bent Grass.

our winters, but also increases in bulk, and grows, if the weather be all open and mild; and is now known to be an excellent food for cattle. The discovery is owing to Mr. Rocque, of Walham-green, who, at the request of the late Mr. Wyche, spent some years in endeavouring to find a plant that would prove an useful and succulent food for cattle during the winter; and, at last, fortunately discovered that burnet would answer the intention.

Mr. Rocque has also found by experience, that it will grow in the driest land: for he has planted some of it even in the gravel-walks in his garden, where every thing else is burnt up in the summer, but this never withers; one of the qualities of burnet being to continue in sap all the year. It is the opinion of many, who have seen the burnet of his raising, that if this plant is generally cultivated, there will never be a scarcity of hay in England, even in the greatest drought.

The land on which it is sown should be fine, because it is apt to shed, and it should afterwards be dried perfectly.

Burnet does not lose its leaves in drying; and though the hay made of it be sticky, it will, after threshing, be very agreeable to horses, which are so fond of it, that they never waste any. One acre will produce upwards of three loads of hay, and above forty bushels of seeds. Horses are fond of this feed than they are of oats: and Mr. Rocque is of opinion, that it is a more proper food for those who do not labour hard, because it is not of so hot a nature. Burnet bears seed twice a year, and will afterwards yield a good spring crop.

It is not only good for horses, but also for all manner of cattle, even for swine: and Mr. Rocque has experienced another virtue in it, which is, that, being stung by a wasp, the leaves of this plant rubbed pretty hard upon that part so injured, immediately took off the inflammation.

If the burnet does not grow equally every where, some plants must be drawn where they are too thick, and planted where they are thinnest: or the vacant spaces may be supplied from the nursery. If the land was not got in good order to sow the seeds at a proper season, the burnet may be transplanted at Michaelmas from this nursery, and set at nine or twelve inches distant every way, according to the richness of the soil.

The seed sown in May may be mowed at the latter end of July. That sown in June will yield a pretty good crop, and must be cut but once; and the same of that which is sown in July. The plants produced by seed sown in August should be mowed, to destroy the weeds. These mowings may either be given green to horses, or made into hay. The first spring cutting will purge horses; and Mr. Rocque believes it will also cure the grease: but it is only the first crop that purges.

Burnet should be mowed but once the first year, in order to leave it rank in the winter; and in this case it will be ready to feed in February or March, or to mow again in April.

If natural grass grows among the burnet, it may be harrowed in the same manner as lucern; for having a tap-root, the harrow will not hurt it: but it must not be ploughed, lest the roots should be broken in the ground.

When the seeds of this plant are to be sowed, it must neither be fed, nor moved, in the spring. The seed will be ripe about the middle of June, when it must be reaped like wheat, and threshed on a cloth. It should be threshed before it is too dry, because it is apt to shed, and it should afterwards be perfectly dried.

As a great deal has been written on the subject of burnet, we shall endeavour to set the whole in a fair light, by adding two letters, which were sent from gentlemen of known character and reputation, to Dr. Templeman, the late secretary to the Society of Arts, Manufactures, and Commerce. The first was from Davies Lamb, esq; and was sent in consequence of a letter sent to that gentleman by a member of the society, requesting his opinion with regard to the usefulness of burnet.

"My burnet, says Mr. Lamb, though very green and beautiful all the winter, made no great progress till the middle of April following, when I thought it absolutely necessary to feed it. I did so, but I did it too late, and kept my cattle upon it too long, from the middle of April to the 20th of May. This was a very great mistake; the burnet plants were now headed for seed, and the stock chiefly fed upon the heads, which greatly lessened my quantity of seed, as well as retarded the growth of the plants. I turned into the field, ewes, lambs, and calves,

and they all feed very greedily upon the burnet. From what I had heard of Mr. Rocque, I very much expected them to scour, but there was not the least appearance of it, and the cattle thrived accordingly.

The 6th of July I began to mow, the weather being favourable; six men and four boys threshed and cleaned the seed in seven days. I had 200 bushels of very fine clean seed, as many sacks of chaff, and seven loads of hay, from a field of seven acres and a quarter.

Satisfied that 200 bushels of seed would be more than I should be able to dispose of, I was not anxious after another crop, being rather desirous of seeing what it would perform as a pasture. Accordingly, in about ten or twelve days after the field was cleared, I turned into it seven cows, two calves, and two horses; they all thrived very remarkably, and the cows gave more, and we thought a richer milk than in any other pasture; I really expected (as burnet is so strong an aromatic) that the milk would have had a particular taste; but far otherwise: the milk, cream, and butter, were as fine, if not finer tasted, than any from the best meadows. I am satisfied, that there is no better pasture for cows, whether milch or barren, than burnet. The weather was now extremely drouthy, all our pastures were burnt up, yet the burnet flourished, and grew away, as if it had a shower every week. My stock of cows, horses, and calves, before-mentioned, pastured in it almost continually, till Michaelmas; by the middle of November it was grown so considerably, that I have again turned in six head of cattle, and if the weather is not severe, I am of opinion, it will maintain them till Christmas.

The burnet straw, or haum, is, after the seed is separated from it, a very useful fodder for horses, cows, calves, and sheep; the chaff is of great value, if mixed with any other, however ordinary chaff. I have fed all the above-mentioned stock with it promiscuously together in one field; putting the haum into racks, and the chaff into troughs, and if the haum was chopped with an engine, it would still be of much more value.

Burnet, I am fully persuaded, will prove a very great acquisition to husbandry on many accounts, but more particularly for the following reasons:

Burnet is a good-winter pasture, consequently it will be of great service to the farmer; as a constant crop it may be depended upon, and that without any expence for seed or tillage, after the first sowing: whereas turneps are precarious and expensive; and when they fail, as particularly this year, farmer is very often put to great inconveniences to keep his stock.

It affords both corn and hay too. Burnet-seed is said to be as good as oats for horses. I know they will eat it very well; judge then the value of an acre of land, which gives you at two mowings ten quarters of corn and three loads of hay.

The seed indeed is too valuable to be put to that use at present; though it multiplies so fast, that I doubt not but in a few years the horses will be fed with it.

It will bear pasturing with sheep.

It makes good butter.

It never blows or hoves cattle.

It will flourish upon poor, light, sandy, stoney, shaltery, or chalky land.

Burnet, after the first year, will weed itself, and be kept clean at little or no expence.

The cultivation of burnet is neither hazardous nor expensive: if the land is prepared as is generally done for a crop of turneps, there is no danger of any miscarriage; and any person may be supplied with the best seed by the seedsmen in the city of London, or the borough of Southwark.

I make no doubt but that burnet might be sown late in the spring, with oats or barley. A gentleman in my neighbourhood did so last summer, and it succeeded very well. I should think a buck-wheat season, which is sown the last of all corn, would suit it very well; but of this I have no experience, and could wish to have the experiment tried. A pea-field, drilled in rows, and kept clean, would make an excellent season for burnet, as the pea-crop would come off soon enough to prepare the land with two ploughings by the middle of August; after which time I should not chuse to sow it.

It very frequently happens, that every farmer who sows many acres with turneps, has several worth little or nothing; the fly, the dolphin, the black caterpillar, the dry weather, or some unknown cause, often defeating the industry and

X

expence

experience of the most skilful farmer. When this happens, as it too often does, I would by all means advise him to sow it with burnet, and in March and April following he will have a fine pasture for his sheep and lambs.

Burnet is a native of England, and will certainly perfect its seed twice in one summer; and a farmer, with a small plantation, may supply himself with seed of his own growth at very little or no expence: he may then be encouraged to make experiments in various seasons, without much loss or damage.

Thus, Sir, I have sent you a true account of the success of my burnet, and also my opinion of it. I wish what I have said may any ways contribute to dispel the prejudice, or inform the ignorance of my countrymen."

The other letter was from Christopher Baldwin, esq; of Battersea, a gentleman well known, and justly respected for his candor and fidelity.

"In the years 1763 and 1764," says Mr. Baldwin, "I made several experiments on burnet, with a view to make myself acquainted with its manner of vegetating, and the uses to which it might be applied: and having by this means acquired that knowledge I was desirous of attaining, I determined last year to lay down several acres with burnet; nor would I content myself with doing it in any one particular method: therefore in the beginning of July, 1764, I sowed about eight rods of ground with five pounds of Rocque's burnet seed. Rain falling soon after the seed was sown, the plants came up very finely, and thrived in such a manner, that I was tempted to plough up about an acre of ground and plant it that autumn, in order to see what effect the winter would have on the young plants. Accordingly, on the fourth of October I planted them in rows, about twenty inches apart, and about fifteen inches from each other in the rows. This distance, from experiments and observations which I have made, seems to me a very proper distance. These plants took very well, and through the winter thrived with surprising vigour. Last spring I ploughed the remainder of the field, being three acres, and planted it in the same manner with my plants, the whole of which, notwithstanding the uncommon drought of last summer, grew well, and the verdure of the plants was really very beautiful. No water was used; indeed it would have been a vast work in a field of that size: however, I never saw any need of it. The plants were once hoed, and stood over for seed, of which the quantity collected was not very great; but this must be attributed to the uncommon drought, for I think we had not above one shower of rain from the planting to the gathering of the seed, the whole of which amounted to about 160 pounds.

The seed being got, I was impatient to see how the cattle would take to it, as it was roundly asserted by some gentlemen, that no cattle would eat it. Accordingly, I ordered four cows and two horses to be turned into the field; the cows fed freely upon it, but the horses did not seem to like it so much at first, though in two or three days they fed well upon it. Burnet has strongly the taste of cucumbers, and I was fearful it might give a disagreeable taste to the milk; it therefore gave me great pleasure to find, in about four or five days, that the quantity of milk was not only much increased, but the flavour of the cream much superior to any I had ever had before, or ever tasted from cows fed upon the richest meadows. The cows and horses having fed down the field, it was hoed again, and then harrowed once over, which laid it very clean, nor could I find that the burnet was at all hurt by the harrow.

Here let me observe to you, that I fed my horses in the stables for about five weeks with the burnet straw, or rather haum, from which the seed had been threshed. These horses fed very freely, and thrived much upon it, though they had only half their usual allowance of oats. However, as I would by no means secrete any circumstance that may appear unfavourable to burnet, so I must tell you that I observed, when any friend called upon me, and their horses were put into the stable, that some horses eat very greedily of it, and others would not touch it. I cannot say this gave me much concern. I satisfied myself with thinking, that some horses did not know what was good for them; or to speak more seriously, I thought the novelty of the food might as much displease one horse, as it pleased another; and doctor Templeman knows, that there are some things which we loath as children, that we are fond of as men; and that there are some things which we as much dislike as men that are very wholesome food; but to come nearer to the point. It is well known some sheep and cows will not touch a turnep,

yet is any one weak enough to infer from thence, that turneps are an unwholesome or an improper food for cattle? And I was lately told by a particular friend, that he had often observed, when his horses had fed for some time on the faintfoin hay, that it was some days before they would again take to meadow hay. I should not have mentioned this circumstance of the horses, but to shew my impartiality; and I do it the more readily, as I find there are some gentlemen who are as fond of decrying, as others can be of promoting useful experiments in agriculture.

Being well pleased with the success that had attended my first experiments in the field, which I call four acres, I determined to proceed as I had intended in the spring of the year; accordingly, as soon as the oats were got off a field of twelve acres, I ordered it to be ploughed and sown with 160 pounds of burnet-seed before-mentioned. This field was sown on the twenty-sixth of August last; and no rain falling till the eighteenth of September, the plants did not appear till the twenty-eighth of that month: however, there seems to be a good crop, and I intend, as soon as they fresh up in the spring, to have the plants set out with small hoes (such as are used for carrots and onions) to about six inches apart. And in about a week after this is done, I shall harrow it with light harrows; far from experiments which I have made, this seems to me to be the best method of managing broad-cast burnet. Having nothing further to say in regard to these twelve acres, I must return to the four acre-field transplanted, which having been hoed and harrowed as before-mentioned, was laid up for winter food for my cows; but finding lately some gentlemen had again asserted, that sheep in particular would sooner feed on his quick-hedges than touch the burnet, I sent to a neighbouring farmer for his flock of sheep, and having a friend with me, we followed the sheep into the field, who fell upon the burnet so greedily, that we found it very necessary to send them home again.

Being very much vexed at these idle tales, told much to the prejudice of this (as it appears to me) excellent plant, I determined to put it to as fair a trial as I possibly could. Accordingly, I ordered in four cows, which were in a very good feed on natural grass, and had besides a large truss of oat-straw put in their cribs, every night, notwithstanding which they gave very little milk, and indeed were almost dry. These cows, I declare, had not been in the burnet above six days, before they gave much more than double the quantity of milk; nay, was I to say three times the quantity, I know I should not exceed the truth. The milk is exceeding fine, and free from all bad taste: and further, I must observe, that they soon began to leave half their straw in the cribs; so that they are now served with only half the quantity they had before. My land is a poor dry upland gravel; there are millions of acres in this kingdom of better land, that do not fetch two shillings and sixpence an acre. What a field therefore is here for improvement! Nay, I cannot but observe with amazement, the great numbers of country gentlemen who daily flock to this great city in pursuit of trifles, when they have such inexhaustible funds of knowledge within themselves, if they would properly make use of them: confident I am, I could point out methods of improvement that would surprisingly better their estates.

As the account I have now given you of burnet may appear a little extraordinary to some of the worthy members of your society, so I shall be far from being displeased at their even doubting what I have now said: on the contrary, it will give me pleasure, provided any gentleman, who have such doubts, will do me the favour to call at my house, and convince himself by ocular demonstration of what I have now said."

Mr. Young, in the second volume of his *Annals of Agriculture*, gives the following account from Mr. le Blanc of Cavenham in Suffolk, which Mr. Young vouches for the accuracy; he says, "It having been remarked, that sheep eat spontaneous burnet when it is young, though they refuse it when advancing to seed, I formed an experiment to know what probability there is of its being a proper plant to lay down poor sandy lands with. In October, 1782, sowed a space, several perch square, with burnet-seed and rye, being a part of 100 acres laid to ray-grass, trefoil, and white clover: the soil a blowing sand upon a chalk bottom, worth about 3s. 6d. an acre. It was sowed for the rye.

The 5th of April, 1784, my flock, of between six and seven hundred sheep, were turned in. The grasses were in general backward; but the burnet in its growth much for-

forwarder than the rest: for the first two or three days they did not eat it at all; a fortnight after I viewed it again, and found the burnet-eaten to the ground. June 4th, examined it again, and found it pared close. When a flock has so large a range as 100 acres, and eat up the growth of any small spot so clean, it is a far more satisfactory proof that they have no dislike to the plants growing there, than if they were confined to a small field with no other herbage; to some experiment of which sort, the notion is probably owing that sheep will not eat burnet. I am so well convinced of the contrary, that I intend sowing a much larger quantity of it."

Mr. Young, in his *Annals of Agriculture*, makes the following observations: "On three fourths of the sheep-walk lands in England, in a regular course of tillage, or permanently laid, ray-grass is the only plant used; sometimes broad clover, upon soils much too poor for it. I shall not condemn ray-grass, because I know its value early in the spring when other food is scarce; but, in the preceding experiment, my worthy friend observes (and I believe the fact is always so), that the burnet was forwarder than the ray-grass. Granting, however, the necessity of some ray-grass, is it not a very capital object to introduce other plants, not so exhausting, that shall have the same or superior qualities? Experiments and observations have been made in most parts of the kingdom, that prove the exhausting quality of ray-grass; its narrow leaf, and fibrous root, class it in this respect, as well as its botanical arrangement with corn; but the broad leaf of burnet, and its deep carrot root, indicate the contrary effect; and accordingly, in several trials that have been made, it has been found to ameliorate. The poorest soils in the kingdom agree well with it; even such as are too poor to produce any other herb. The hot pungent quality of the plant has been found exceedingly beneficial to sheep touched with the rot.

As to the trials, or rather assertions, that were for some years made against this plant, they certainly resulted from attempting to feed it when too much grown. If it is suffered to run to seed, nothing will touch it; the right and only time for sheep, is while it is in its young yellow shoot; in that period of growth I know nothing that refuses it. The greatest obstacle to its culture, is the seed being 1s. per pound: and this is owing to the mistaken idea which is common, of its not possessing the merit that really belongs to it. The price was once only 4d."

Mr. Young, in the same volume, from the Minutes of the Husbandry at Holkham of Mr. Coke, who formed an experiment, to see expressly what was the merit of burnet, says, that Mr. Coke, with the noble spirit that characterises his husbandry, sowed 40 acres, mixing a small quantity of white clover and rib-grass with it. The result was as decisive as can possibly be imagined; the field has been fully and incessantly stocked with all sorts of cattle, especially sheep, and is constantly pared as close to the ground as a favourite spot in a pasture is by horses. This proves, in the clearest manner, the value of burnet, and confirms the opinion of Mr. le Blanc, that it is one of the best grasses for sheep.

The preference which sheep give to these plants on comparison with common clover and ray-grass, is remarkable. The 30 acres first laid down in the midst of a large field, sown in the common manner, afford a constant opportunity to remark this. The flock kept almost constantly upon that piece; if they were driven into the clover and ray-grass they presently returned; it is within sight of the house, and we remarked them, during three days, to be regularly on those 30 acres. Mr. Coke assured us, he had rarely failed to make the same observation.

The following experiment on burnet was made by Mr. Pitt, of Pendeford in Staffordshire, and communicated to the public by Mr. Young, in his *Annals of Agriculture*, vol. I. The cultivation of a large stock of green food for cattle during the winter-months, is one great desideratum in the farming business; indeed the absolute necessity of having such food for the support of fat sheep, ewes, and lambs, and milch-cows, is obvious and well known, as they cannot possibly be maintained, without either green food or corn; the substituting the former instead of the latter as much as possible, is the interest of every individual concerned in the business; and very much so of the community in general.

Turneps are admirably adapted to the above purpose, yet the quantity of those which every farmer can regularly cultivate is, in general, limited, besides the casualties the crop

is subject to from flies, caterpillars, &c. as well as the very great destruction of them by severe frost, of which, with us, we have a recent instance; and they are totally useless in the case of milch-cows, from the unsufferable taint they give to the milk and its produce.

It is seldom we can have our clover and ray-grass fit for pasture earlier than the beginning of May: I have tried tares, and find them little or no earlier: cabbage would answer the purpose better, but requires a good deal of dung and labour. I have, therefore, made the following trial of burnet, but not yet with all the success I expected.

In the month of April, 1783, in the midst of a field of barley, I sowed an acre of burnet instead of the usual seeds, the remaining part of the field being seeded with clover and ray-grass; the seeds came well, and the following autumn it was pastured with sheep and horned cattle; I observed the sheep preferred the clover and ray-grass, but the horned cattle seemed to prefer the burnet; it was hayed up at Christmas, and, notwithstanding the extreme inclemency of the winter at Lady-day, the burnet was what we term good picking for cows, which, however, I did not pasture, as I mean preserving it for seed: it evidently preserves its verdure in severe weather much beyond clover, yet the clover now gains ground of it, and I expect, by May-day, will at least equal it, the burnet being apparently of flower growth, I suspect the species I have made trial of (the seed of which was procured from Holland) to be of a dwarf kind, yet some plants which I have stuck in a border of the garden are shooting out vigorously. As I think there is a probability of the plant being rendered extremely useful, I wish gentlemen, whose situation and connections give them opportunity of procuring the different species of the seed, would make trial of them; and communicate the result of their experiments:

The species I have tried, I am pretty confident; have no chance of producing a crop the first season, if sown by itself: I sowed a small quantity by itself in May, which was little forwarder than that sown with barley: I also sowed two lands, soon after Midsummer, in the middle of a field of turneps; the turneps came to a crop, but the burnet to little; of a small quantity sown in the garden early in the spring, some perfected its seed, and some not. I am now making trial of it in the following manner: I have frequently observed, running a light pair of harrows over wheat, rolling it afterwards, has been of service; upon a few acres of my clover-lay wheat, I have, therefore, scattered the seed of burnet, light harrowing and rolling it in; by preserving the stubble during the autumn and winter, I hope to have good picking for cattle, for the months of March and April, and shall afterwards plough up and work the land for turnep fallow; if it answers my expectation, I would regularly have 20 acres in this course, whereas I should lose no crop, and incur little or no extraordinary labour; my greatest doubts arise from the slow growth of what I have made trials of. If any species could be found of more luxuriant growth, I have no doubt of its being a plant highly deserving attention.

Mr. Pitt says also, in other communication: "A neighbour of mine has observed the following valuable property in burnet as a meadow grass; namely, that it preserves the hay from over-heating in the stack; and that the hay of a meadow in his possession, which contains naturally a considerable portion of this grass, always comes out of the stack of a fine green fresh colour; while his other hay, equally well made, and the same in other respects, but without this plant, shall over-heat and come out quite brown: he is so thoroughly convinced of this fact, that he has this season bought from me a quantity of the seed, to mix with the other seeds in laying down a piece of land for meadow. I have observed, that the plant itself makes very good hay, and even after threshing out the seed, is eaten as clean up by horses as the best hay or clover; but the plant is less luxuriant in its growth than the broad red clover, the product per acre not exceeding two thirds of the product of clover in the same field. I think the plant a good one to sow instead of ray-grass with clover or trefoil, being abiding, very early in the spring, extremely hardy, bidding defiance to frost, and sustaining the chilling blasts of the east-wind without fading; the trial of it on clover-lay wheat failed, it being choked by the natural grass which generally abounds in clover-lay wheat substance.

BURNING of heath, a common practice of the country people for clearing heathy ground, in order to procure grass and herbage for their cattle.

The

The fittest time for burning commons is towards the latter end of the summer, when the plants are withered. But great care must be taken that the fire extends no farther than is intended.

This care consists chiefly in clearing away all the grass, &c. on the side you would preserve from the flames, to a distance sufficient to prevent all communication. The grass, &c. cut down there should be spread upon the part intended to be burnt, which will serve to kindle the fire after it is dry.

Besides this precaution, a fair calm day must be chosen; when by kindling the fire on the side the wind blows from, you prevent its spreading any further that way, and see it gradually remove up into the heath or common. The fire should be carefully watched for fear of accidents. But if, notwithstanding these precautions, it should spread to places intended to be preserved, and no water should be at hand, the most effectual way of stopping the progress of the fire, is to dig a trench: for by throwing up the earth on the side where the fire is, you cover the grass, and thereby hinder the flame from extending any further.

BURNING of lime, Mr. Marshal, in his Rural Economy of Yorkshire, says, is essential for the farmer, and is the sheet anchor in the Vale Husbandry, where lime is used invariably on every species of soil, and is in most cases with great success. In giving a detail of this operation, the following observations will be requisite:

1. Building the kiln.
2. Raising and breaking the stones.
3. Coals and their proportion.
4. Filling the kiln.
5. Drawing the kiln.

1. *The kiln.* The materials are either limestone entirely, or limestone lined with bricks on the inside. Neither timber nor mortar ought to be used in building a lime-kiln; the former presently decays, and the latter, by alternately swelling and shrinking, bursts the walls; besides rendering them in the first instance too tight to admit a proper quantity of air: no other air-holes than the eyes at which they are kindled being made in the kilns of this district.

The form of the cavity is an irregular cone inverted. At the bottom are generally two eyes opposite to each other; the cavity being here contracted to a thin point, or narrow trough; the width, that of the eyes. As the walls are carried up, the cavity takes by degrees a circular, or sometimes an oval line; at the same time receiving, as it rises, a conical form; until having reached somewhat more than half its extended height, the form is changed to cylindrical; or is sometimes contracted towards the top. The proportion between the depths and the diameters of these kilns that of the depth, being generally about one and a half diameter of the top.

The size varies from six to forty chaldrons.

2. *The stones.* The art of raising stones can only be learned by experience in the given quarry in which they are to be raised. They are sometimes raised by the day; sometimes by the load; but most generally the entire labour of burning is taken together at so much a chaldron of lime.

The breaking of hard strong stones is a laborious part of the operation of lime-burning. On the north-side of the Vale it is done by men with large sledge hammers; but on the Malton side, where the stone is soft, women are frequently employed in breaking.

The medium size is that of the two hands; but men burning by the chaldron will not, unless well attended to, break them so small: stones nearly as big as the head are sometimes, but very improperly, thrown into the kiln; for unless the proportion of coals be unnecessarily large, the outer shell only is burnt to lime, the core remaining a lump of unburnt stone.

3. *Coals.* The Morelands for the last fifty years, have furnished the north-side of the Vale with coals for lime-burning, and for an inferior species of fuel. The seam of this coal is thin, and the quality in general very ordinary.

Before the discovery of these coals, lime was burnt with furze and other brushwood; but notwithstanding the Morelands are now nearly exhausted of coals (unless some fresh discovery should be made), the district is relieved from the apprehension of returning again to its ancient mode of burning lime. The Derwent, besides an ample supply of coals for fuel, brings an inferior kind (both of them raised in West-Yorkshire) for the purpose of lime-burning. The

eastern end of the Vale is equally fortunate in this respect, by having the port of Scarborough in its neighbourhood.

The portion of coals and stones varies with the quality of the coals, and likewise, but in less degree, with the quality of the stone: the method of burning, too, varies the proportion. Three chaldrons of lime from one of coals (the measures equal) may be considered as the mean produce. From two and a half to three and a half for one, includes the whole extent of produce of well-burnt lime.

4. *Filling.* Some kindling, and an extraordinary proportion of coals being used at the eyes, and at the bottom, the kiln is filled up with stones and coals, in thin alternate layers; those of stones five or six inches thick, with coals in proportion; the coals, if not sufficiently small, being previously reduced to a gravel-like state; in order to run down more freely between the interstices of the stones, and thereby to mix more evenly with them.

The materials are cast into the kiln with large scuttles, which are filled with stones, by means of an iron-toothed rake, composed of four teeth about six inches long, of a head about a foot long, and a handle about four feet long.

If several men be employed in filling a kiln, it is common for each man to fill and empty his own scuttle. But this is an uncertain, and therefore an improper way of proceeding. Much depends on the regularity and evenness of the layer, and the due proportion of coals; and to judge of this with sufficient accuracy, requires some experience, and a steady eye; especially when the kiln is on fire, and the cavity to be filled up is full of smoke. If more than one person be employed in this case, it is highly probable the work will be imperfectly done.

Among the sale-kilns about Malton there is an excellent regulation in this respect. The scuttles are all filled, and brought to the top of the kiln, by women and boys, who deliver them to the master, or his foreman, standing there to receive them, with his eye fixed within the kiln; by which means he is enabled to distribute the stones and coals with the greatest accuracy.

5. *Drawing.* There are two species of kilns; or rather one species used in two different ways.

A kiln which is filled, fired, and suffered to burn out before any of its contents be drawn, is called a standing kiln.

If the contents be drawn out at the bottom, while the upper part is yet on fire, the vacancy of the top being repeatedly filled up with stone and coal, as the lime is extracted at the bottom, the kiln is termed a draw kiln.

Since coals have been used in the burning of lime, draw-kilns have, until of late years, been most prevalent. But at present standing kilns are most in use.

The reasons given for this change of practice are these: first, that the lime is burnt even in standing than in draw-kilns; in the drawing of which the stones are liable to hang round the sides of the kiln; those in the middle running down in the form of a tunnel, thereby mixing the raw with the half-burnt stones. The consequence is, the outside are burnt too much, the inside too little; the stones too frequently running down to the eye in a half-burnt state. Secondly, the unevenness of surface left by this method, together with the obscurity caused by the smoke, render the filling difficult; under-burnt stones, or an unnecessary waste of coals, is the inevitable consequence. A third argument in favour of standing kilns is, that a greater proportion of well-burnt lime may be produced from the same quantity of coals. It is allowed that more kindling fuel is requisite, and, at the bottom, a greater proportion of coals; but the fire by this means getting a strong head, a less proportion of coals are required in the body of the kiln; and what, perhaps, is of still more consequence, less heat is lost at the top of this than of the draw-kiln, which is always uncovered, and too frequently hollow and full of cracks; while the top of the standing kiln, being piled up in a conical form, and closely covered with sods or rubbish, collects a greater body of fire, and keeps in the heat more effectually.

One circumstance, however, relative to the standing kiln, requires to be mentioned. The inside should be lined with brick; for every time a kiln which is lined with limestone is suffered to go out, a shell of lime peels off the inside; by which means the walls are soon impaired.

The lime is drawn out at the eyes with a shovel, and generally carried out in scuttles, or in basket measures, to the cart or waggon.

Of a living kiln the drawing is generally continued until red ashes begin to make their appearance.

But standing kilns are suffered to burn undisturbed until the fire go out; except, perhaps, when the fire is rising toward the top, and a fresh supply of air is wanted, a few shovelfuls are drawn at either eye, by which means an internal hollowness is formed, and fresh vigour given to the fire.

From these circumstances it is plain, that a regular supply of lime cannot be had from less than three standing kilns; one filling, one burning, one drawing. The smaller burners, however, have frequently only two; and for a farmer, one, proportioned to his farm, is sufficient. About Brotherton and Nottingley, near Ferrybridge, from whence vast quantities of lime are sent to distant parts of the Vale of York, particularly towards Easingwood, the kilns are very shallow and wide; the cone of materials piled above the surface, being to appearance equal to the contents of the kiln. This renders the emptying of the kiln very easy; the lime being all thrown from the surface, or through a kind of door-way in the side; not drawn out of the eyes; which are in this case of no other use than to kindle at, and to admit of a supply of air. Those kilns are much less expensive than the kilns of this district, and more convenient. But query, Do they give as much heat with the same quantity of coals as a taller more cylindrical kiln?

Cost and price. The ordinary wages for the whole labour of raising, breaking, filling, and drawing, is 18d. to 20d. a chaldron.

At Malton, the labour, if taken by the gross, is about 18s.; the price of lime-kiln coals, with carriage from the keels to the kiln, about 14s. a chaldron (of thirty-two bushels) the produce better than three for one. The whole cost about 6s. the selling price 7s. a chaldron.

At Pickering, the labour is 20d. a chaldron: the price of moor coals and carriage 16s.; of Malton coals and carriage 18s. The produce, if sufficiently burnt, three to one. The mean cost is therefore about 7s. 6d. the selling price 8s. a chaldron. The building and repair of kilns, the wear of tools, the value of the stone in the quarry, and, in some cases, the carriage of it from thence to the kiln, are drawbacks upon the profits which appear in the above calculations. If therefore the stones be sufficiently burnt, the neat profit is in this case very small. Nothing, perhaps, would increase the profits of lime-burning in this place more than the kiln being filled by the hand of the master, or some judicious person not interested in a waste of coals. It is the interest of men who burn by the chaldron to underbreak the stones, and to make up for the deficiency of labour by an increase of coals; which likewise will make up for neglect, or want of judgment in filling. Let the stones be raised and broken by the chaldron, or the kiln; but let the filling be done by women and boys; by which means industry will be encouraged, and the stones, by passing under the master's eye, will of course be rejected, if not sufficiently broken.

BURNING of land. See the article BURN-BAKING.

BURNS. are accidents that often happen to animal bodies, whereby a solution of the continuity of the parts is produced.

In burns and scalds, when the skin remains entire, let the part be bathed well, and kept wrapped up in rags dipped in spirit of wine camphorated. Salt bound thick on the part has also been found very effectual for this purpose. Indeed all saline and spirituous applications excel all others, while the skin is yet unbroke; but when the skin is separated, anoint the part, and keep it constantly supple with linseed or salad oil, and a plaister spread with bees-wax and oil. If the skin be so scorched, that sloughs must be digested out, dress the wound with the wound ointment and oil of turpentine, and finish the cure with any drying ointment.

The fire supposed to be left in the part after injuries of this kind, is nothing more than the inflammation, which is the natural effect of such causes: so that the whimsical notions and conceits concerning fire remaining in the part, is extremely absurd. *Bartlett's Parriery, p. 251.*

BURNT-CLAY, a manure proper for close compact soils, which it opens, warms, and invigorates, and thereby disposes such lands to part with their vegetative virtues.

A correspondent of the editors of the *Museum Rusticum*, tells us, that he has experienced the efficacy of this manure on wet cold land; and gives the following method of preparing it:

"I caused, says he, a labourer to dig as much clay as made a number of walls nine inches high, the same in thick-

ness, and placed at the same distance from each other, in the same parallel direction; forming a square of about three yards. These vacancies, being like tunnels of brick-kilns, I filled with brush-wood, and on that threw some cinders or small coal, of which I had sufficient quantities, living then near some collieries; after which I covered the whole square with clay about three inches thick, leaving the ends of the tunnels open, which I then lighted on the windward side: as soon as the fire had got sufficient head, I stopped the mouths of them; and when I perceived the covering was almost burnt through, I had a small sprinkling of cinders or small coal thrown on the heap, and then another covering of clay of the same thickness; and thus I went on till my fire was seven or eight feet high.

"When I found my fire was very well kindled, which was commonly about the time I put my second coat on, I used to enlarge the base of the fire, by continuing the tunnels, and by adding new ones to the sides (which were filled and covered as the others, and then lighted), till I made my fire about seven yards square; for I soon found it never burnt well in the middle, if it was too large at first.

"Care should be taken that the labourer does not put on too thick a coat at once, as it will be apt to smother the fire: besides, by confining the heat in too much, the clay was apt to run and vitrify, which was then of little use.

"As soon as the heap was sufficiently cool (for the sooner it is laid on the land the better), I put about ten large cart-loads on a statute acre, and found it an admirable manure for either meadow, pasture, or corn; for the latter it will not last longer than three crops, though longer for the two former, and with this I have made prodigious improvements; but I do not believe it will answer for a sandy soil, as it will render it still lighter.

"This manure I burnt all times of the year, though flower in the winter than summer, but always fastest in windy weather.

"This I fancy may be burnt with brush-wood, or furze only; which I apprehend will answer better between the coats than coal, as it will keep the clay more open." *Museum Rust. vol. I. p. 407.*

BURNT-grain, a distemper common to corn, and too often confounded with smut, though it is, in fact, very different, and much more dangerous.

The smut, properly so called, occasions the total loss of the distempered ears; but as the black dust is very fine, and the particles of it have no cohesion, the wind and rain carry it off, so that scarcely any thing is housed in the barn, &c.

The burnt-grain is, on the contrary, often laid in the granary with that which is sound, to which it communicates a contagious distemper, and also darkens the flour, and gives it a bad smell.

The characters of this distemper are, 1. The plants that produce burnt ears are strong and vigorous.

2. The infected ears are not at first distinguishable from those that are healthy; but when they are past their bloom, they appear of a deep green colour, approaching to blue; they afterwards become whitish, and are then easily known. As this change of colour is effected by the sun, when a number of white ears have been suddenly perceived in looking over a wheat-field, the sun's heat has been often thought to cause this distemper, or a fog preceding that heat.

3. Though all the ears produced from one grain are commonly infected, yet M. Tillet, Aimen, and myself, have met with sound ears on plants that had produced others which were infected. We have even found some ears, part of which only were vitiated, and finally some grains inclosing partly a white flour, the remainder black dust.

4. In burnt ears, the chaff, or outward coat, was commonly found, with this single difference, that when the ears were near ripe, it appeared more withered and dry than in the healthy ears.

5. The bran, which immediately inclosed the grain, is not destroyed, as it is in the smut, properly so called; but has confidence enough for the grain to preserve nearly its natural form, with a whitish look.

6. The burnt grains are shorter, rounder, and lighter than such as are uninfected: they are sometimes larger, sometimes smaller. The furrow which runs the length of a grain of wheat is sometimes totally effaced, at others is visible: the pistils at the extremity of the grains are dried up.

7. The bud of burnt-grains is not visible.

8. Till the blooming season, there is very little difference between the burnt-grain and that which is healthy: they are only a little more swelled. But in the blooming season, the infected ears assume a bluish colour; the chaff

is more or less specked with small white spots: the grains are of a deeper green, and larger than a state of nature; and, as long as they preserve that colour, they adhere strongly to the chaff. The distemper has often attacked very young ears, while yet inclosed in the sheath. The stamina on the sides of the grain are then dried up and sickly; the embryo in part takes the deep green colour above-mentioned; the infected ears have not the consistence of those that are healthy; in the same measure the distemper advances, the chaff becomes dry and whitish.

9. The grains have some degree of firmness. On opening them, which may easily be done with the nail, there appears an unctuous, dark, brown, stinking substance, not at all resembling the light dust of smutty ears; the dust of burnt grain has some cohesion, and through a microscope appears to consist of larger particles than that of the smutty ears.

10. Some time before the blooming season, the grains appear to be filled with a whitish substance, a little burnt towards the bottom, and this colour extends by degrees over the whole ear: the grain then appears divided, as it were, into equal quarters, by furrows; which disappear as the grain increases in size.

11. By what has been said, it is evident that smut infects corn much sooner than the burnt grain.

12. Grains that are much burnt are evidently incapable of sprouting. But I have had some sound grains taken from an ear greatly burnt, which, in a kitchen-garden, have produced very strong plants; and though the birds disturbed my experiment, it appeared to me that there were some sound ears among many more that were infected.

13. A part of the burnt-grain is bruised by the flail, and their black dust is scattered over the sound grain; this unctuous dust chiefly sticks to the hairy extremity of the grain near the bud; it there forms a black spot. Corn so affected, is called spotted grain: many of the grains which escape the flail remain entire, on account of their lightness; a great deal is separated by throwing, but the spotted grain remains as well as many that are burnt: and this is enough to darken the flour, and give it a bad taste.

14. To remedy this inconvenience, and make the best bread, they pass the corn through drum-sieves (*cribles a tambour*) made of pierced iron-plates, like the graters with which they rasp tobacco; the corn is then washed, and all the light grains that swim skimmed off, which are mostly burnt. The water takes off the spots, which are but superficial; for if a spotted grain is wiped, the spot immediately disappears.

With respect to the cause of this distemper, I confess we are hitherto as much at a loss as in the case of smut. Some have attributed it to dung; others to fogs; many to the heat of the sun; some to insects; others to the moisture of the land; and not a few to the seed not being ripe: but these opinions are confuted by good observations, and by experiments very carefully made. We refer to what has been said of smut.

It may seem improbable that a mere superficial dust, that only sticks to the bran, without penetrating the grain, should be so contagious as to infect all the grain it touches, with a distemper; what is more surprising is, that it should injure the organs of fructification only. Yet, however improbable this may appear, the experiments made by Mons. Tillet put it past a doubt; they shew that the farmers are not without reason cautious in avoiding to sow spotted grain.

As it would take up too much room to mention, at large, all the experiments made by M. Tillet, which are to be found in the papers published by him on that subject, I shall content myself with relating the result of these experiments, and the inferences this able naturalist draws from them.

Several writers having mentioned dung as the immediate cause of this distemper, and others having asserted that it was hereditary, all M. Tillet's experiments were calculated to clear up these two points: he was at the same time in hopes, by means of the same experiments, of finding some method of guarding against this terrible distemper.

1. The several kinds of dung had no visible effect in producing burnt-grain. The infected seed produced as much burnt-grain in the ground that was not dunged as in that which was. He did not find that dung had any effect, either in favour of, or against the distemper.

2. Dung made of the straw of infected grain, did not seem to communicate the distemper; but the infected straw unrotted seemed to communicate it. Yet the effect

was most visible when the dust of burnt ears was mixed with the earth.

3. All grain naturally spotted, whether it grew on the land, or was brought from another place, bearded wheat, summer wheat, and wheat without awns, produced a great deal of burnt-grain.

4. Picked wheat taken from the finest ears, and carefully selected grain by grain, that none of it might be infected, being sowed, some in dunged, and the rest in undunged beds, without having received any preparation, yielded little or no burnt-grain.

5. Some of this same picked wheat being sprinkled with the dust of burnt-grain, produced as many distempered ears as that which was naturally spotted.

6. The picked wheat, being prepared with lime and a solution of the sea-salt, yielded still fewer infected ears than when unprepared.

7. There were still fewer from what was prepared with lime and nitre.

8. Early or late sowing seemed to be a matter of indifference.

9. It appears, by M. Tillet's experiments, several times repeated, that the dust of burnt ears is contagious, since found wheat sprinkled with it, or sowed in rills in which that dust had been put, produced a great number of infected ears. He also found that this dust, though exposed to a strong heat, as of sixty degrees, is still contagious, unless it is absolutely burnt by the fire, when it has not that effect. Though it is kept for years, its infectious quality continues as strong as ever.

10. Some farmers wash their sacks in which they put their seed. And it appears by M. Tillet's experiments, that they are in the right; for if the sacks had any of the dust on them, it would certainly infect some of the seed-corn.

11. M. Tillet thinks he has observed, that the infected plants are more susceptible of injury from frost than others.

If this is the case, hard frosts must be serviceable, since by destroying the infected plants, they would have the same effect, as if such plants had been all pulled up. The land being cleared of these useless plants, would be better able to supply such as are sound with nourishment, and the crop would be exempted from infected ears, which are a great hurt to it.

12. The black dust so contagious, is not so to rye or bere; but the dust of darnel is pernicious to wheat.

13. Smyrna wheat is less subject to this distemper than other grain; but summer wheat is greatly injured by it.

It must be allowed, that the knowledge which has been acquired of the cause of this distemper, has put the curious observers in a train of finding proper preservatives. In fact, as the dust of burnt-grain infects all the grain it touches, it is probable that every method should be deemed efficacious, that is capable of taking away this dust, provided the virus has not from its first contact affected the interior part of the seed intended to be sowed. In this case the several sieves which we have recommended to be used in the preservation of corn, and the washings with fair water, which in many places is used on spotted grain, may be mentioned as efficacious preservatives, as well as lime-water which our farmers use, the strong brine used in some provinces of France, and the solution of arsenic, of which some persons have made such a secret: all these preparations should be of service, and, according to M. Tillet's experiments, they are so: yet they are often insufficient. This point, therefore, merited to be cleared up by particular experiment, and with all necessary care. M. Tillet set about it with spirit, and the following are the inferences that may be drawn:

1. The effect of the black dust on the seed is only superficial, till it is put into the earth, not at all affecting the interior parts.

2. Therefore every means that can tend to clear them of the dust, must be of service to keep them healthy and free from the distemper.

3. Grain perfectly free from this, and from rottenness, will yield no distempered plants.

4. Grain blackened with this infectious dust, may be made healthy by clearing it of such dust.

5. Sifting seed, and washing it in several waters, lessen, it is true, the effects of the contagion; but this is not sufficient, as many infected plants will be produced, though the seed was washed in several waters.

6. Lime, which is more efficacious than water, is not always

always enough so. I shall observe, on this occasion, that seed was formerly limed in a manner different from what it is now. The seed was then put into baskets, which were plunged into lime-water very hot. The seed was stirred in the baskets, and all that swam on the water was taken out with a cullender; by this means they got rid of the infected grain; and the good seed was better cleaned, than by only throwing, as they do now, lime-water on a heap of seed, which is then stirred with a shovel, or by only mixing the seed with the slacked lime reduced to powder.

One of our farmers, a careful man, being obliged one year to sow spotted seed, he limed it by immersion, in the manner above described; and the year following had no burnt-grain.

Some experiments made in the county of Caux, by M. de Gouffreville, have been published; they evince the good effects of lime used in the manner we have mentioned. And what is still a farther confirmation of this is, that whenever our farmers sow seed that has not been limed, their fields are amazingly infected.

7. It is a good precaution to wash spotted grain in several waters; but it should be soaked in brine, and this brine should be absorbed by lime by immersion, as we have described.

8. A strong brine of sea-salt is very good, and may be employed to great advantage in countries where salt is a merchandize.

9. One part of nitre to nine parts water is more efficacious than sea-salt; this, therefore, should be used where nitrous earths abound.

10. Strong alkaline lyes are still better; salt-wort, potash, ashes of tartar, lyes of common ashes much impregnated with salt and human urine, or cows urine alkalised by putrefaction: of these various articles such may be chosen as are most common. For instance, in Normandy ashes of sea-wrack, which are very cheap there, may be used. This, which is rejected for dying and lyes, as being more impregnated than alkaline with sea-salt, may be advantageously used in the preparation of seed.

11. As it is evident that seed picked with care yields very few infected grains, it must, of course, where a farmer has spotted grain, be of great advantage to him to change his seed, in order to procure what is uninfected.

12. M. Tillet's process may be comprehended in what follows: if the seed is spotted, it should first be washed in several clear waters, till the black is quite got off; it should then be put into the steep. If it is not spotted, soaking it in the following liquor will be enough. Make some lye, such as is used for linen, in a bucking-tub, putting four pounds of water to every pound of ashes. If one hundred pounds of ashes are used, and four hundred pounds of water, there will be two hundred and forty pounds of lye, to which must be added fifteen pounds of lime, which will be enough to prepare sixty French bushels of wheat (between sixteen and seventeen bushels English measure). When this steep is to be used, it must be heated as hot as you can bear your hand in it; the seed, being put into baskets, must be plunged into it, and stirred with a stick; the baskets must then be raised and kept up by sticks on the edge of the bucking-tub for the lye to drain: the seed being thus prepared must be laid on the floor of the granary till it is dry enough to sow. If it is prepared long before it is wanted, it must be, from time to time, stirred with a shovel to prevent its heating; with this precaution it may be kept a month, or even a whole year.

We prepared some seed in this manner at M. Taponat's, near Rochefoucault in 1760; and in 1761 we saw with pleasure that the corn so prepared was uninfected; whilst in the neighbouring fields, a fourth, a third, and even half the crops were spoiled by this distemper.

All the trials that have been made evince that acrid substances are proper remedies for this distemper: I also believe all the steeps to be good; but prefer M. Tillet's as being more acrid, and least costly. I imagine lye that had been used for linen might do, only strengthening it with some sea-wrack, and putting twice as much lime. I know this lye to be very acrid, but cannot answer for its efficacy in preserving corn from being burnt, because for several years past we have scarcely had any of our grain so infected.

13. Several farmers in different provinces have used a solution of arsenic to prepare their seeds. Great complaints have been made in all quarters of it. Among others, a

physician published an *Essay* to shew of how much importance it was to prohibit the use of this poisonous steep. He there enumerates all the accidents that have happened to the sowers, and to the men that made the preparation, of which himself was a witness. Since M. Tillet has given us a method simple and innocent in itself, but little costly, and of great efficacy, to clean spotted grain, it is to be presumed that no body will use this pernicious drug, from which such melancholy consequences may ensue, if by accident any of it should be mixed with the meal, and if the light corn is given to the poultry or cattle; besides, this poisoned seed must kill all the partridges and pigeons that eat the uncovered grain.

As some people are fond of making objections, it may, perhaps, be urged, that if the black dust was so infectious, this distemper would make from year to year such progress, that in the end we should have nothing but burnt-grain. But we need not be apprehensive in this respect; and a year in which much corn is infected, succeeds one in which scarcely any burnt-grain was to be met with. Scarcely any was to be found in the crops of 1754, 1760, and 1761.

In reflecting on this objection, which has some weight, I think I have found an answer to it in M. Tillet's observations, which is, that hard winters, past all doubt killing the distempered plants, stop its progress.

It may also be said, that if this distemper is only caused by the infectious dust, how can it at first get footing in a province that was before unacquainted with it?

It is readily allowed that this distemper may be attributed to other causes besides the black dust: but M. Tillet's experiments incontestably prove this dust to be contagious: and his researches supply us with the means of lessening considerably, if not entirely extirpating this distemper: thus we may have larger crops, better bread, and corn more proper for keeping. What a satisfaction must it be to a man to have made a discovery so useful to his fellow-creatures, whose chief food is the several sorts of grain! We shall soon see whether habit, supineness, and ill-judged economy in the farmers, will not prevent them from reaping any benefit from M. Tillet's labours, who yet proposes to them simple and cheap methods of attaining an end which to them ought to be of infinite consequence. *Du Hamel's Elements d' Agriculture, vol. I. p. 134.*

Mr. Young, in vol. III. of his *Annals of Agriculture*, has inserted a letter from a correspondent, who says, "I beat down some hedges to throw three fields into one, and consequently ploughed across the old grass borders. The whole field was sown with wheat at Michaelmas. There was very little burnt wheat in any part of the crop, except on those old borders, and there a great deal. It seems that the cause of the distemper can only be discovered by making many observations. I simply state a fact, and leave others to reason upon it." Mr. Young further says, "A friend of mine, who was remarkably attentive to the distempers of corn, conceived that the smut was owing to a damage in the root of the plant. Indeed other experienced farmers classed burnt wheat as a species of smut: now, if the cause is to be looked for in the root, the foregoing observation is exceedingly in point, for an old grass border would almost to a certainty abound with the red worm, which eating the roots of the wheat, would destroy some, and damage other plants, and might consequently occasion the black ears. I may remark, that Mr. Varlo, in his *System of Husbandry*, assigns the smut to worms, and gives various instances strongly proving it."

BUR-TREE, a name given in some counties to the elder-tree.

BUSHEL, a measure of capacity for dry things, as grain, fruits, pulse, &c. containing four pecks, or eight gallons, or sixteen quarts.

A bushel, according to a statute made in the twelfth year of Henry VIII. is to contain 2,178 cubic inches, or eight gallons of wheat; the gallon of wheat to weigh eight pounds troy-weight. Mr. Ray tells us, that a bushel in Warwickshire is equal to two strikes, or two bushels, statute, or Winchester measure.

The French bushel consists of four quarters, and the quarter of four litrons, each containing thirty-six cubic inches. Consequently the bushel contains 576 French cubic inches, which, according to Mr. Greaves's calculation, is nearly equal to 615 English inches. The French bushel therefore is to the English bushel, as 615 is to 2,171. That is, the French bushel contains one peck, a quart, and two

two cubic inches nearly. It must however be observed, that the French bushel for oats is double that of any other grain.

BUTCHER'S-BROOM, or kneec-holly, the name of a plant common in woods in divers parts of England.

BUTTER. Mr. Young in his *Annals of Agriculture*, vol. XIV. has given a treatise on butter and milk, and on the traffick of salt butter, translated from the *Memoirs of the Royal Society of Agriculture in the generality of Rouen in Normandy*; which, as it has been highly approved, we shall here insert:

"The trade with foreign markets for butter to supply the great towns, and to export to our colonies abroad, being very considerable in France, it is natural to wish, as much as possible, to contribute towards bringing this article to perfection in this kingdom; and as Normandy, from being in possession of very good pasture land, on which vast numbers of milch cows are maintained, is capable of producing a great quantity of excellent butter, it has appeared essential to us to treat on the subject.

All the people of Normandy know the defects found in their butter, but few of them are sensible that these defects are much less to be imputed to the quality of the milk, than to the management of the dairy. One district only has acquired this knowledge, and none of the others have profited from its example, during the many years it has enjoyed this advantage.

By following the method observed in the district of Bray, which I am now about to describe, the butter would be delicately sweet and good throughout the year, and would become an interesting article of domestic concern, because it would then be proper for salting, and in a state for keeping during whole years; and by this method obtain a preference in the sale of it, to all other butter differently made, which would be a saving to the kingdom of considerable sums of money now paid to foreigners, who supply us when our ports are open, with a great quantity of very indifferent butter.

OBSERVATIONS made at MERVAL on the METHOD of making BUTTER in the DISTRICT of BRAY:

The milk is deposited in vaulted, deep, cool cellars, nearly such as are constructed for the keeping of wine, the temperature of which, both in winter and summer, is from about eight to ten degrees, by M. de Reaumur's thermometer; some are paved with common square earthen tiles, and others with common bricks. When they are apprehensive of the heat penetrating into these cellars, the air holes are stopped, during the heat of the day, with a wisp of straw; the same method is observed to prevent the cold penetrating during a frost. The door as well as the air holes should be placed so as to open either to the north or the west; the entrance is frequently made through an apartment of the house, in which a fire is never lighted.

Cleanliness is thought so essentially necessary in these cellars, that they banish from them all wooden utensils, planks, &c. lest they in time should rot, and occasion a smell in the place. Not the smallest appearance of dirt is to be seen, either on the roof, or the sides of the air holes, or on the floor; to preserve which cleanliness, the bricks are frequently washed; no person approaches these dairies but in wooden shoes, which are always taken off and left at the door by the people who have the care of the dairy, and whose business it is to put upon you the shoes proper for entering the cellar; the least smell then, excepting that of fresh milk, would be detrimental to the butter, and looked upon as a want of attention in the servants. Cleanliness is held so essential to the perfection of butter, that in Saxony and in Bavaria, when the cows have lain in a stable, they rub and wash them before they are milked.

The vessels into which the milk is poured are earthen pans, scalded with boiling water, to cleanse them from the stale milk, which may have been incorporated into the earthen ware of which they are made. This rancid milk is an invincible sort of leavin, but well known, from repeated experience, to be destructive of the new milk by its acidity. The size of the milk-pans is fifteen inches wide at top, six inches at bottom, and six inches deep. These dimensions are taken on the outside of the pans; a greater depth would be hurtful, and more width would be inconvenient. Each pan contains four quarts of milk: they are placed on the well-cleaned bricks of the cellar-floor, whose coolness prevents the milk from curdling; to answer which end, and to hinder it from turning sour in summer, before the cream is

taken off, and freezing in winter, so as to render it too difficult to procure butter from cream so frozen, are the great objects to which every thing tends in these cellars. The milk is carried in wooden pails, or in earthen vessels, into which it is milked, to the dairy, from whence all brass utensils are banished, as dangerous: it is left to remain in these pails for about an hour, until the froth and the natural warmth of the milk have subsided, then it is poured through a sieve, to prevent hairs or any other filth from entering into the pans, in which it is set. The pans, thus filled and placed on the bricks, are left for four and twenty hours, and often for a less time; they are then skimmed; to delay the skimming a longer time would be wrong, for the cream would lose its sweetness and become thick, and the milk from whence it is taken be curdled and sour, which is absolutely against the goodness of the butter. In skimming it they proceed as follows:

The dairy-maid lifts the pan gently from the floor, and places the spout of it into a large pitcher made for holding eight or ten quarts, and with the end of her finger raises the cream just at the spout, so as to let the milk from underneath flow into the pitcher through that opening, by which means the cream remains by itself in the pan: all the pans set at the same time; the cream is then collected into other pitchers to be churned.

If the season requires the cows to be milked three times a day, the same process as above is likewise observed thrice in that space of time, when the milk has been deposited for four-and-twenty hours in the pans.

It is to be observed, that from the milk-pans being only six inches deep, the particles of butter rise more speedily to the surface, and are sooner formed in the course of eighteen or twenty hours, more especially when the temperature of the air in the cellar prevents the milk from being coagulated.

If the weather is tempestuous, very sultry, and threatens a storm of thunder, the milk is apt to curdle and become sour, which should be prevented. The dairy-woman, as soon as the most distant thunder is heard, hastens therefore to the cellar, has the air-holes stopped, cools the bricks by sprinkling them with water, and skins those pans on which the cream has begun to set, for on such extraordinary occasions the cream usually appears in twelve hours time.

By pouring off the milk from the cream, in the space of four-and-twenty hours after it is set, the butter-milk in the cream cannot have acquired any acidity, since the skim-milk remains perfectly sweet, and is of so thin a fluid that no part of it rests with the cream to turn it sour, during the four or five days it is kept in the cellar before it be churned.

Those who are acquainted with the general custom of the Higher and Lower Normandy, in the management of their dairies, will easily judge that the earthen pans, large enough to hold from nine to ten quarts, usually made use of there, cannot be so cool as those employed in the district of Bray; and that the custom of pouring the milk still warm into them must tend to heaten, instead of cooling, and prevent the particles of butter in the milk from rising soon enough to skim the cream before the milk becomes sour; that likewise the custom of exposing these great pans to extreme cold and great heat, without paying any attention either to the smell or to the cleanliness of the place, must militate still more strongly against the goodness of the butter, and that the suffering the milk to curdle, and grow sour before it be skimmed, by leaving it in the pans for five, six, and often eight days, are methods of destroying both the milk and the cream so effectually as not to derive any advantage from them.

It is a known fact, that acids destroy visibly greasy particles, by giving them either the consistency of soap, or reducing them to water; it is likewise acknowledged in the district of Bray, that the cream taken off, when light, new, and sweet, from milk which still retains its sweetness, produces a greater quantity of butter in proportion, than when it is suffered to remain and grow stale, or curdled sour milk; it not only lessens the quantity, but is likewise prejudicial to the quality, by being greasy, not keeping fresh, and totally unfit for salting: the principal object of our enquiries.

We are well acquainted with several districts of this province, in which the butter made, is good, and delicately sweet in autumn, and at the beginning of spring; but it becomes greasy and bad in summer, because the temperate coolness of the spring and autumn naturally operates nearly in the same manner as is effected on the milk, by industry, the whole year, in the district of Bray: on the return of the

the summer, the founes of the milk spoils the butter, makes it not worth purchasing, notwithstanding the excellence of the feed; it is from hence to be presumed, that if a better method were adopted, they would not be deprived of the advantages which might reasonably be expected from that fine season, when the pastures become infinitely better and more luxuriant. We know a farm, whose principal return was in butter, and which formerly, when it was occupied by intelligent people, produced butter of a superior quality, and sold as such even in the district of Bray; this farm having passed into other hands, less intelligent on this article, and the farmer's wife having imbibed all the prejudices she had been taught in the district of Caux, and adhering strictly to them during the nine years of their lease, the butter from thence was sold during that period on the footing of the very worst, and for a third part less than that of their neighbours; but neither this loss, nor all the remonstrances of the proprietor of the farm, could prevail on her to change her method of proceeding. For the last eight years this same farm has been in the possession of a skilful and laborious man, who follows the best plan, in consequence of which, his butter immediately regained its credit, and is now ranked among the best sorts in the market of Gournay. It is from this last-mentioned farmer that we have taken the account here given of the management of the dairy. This anecdote proves the advantage to be gained by judicious management, independently of the soil, however good that may be in itself.

All skim-milk is sent out of the cellar, lest it should prove hurtful to the other milk, but the cream is kept there, four, five, and sometimes eight days, before it is churned, notwithstanding which, they acknowledge, that the less time it is kept, the nearer the butter is to perfection.

In large farms, where the cream is in too considerable quantities to be confined to the common churn, they make use of a machine called a *serene* or churn; it is a barrel three feet long, by two and a half round in the middle, measuring it on the outside: at each end is placed an handle fastened on by means of an iron cross which supports them; these handles rest upon a wooden tressel made for the purpose, of a convenient height, for the women to turn with ease the churn. The iron crosses on which the handles rest, and which are fastened at each end of the barrel, serve to prevent the being obliged to pass an axis through the inside where iron would be improper: these handles are made three feet long, to allow of two or three people working together, when the quantity of butter in the churn requires so much assistance.

The inside of the barrel is furnished with two small shelves, each four inches high, fastened to the staves of the barrel, representing the interior view of the machine; but in the opposite side, the shelf reaches from one end to the other of the barrel, being fastened to the staves by the ends. These shelves are made sloping at the extremities, that the fluid may with more facility run off the slope when the churn turns round.

An hundred pounds of butter may be made at a time in a churn of the above dimensions: there are some larger, as well as some of a smaller size: it matters not in fact what implements are used in the making of butter, since they cannot influence its quality, provided the proper attention is paid without interruption to the business; the churn is used to accelerate the work by making a great quantity at a time; any other machine that would answer the same end, might as well be employed for the purpose.

The cream being poured into the churn, the opening, which ought to be at least six inches wide to be convenient, is then closed with a bung wrapped round with cloth dipped in lye, as will be mentioned hereafter; over the bung they pass an iron peg, which goes into two strong iron staples fastened to the barrel, so as to stop it closely: four or six people then turn the barrel, until the butter is made, which is done in an hour's time in summer, but lasts for several hours in winter. This work costs but little, for the farmers' servants make the poor women in the village assist them, for the trifling recompence of the butter-milk.

It is easy to conceive that the cream must soon be churned by the action of turning the churn as it falls, each time twice, from one of the small shelves to the other; the butter is known to be made when it falls in lumps: the butter-milk is then poured from it through a hole, that had been stopped with a wooden bung of about an inch in diameter; by this same hole, they pour through a tunnel a pail of cold water, and having bunged it up again, they continue to

turn the churn in order to wash and cool the butter; this work is repeated three times, if they wish to have the butter well cleansed, and it is suffered to remain some hours in the last water to cool, and to increase its hardness, when the heat of the weather makes it requisite.

The butter being sufficiently cleansed, they open the large bung hole, from whence with the hand they draw the butter out in balls, from two to three pounds, which they form into lumps of different weights, even as far as to fifty pounds, by heaping it up on linen cloths washed in lye for the purpose. The largest lumps are the most valuable, because they are kept thereby better for exportation; they decorate this merchandise with small pieces of wood carved, and mark it with wooden spoons.

The natural whiteness of the butter during the winter months is unpleasant to the seller, to the buyer, and still more disagreeable to the consumer; a method, however, has been found out, for giving it the same yellow colour it has in summer, without making any change in the quality of the butter, or giving it the least taste.

A great quantity of the leaves of the marigold flower are gathered, either of the double or single sort; they are both equally good when fresh plucked; as they pick them, they throw the flowers into a stone jar, which is covered up, and deposited in the milk-cellar, where, after standing some months, these leaves become a thick liquor that retains all the colour of the marigold: with this liquor they colour their butter during the winter, by putting a small quantity of it with the cream, when they fill the churn; custom teaches the quantity necessary to be used of this liquor; it must depend much on the degree of colour you wish to give your butter; it remains fixed, for the butter never loses it; the flowers of marigold have not any unwholesome quality in them being considered as cordials; and sudorifics, the very small quantity used in this process cannot have any sensible effect.

On the cleanliness necessary to be observed in the making of butter.

Butter sticks not only to every thing it touches, which is not exactly clean, but it likewise does so, to whatever has been well washed, and even scalded with boiling water, unless the cloths, utensils, &c. have been washed in lye, made either of fine ashes or of green nettles so mashed as not to sting: this last is most frequently used, and each time any vessel, cloth, and other utensil has been employed about the milk, cream, or butter, they are washed in this lye, before the using of them again; nay even the mistress of the dairy, who commonly has the charge of handling the butter in taking it out of the churn, to make into lumps, is obliged to rub her hands and arms with the lye, to prevent the butter from sticking to them.

The use made of the skim, and butter-milk.

The milk that remains after yielding the butter, consists first of butter-milk which feeds the poor people, and is made into soup, for the labourers, and women servants of the farm, and serves also to moisten the bran which is given to the poultry in the yard, &c.

Secondly, the skim-milk.—This is given to nourish the calves, is made warm, and mixed with an equal quantity of water, but the milk being deprived of its rich particles, occasions amongst the calves a languid disorder, of which great numbers formerly died; but a remedy is now found out for it, by restoring the sick calves to their mothers, who by suckling, soon bring them back to their former vigour; this is, however, an expensive remedy, because it deprives the farmer of the butter he would otherwise reap from the milk.

It is said, that by mixing the skim-milk, with an equal quantity of water in which turneps, parsnips, and such like sweet and nourishing roots are boiled, prevents the disorder, and fattens the calves, the juice of these plants supplying in some measure the want of the particles of butter taken off with the cream.

We think this experiment may be very safely tried: but it is necessary to inform the country people, who in general make use indiscriminately of copper vessels for heating the skim-milk given to their calves, that this milk being disposed to turn sour, draws from the copper a corrosive quality, likely to hurt the animal and even to prove fatal to it. It is much safer to use earthen vessels or iron boilers, from which no inconvenience can arise. With regard to the remainder of the skim-milk not used for the calves, it is turned

ed as soon as possible into curds, before it becomes sour, and then made into common cheese for the servants of the farm, and to sell to the poor people: moreover the whey from the cheese is mixed with whatever skim-milk is left, and serves to feed the hogs.

On the salting of butter.

The object we have in view is to render the butter proper for salting, and by such means to introduce it as an article of commerce, not only in the interior of the kingdom, but to make it such with the other countries of Europe, and to extend this branch of trade beyond the Tropic.

The process we have explained in the foregoing pages, gives all the necessary qualities to be desired for the butter being kept; but to ensure the keeping, it must be properly salted; to accomplish which, much depends on the quality and quantity of salt used, and the vessels into which it is put after being salted, and on some other circumstances.

The farmers not being accustomed to sell their butter ready salted, carry it to the markets of those towns where the consumption is greatest; there each person provides himself with the quantity of fresh butter he wants; the buyer distinguishes the good qualities of that made in the district of Bray (whose management of the dairy I have explained) from what is made in the district of Caux; he gives a good price for the first, and rejects the last, which is consumed fresh in the interior parts of the country. The butter should be salted, as soon as possible; all delay being prejudicial to it. They wash it until the water no longer appears milky; the grey salt, such as is distributed by the Gabelle, ought to be used, and not white salt, which is reputed bad for all sorts of salt provisions: the grey salt is put into an oven to dry; it is then pounded; the butter being washed and spread out, an ounce of this dried and pounded salt is sprinkled on each pound of butter, which is then worked up until it is well incorporated, and put into stone jars of different forms; the jars having been first scalded with boiling water, in order to be cleansed from any remains of the former butter that may have insinuated itself into the pores of the stone; after the scalding, they are scoured with lye, as mentioned before in speaking of the utensils, &c. employed about the butter.

These jars contain from twenty to thirty pounds; the salted butter is pressed down in them, and filled within two inches of the brim: it is then left in that state seven or eight days, during which period it diminishes, and shrinks, so as to leave a space between that and the sides of the jar, into which the air might gain admittance, and would spoil the butter if it was left in that situation; to prevent this accident, they prepare a brine of common salt and water, made strong enough to bear an egg, for it would be risking much to make it weaker; the brine being left to settle, is then drawn off clear, and poured on the butter in such a manner as to fill up the space between that and the jar, and to dispel the air from it; to effect which the brine is poured in by degrees, a little at a time, and the jar gently moved. They augment the quantity, until it rises an inch above the butter, which is thus secured on all sides from the air, unless it should float in the brine, in which case the lump must be increased, so as to keep it by its weight down, and preserve every part of it from spoiling by being exposed to the air.

These are the methods observed in salting of the butter we keep throughout the year at Rouen; it is used in the first families there, and employed with success in the preparations made for the most delicate tables.

All butter salted in this manner, and kept in stone jars, with a sufficient quantity of brine, would have the same advantage with this of the district of Bray, of which we are speaking, because the principal cause of its keeping proceeds from the cleansing it entirely of all the acidity, from the sour milk, and the potting it in good stone jars, well scalded and scoured in lye, (as we have already recommended) that cannot communicate any bad quality to the butter.

When this merchandise is to be sent to a distance, the brine cannot be preserved during the journey; in order therefore to replace it, salt is laid an inch thick over the top of the butter, which answers very well for a short space of time, so that well-made butter sent, when salted, from divers districts of Normandy to Paris, or into the neighbouring provinces, would be very good although it arrived without the brine.

The case is not the same with butter destined for shipping; it is difficult to carry a great quantity of it in jars because of their being brittle; from hence comes the method of putting it into kegs of wood, but whether it is put in wooden or earthen vessels, it is equally impossible to keep it covered with its brine in the hold of a ship destined to sail beyond the Tropic.

To remedy these inconveniences, particular attention ought to be paid in preparing the wooden kegs, to preserve them from the fermentation of which they are so susceptible, when exceedingly heated in the hold of the ship, as for the sap to give and change the quality of the butter, so as to make it greasy in spite of the salt. The same fermentation in a little time shrinks the staves of the keg, the brine then runs out, and the butter spoils immediately; a remedy for this may possibly be found, and it would, without doubt prove a most advantageous discovery, as it would probably tend to the preservation of all the provisions embarked on the sea, upon which depends, in a great measure, the success of navigation, and the health of the navigators. The bad quality of these provisions has been more destructive of mankind than all the shipwrecks and battles ever were: but this subject demands reflections and experiments very foreign to agriculture.

To preserve the butter during the navigation, it must be pressed down into pots, covered with salt, and guarded from any air coming to it; a vessel of a conical form, or one quite a cone, from whence it might easily be slipped out in a lump, after it has contracted itself into that form, would be such as I should prefer; for the whole lump being then done over with salt, and forced down again into the pot, might keep without brine, because the cone being placed on its point downwards, the butter would sink more and more into it, from the heat of the ship's hold, by which means the only void space would be on the top, which would be covered with salt: tubs made of wood, in like form, would answer the same end, provided the fermentation of the wood they are made of could be prevented.

In general, to judge from the nature of the soil, and from the animals fattened there, the greatest part of the pasture land in Normandy appears preferable to that in the district of Bray. If, by means of some encouragement, the method of making good butter could be introduced into those districts where it is now so ill made, the salt butter that is brought from Isigny, and from some of the other districts of Normandy, would not be left for the use of the common people only. It is to be presumed that such butter would then become the basis of a commerce, most lucrative to the possessors of extensive pasture grounds, since at this present time there is not a milch cow which does not bring into its owner a clear yearly profit of fifty livres. Besides the advantage to be gained from the rise in the value of butter, and in the fattening of calves and of the cows, it is well known that the feeding of bullocks is not nearly so profitable to the grazier as the keeping of milch cows would be. This advantage would last until the quantity of butter was in proportion to the demand made for it; and let what would happen afterwards, it is a branch of trade that must always be an interesting article of agriculture, by putting us in a situation not to employ any longer foreign aid for our supply."

The great demand for this treatise, and the general wish to follow the method we have here explained, makes us hope that in time it will prove of much utility to the farmer and the labourer, as well as the proprietor of farms. See the article DAIRY.

BUTTER-BUR, or *pestilent wort*, the name of a weed resembling colt's-foot in many respects; but the flowers are purple, and grow in a thirfe. The leaves come out after the flowers decay; and are like those of colt's-foot in shape; but three or four times as big. It infests meadows and pasture grounds, where it proves a very troublesome weed. See the article COLT'S-FOOT.

BUTTER-FLY, the name of a numerous, and well known-class of insects.

M. Duhamel has frequently noticed and made drawings of a species of small insects, some of a bright red, and others black, found in great numbers in the ears of wheat. He suspected that they fed on a sweetish juice which is in the ear whilst green: and M. Tillet, who was immediately of opinion that they might do considerable damage to the grain, followed them very arduously in all their metamorphoses, of which he has given a full account in a memoir that

that gained the prize of the academy of Bourdeaux for the year 1755.

The inhabitants of a considerable part of the province of Angoumois have, for thirty years past, sustained an hitherto irreparable loss, by an insect which begins to devour their corn, even in the ear, before it is reaped. This scourge deprives them annually of their most promising crops. It appeared at first only in a few hamlets, but soon made a rapid progress, and has now spread to the lands of upwards of two hundred parishes. Famine and the most fatal epidemic diseases have often taken rise from less beginnings. Messieurs Duhamel and Tillet were deputed by the Academy of Sciences at Paris, of which they were members, to enquire into the nature of this insect, and the means of preventing and curing that dreadful calamity occasioned thereby. They jointly published a small treatise on this subject, from whence we shall extract the following remarks so much the more readily, as their means of prevention and cure in this particular case may be equally applicable to the injuries done to corn by insects in general.

This insect is most generally known as a butterfly, very much like the moth which preys upon woollen cloths, or the false moth, which is found in great quantities in the granaries of all countries, and which feeds on corn. M. de Réaumur, whose accurate inquiries into nature nothing could escape, has minutely described both these insects.

The butterflies which proceed from the wheat caterpillar are often smaller than the false moth. Some of them are however, larger, and longer shaped: but, that excepted, they are much like them: they are likewise of the class of four-winged phalænæ or night butterflies: their wings are long in proportion to their breadth, which is almost equal at the upper and the lower end. The colour of the upper wings varies; being sometimes of a light, and sometimes a darkish greybrown, but always shining when exposed to the sun. The position of these wings, of which the edges are close set with long hairs, is horizontal when the insect first settles after having flown; but soon after those edges incline downward. Its head (Plate V. fig. 24, 25, 26.) is furnished with two antennæ (fig. 27.) the joints of which, nicely fitted into each other, lessen gradually up to the point. Its eyes are almost as large as those of the false moth. Between the antennæ are two beards, (fig. 28.) which proceed from the lower part of the head, and rise up above it; and likewise between the antennæ is a tuft of hairs, which turn up backward.

These insects do not take any food while they are in the state of butterflies, as will be proved by several experiments; nor do, or indeed can they, prey upon and destroy corn during that time, as is the general, but mistaken opinion in Angoumois; for they have not even organs capable of doing it the least injury. Their only function then is to procreate their species.

The males of these butterflies seem, in general, to be larger than the females: but they cannot well be distinguished with certainty, unless they are seen coupled together, which, according to the very nice and careful observations of Mess. Duhamel and Tillet, never is but in the night-time, or in a dark place. Their copulation then is like that of the silk-worm butterfly: the body of the male and that of the female then form one straight line; their heads are turned different ways; the ends of their wings rest upon each other; and their conjunction lasts several hours. The abovementioned gentlemen, with many other witnesses, saw great numbers of them in this situation, both upon heaps of corn in granaries, and upon ears of corn in the field. They caught two of them in the act of copulation, and put them into a glass covered over, where they then separated, but were found joined together again next day, in the evening.

As soon as the female is impregnated, she lays her eggs in great numbers. Messieurs Duhamel and Tillet put a male and female, coupled, into a glass vessel, and, watching them carefully, saw the female, soon after her separation from the male, deposit her eggs, sometimes on one spot and then on another, in heaps of 60, 80, or 90 together. These eggs are squirted out, as it were, commonly by three, four, or half a dozen, and sometimes thirty at once; and at each squirt of this kind the female changes her situation. Those which were inclosed in glasses cast some of their eggs upon a few grains of corn deposited at the bottom of those glasses, and, finding themselves cramped there, laid others on the sides of the vessel. The eggs are accompanied with a viscous

matter, which makes them stick to the places they are laid in; and this cohesion soon becomes very strong.

These eggs, as may easily be imagined from the size of the mother and the great number which she lays, are so extremely small that one of them would drop through a hole made in a bit of paper with the point of the finest needle. When examined by a microscope, they look, as in fig. 4. not unlike the nymphs commonly called ants eggs. They are streaked length-wise, and appear rough or curdled. When first laid, they are white; and afterwards they become red, as if tinged with carmine; owing to the colour of the caterpillar within the egg, of which the shell is very thin and transparent, as is evident after the caterpillar has left it.

By means of the thinness and transparency of this covering, the caterpillar may be seen within the egg, as at *b*, fig. 5. At first, it is bent, as in fig. 6: some time after, it wriggles itself into the situation represented in fig. 7; and then makes a hole through the end of the egg, and comes out there, as in a fig. 8. This opening remains at the end of the empty eggs, as at *c*, in fig. 5.

It is with great difficulty that the caterpillar gets its two legs out of the egg; but after he has extricated four or six of its legs, it soon draws out the rest of its body. At its first issuing from the egg, this caterpillar looks like a bit of hair about a quarter of a fifth part of an inch long.

These caterpillars generally come out of their eggs on the sixth or seventh day after they have been laid. Some say they have seen them hatch at the end of four days. The temperature of the air will undoubtedly influence this variation. They are red, as was said before, whilst in the egg; but that colour goes off by degrees after they are hatched, and they soon become almost white.

The female butterflies which are upon the ears of corn in a field, endeavour to place themselves in such manner as to lay their eggs close to the place where the grain is fastened to the stalk. Fig. 1. represents some of them at *a*, in the attitude of thus laying; in which case their eggs are deposited near the bottom of the grains, toward the stalk: but it often happens that, in their hurry to lay, they scatter their eggs in other places, as represented upon the husks in fig. 2 and 3.

As soon as the caterpillars are hatched, they set about making their way into the grain, in order to feed upon its flour. If the eggs have been laid in the granary, after harvest, and upon the grains themselves, they generally creep into the furrow *a* of the wheat (fig. 9. and 10), and there weave a slight web *b, b*. They then tear a hole in the skin or rind, range round them the particles of the bran thus separated, and wriggle themselves into the mealy substance which is to be their food. The hole through which the caterpillar entered can then no longer be perceived, but by a little heap of bran which lies upon it, as in fig. 11. This small quantity of pulverised bran, which is a sure sign that a young caterpillar has got into the grain, may easily escape the notice of those who have not observed it before; but when once known, it is easily distinguished.

When the eggs are hatched upon the ears, in the field, the young caterpillars soon find means to glide in between the chaff and the grain, and in that situation they pierce the latter, as was said before, generally in the furrow, but sometimes at the pointed end, which is a little hairy.

To set this in a yet clearer light, it is to be observed, that, in most kinds of wheat, three grains of corn adhere, or are fastened, at the same height, to the spike or stalk which traverses the ear, as at *b, b, b*, fig. 1. in such manner as to form a sort of triangle, or flower-de-luce. Each grain is covered with three concave coats or husks, the smallest and thickest of which is represented by fig. 2. and 3: their inner husk is covered by a broader, but thinner; and this grain is covered by a still larger, from which arises the beard, when there is one. Over all these there frequently is a fourth tegument, or very thin membrane, more or less wide. All these husks lap over each other like the scales of a fish, and envelop the grain. The end *e* (fig. 9.) is uppermost, and the end *f* rests upon its supporter. The germ is at the end *f*; and the extremity *e* is covered with a hairy down.

The young caterpillar finds means to creep under all these scale-like coverings, and to get at the grain, which, after having wove a slight web of only a few fine threads, either to cover itself, or to hold by, it attacks, sometimes at the upper end *e* (fig. 9), which is very soft in green corn; and sometimes, if it has crept in at the lower end, it lodges in

in the longitudinal furrow of the corn, and there begins to mine, in the manner before related.

As the husks of barley are harder, and stick much closer to the grain, than those of wheat, it is almost always at the point *d* (fig. 12.) that these caterpillars slip into that corn, by means of a small opening generally perceptible in that part.

To conceive how these small caterpillars, which are hardly able to pierce the rind or bran of wheat, can glide into barley by means of the opening before mentioned, it is necessary to consider the organization of this grain. It is formed of two lobes *c, c*, fig. 12. which are partly separated by a furrow in its middle, and partly covered by a tegument *a a*, which fits exactly close and adheres strongly to the lobes *c c*, and terminates in a long awn or beard *b*, of which only part is represented in this drawing. The two lobes *c c* are again covered with their proper tegument, which ends in two small appendices at *d*. Here generally is a chasm or opening, through which the caterpillar penetrates to the mealy substance.

To trace this caterpillar in its further progress after it had crept in at this opening, and consequently disappeared, Messieurs du Hamel and Tillet tore off the appendices *d*, fig. 13. and found, that after having wove a slender web, it had immediately begun to attack the lobes of the grain of barley, as was evident from the bran around it. After it had made its way intirely into the grain, and was buried there, they saw nothing but the little heap of bran it had thrown up, over the hole through which it entered.

Notwithstanding the industry of this insect, it seems highly probable that the young ones meet with great difficulties in their attempts to get into the grain; since very many of them die before they can effect a lodgment in the mealy substance. This number is so great that it might induce one to wonder how such quantities of corn can be destroyed by these caterpillars, if one did not consider the vast fecundity of the female butterflies. But the sequel of this account will shew, that if prodigious numbers of them did not perish, it would hardly be possible to save a single grain of any kind of corn.

The people of Angoumois were strongly of opinion, that the mischief occasioned by this insect was peculiar to the corn of their country, and that what was brought to them from other places always escaped unhurt. To clear up this point, Mess. Duhamel and Tillet put into different glasses wheat of the growth of other provinces, and with grains, in each glass, some of these butterflies actually coupled. They soon saw the female lay her eggs upon these grains, and afterwards beheld the caterpillars hatch and make their way into the grains. Their farther observations proved, that the principal cause of the spreading of this evil is, that the insect itself, which multiplies exceedingly, is conveyed to other parts with the corn in which it is inclosed.

The caterpillar inclosed in a grain of corn preys upon the mealy substance of that grain, till it has eaten it all; by which time the insect has attained its full growth. Whenever a grain was opened (fig. 19.) in which the caterpillar was not full grown, a deal of flour yet remained; but when this insect was full grown, there remained only the skin, or bran, so destitute of flour, as not even to discolour clear water. Hogs, though very greedy creatures, and fond of bran, would not touch these hulls when given to them unmixed; but they eat them readily enough when mixed with other food.

M. de Réaumur suspects that when these caterpillars have consumed all the flour, they eat the excrements which they had voided whilst young. At least it is certain that, upon opening several grains in which the insect was young, a number of small white pellets, like eggs, was found near the caterpillar; and a half-grown caterpillar being taken out of a grain, and laid upon a piece of glass at the focus of a microscope, it was seen to void a quantity of excrement very white, smooth, and oval; and when the caterpillars were ready to be metamorphosed in the spring there remained only a very small portion of dark brown excrements, quite different from the white that were observed at first.

The length of the corn-caterpillar, when full grown, is very little more than the twelfth part of an inch; and its thickness is, at most, equal to half the circumference of the grain that contains it: its body is smooth and entirely white; it is thickest towards the head, in which one may perceive its mouth, two large eyes, and two kinds of horn: the head is a little browner than the rest of the body. This

caterpillar has sixteen legs, of which the eight intermediate and membranous are only small prominences, so minute as not to be distinguished even with the help of a microscope, unless the insect be laid upon its side.

Our authors make here the following digression, to shew the difference between this insect (fig. 23.) and the false moth (fig. 31.); it being the more important to distinguish them, as they are very much alike in many respects, and often blended together in the same granaries.

The false moth proceeds from a small caterpillar, the body of which is smooth and whitish. It has sixteen legs, does not lodge in the grains of corn, but contrives to fasten several of them together with a web which it spins, and with which it makes itself a dwelling-place like that of common caterpillars. This dwelling-place, or sheath, in which the caterpillar of the false moth usually abides, is generally in the middle of the little heap of grains which it has collected for its food, as in fig. 30: but what distinguishes it from the caterpillar of the true moth, it can quit this sheath at any time, to eat the grains around it, one after another. It generally attacks several grains at once, and always without order, eating sometimes of one, and sometimes of another, so that several are gnawn when not one is wholly consumed. When these insects are very numerous in a granary, all the grains upon the surface of the corn are linked together by a web, so as to form a crust which is sometimes three inches thick. This caterpillar turns into a chrysalis, or aurelia, in a grain which it has hollowed, or in the sheath of its web, and issues from thence, in the month of June, in the form of a butterfly. When a heap of corn is stirred in which there are many caterpillars of the species of this false-moth, those insects crawl up the walls: but they soon return to the heap, and, by the very next day, cover it all over with a new web.

The insect which desolates many parts of Angoumois is more sparing of the mealy substance of the corn, than the caterpillar of the false-moth; for the former seldom consumes more than the contents of a single grain. Nothing is more uncommon than for it to pass from one grain to another, even though it be immediately contiguous. It eats the flour in such manner that the skin or rind of the grain, which is entirely emptied, looks whole and sound: but the least pressure then easily reduces it to powder; and it rises up to the surface of water more or less quickly, according as the insect has left in it more or less flour.

As heat hastens the metamorphosis of the insect, it is not unusual to find, in very hot weather, some of these caterpillars transformed into aureliæ, before they have consumed the gross excrements before-mentioned, or even eaten all the mealy substance of the grain. In this case, the aureliæ are very small and produce only small butterflies. The same happens to other insects of this kind. Silk-worms eat but little when they are sickly, and, if that sickness continues, they are metamorphosed sooner than others which are healthy; but then their cocoons always are small. If a field caterpillar be shut up in a box before it has attained its full growth, it will, after having fasted some days, be converted into a small aurelia, from it will issue a butterfly smaller than others of the same species. In like manner, when one sees among the corn caterpillars some larger than others, it may reasonably be presumed that this difference proceeds from there having been a greater quantity of flour in the grains on which they fed, than in those which were the nourishment of smaller flies; or from their having been of a stronger constitution. It likewise appears that some of these caterpillars are so much more voracious than others, that the flour of one grain is not sufficient for them. M. Duhamel put several of them into a box of flour: they thrived there, and seemed to grow larger than in their common way of feeding in the grain.

In general, they are metamorphosed much sooner in summer and when the air is warm, than in winter, or in cold weather. It may likewise be observed, that the mealy substance of a grain is more completely consumed when the metamorphosis is slow, than when the contrary happens.

The sagacity of M. de Réaumur was requisite to discover a singular circumstance relative to the working of this insect, and of which Mess. Duhamel and Tillet have been witnesses. The caterpillar, exactly inclosed in its grain, foresees, or acts as if it knew, that, in its future state of butterfly, it will be deprived of the organs necessary to pierce through the rind of bran which forms its prison. However, whether it has or has not that foresight, the fact is, that the caterpillar, before it is changed into an aurelia, makes in

this covering of bran a small trap *a* (fig. 21.) which remains shut. Messrs. Duhamel and Tillet could not easily discover it at first; but after some search, a little spot whiter than the rest, about as big as the head of a small pin, and somewhat prominent, shewed them where it was. They then, upon lifting up this trap (fig. 22.) with the point of a fine needle, could see the chrysalis in the inside of the grain, and could also, sometimes, close the trap again so exactly, as not to leave the least appearance of a hole.

When the caterpillar has attained its full growth, and formed its trap, or outlet, it weaves a cocoon, and is afterwards metamorphosed, within the grain, into an aurelia, (fig. 20.) which seems at first to be divided by ringlets (fig. 14.); but when the butterfly is formed within the aurelia, its wings may be discerned through the membranes which cover it, as in fig. 15, 16, 17, 18. The above-mentioned accurate observers opened some of these aureliæ in an advanced state, and took out of each of them a butterfly greatly rumpled and benumbed. When one of these caterpillars first issues out of an egg, and when a full grown one is taken out of a grain of corn, the body of each, then seemingly more at ease, dilates, so that one can hardly conceive how it could be contained in so small a space as that from whence it came. The case is different when one opens a grain in which there is an aurelia; for it is easily seen that this occupies little more than half of the inner capacity of the grain which incloses it, and that the caterpillar, in forming a cocoon, has divided the grain into two spaces or cells, in the largest of which, being somewhat more than half, the aurelia is lodged, whilst one sees in the other nothing but its excrements. The aureliæ are therefore small in comparison to the caterpillars that were metamorphosed into them. Nor is it less surprising how a butterfly just come out of the aurelia could be contained within that covering.

The butterfly, being entirely formed in the aurelia, breaks the skin of it at the end, opens with its head the little trap which the caterpillar had made on the outside of the grain, and comes out at the little hole which was covered and shut by that trap. The mealy substance of the grain has, by that time, been so far consumed, and the outside husk or bran rendered thereby so light, that the butterfly, after having disentangled its wings, takes its flight, and sometimes carries away the empty hull. As soon as the butterflies are out of the grains which contained them, they couple, and the females lay their eggs in the manner before related. Such is the circle of their life.

This insect, like all others of the same species, remains, as was said before, a longer or shorter time in its different states, according as the temperature of the air is more or less favourable to its several changes. It is known that an aurelia of a caterpillar, which generally produces a butterfly in eight days, will continue three months in the state of an aurelia, if it be put into an ice-house, and that the butterfly does not, in that case, come out, till after it has been removed into a much warmer air. For this reason one cannot fix precisely the time within which the caterpillars are transformed into aureliæ, nor how long they remain in this state: it can only be said, that they come out of their eggs very soon when the air is warm, and that they sometimes continue long in the state of caterpillars, as well as in that of aurelia, if the weather be cold: to which may be added, that both caterpillars and aureliæ, of different sizes, are seen in the field in warm weather; that butterflies are seen to issue out of corn from harvest till the end of September; and that caterpillars of various sizes may be found in the infected grains, during the whole winter.

"In the middle of May 1761," continue Messieurs Duhamel and Tillet in their account of this insect, "when we arrived at la Rochefoucault, there were many caterpillars in the corn, very few aureliæ, and not many butterflies. The weather was then very dry, and the nights were cold. On the 21st, the wind changed to the west; and in a few days after it began to rain, and continued so to do till the end of the month. During this time the thermometer was at from 13 to 14 degrees of Reaumur, or from 56 to 58 of Fahrenheit.

"In the beginning of June, we found in the grains of corn many more aureliæ than caterpillars; and on the 5th of that month, the air being then become pretty warm, we saw numbers of butterflies. By the 15th, they were increased so prodigiously in the closets where we made our experiments, that they perfectly darkened the day, and flew into our mouths if we opened them. We could then find but very few caterpillars, except in the corn which had been laid in cool places. We believe that the duration of the

life of the butterflies is, in general, a fortnight or three weeks; though some of them have lived a month in our glass vessels. The sequel will shew that the whole circle of the life of this insect may be completed in less than fifty days, when the air is warm.

"The coming out of the butterflies is generally denoted by a great heat in the heaps of corn, or in the sheaves, according as the grain is laid up in one or other. It was such as to make the liquor in M. de Reaumur's thermometer rise to 25 and 30 degrees (from 62 to 71 of Fahrenheit) when the outer air was at 15, (35 and a half of Fahrenheit). This heat certainly accelerates the hatching of the insects; for prodigious multitudes of butterflies issue out of the heated corn in a few days after the ferment has taken place.

"The coolness of autumn interrupts their propagation; and no more butterflies appear from that time, till the warmth of spring begins to be felt. But, may not the heat, which favours the multiplication of these insects, be produced by the creatures themselves when assembled in vast numbers? This is very possible: for it is well known that there is a considerable warmth in well stocked bee-hives; and that corn greatly infested with weevils or moths, is also very hot. We shall hereafter have occasion to observe that no sensible heat is perceived in heaps of grain in which there are but few caterpillars, and that the heat abates after most of the caterpillars have been changed into butterflies. It sometimes happens that, through some cause or other, the heat goes off soon, and at other times it lasts three weeks or even a month. Perhaps too this great heat of corn full of caterpillars may proceed from the moisture which those insects occasion, and from thence may arise a fermentation capable of hatching the eggs, of making the caterpillars grow, of hastening their transformations, and of bringing forth the butterflies, at the same time that it damages the corn, which thereby contracts a bad smell. It is certain, that when the harvest is wet, and warm rains fall at that time, the corn heats very soon, and then these insects make an extremely rapid progress. The heat which the corn contracts is doubtless very favourable to that progress, and the insects certainly may then attack the grains softened by the moisture, more easily than they can those which are hardened by drought. Accordingly, in 1760, a year in which the heat was great, and the air very dry, the corn in Anjou kept cool so long that many of the inhabitants of that province thought there would be but few insects, and that the great heat of the sun had killed most of the caterpillars. They flatter themselves with the same hopes whenever these insects do not appear in great numbers quite so soon as usual, and imagine that few or none of them will come afterwards: but in that very year, which they thought so fatal to insects, we saw butterflies come out of the ears of corn while they were in the reapers hands; we saw still more fly about the sheaves laid up in barns, and an inexpressible multitude upon the surface of corn deposited in granaries, though neither of these grew very perceptibly till about the middle of September. In 1761, the corn was so much heated on the 8th of September, that though the outward air was of the same temperature as that in the vaults of the observatory at Paris, Reaumur's thermometer placed in one of those heaps rose to 53 degrees, (131 of Fahrenheit's). The great heats of the summer had therefore only deferred the evil, and perhaps lessened it a little. But this dreadful scourge returns every year. These caterpillars, inclosed in their grain of corn, and sheltered in barns or granaries, are screened from the vicissitudes and rigour of the air which destroy other insects that are exposed to them.

"Let us now review our insect in all the seasons of the year, in order to try to find under what circumstances it may be attacked with most advantage.

"At harvest-time, we saw butterflies come out of some grains, which were already empty and entirely consumed, before they were reaped. Doubtless these first butterflies couple and lay their eggs upon the other unreaped ears, and probably part of those eggs are destroyed by the action of the flail, when the corn is threshed and cleansed soon after its being cut: but as the caterpillars are hatched very speedily in hot weather, and many of them can, as in fact we saw them, enter into the corn that is reaping, and shelter themselves there, they will do all their mischief, if speedy care be not taken to stifle them, as we shall hereafter observe.

"The reaped corn is laid up in sheaves in barns, till the husbandman can find time to thresh it, which is sometimes sooner, and sometimes later. The corn thus piled up, heats; and the transformations of the insects inclosed in it are then

the sooner effected. When any of these piles of sheaves were stirred in our presence, we saw butterflies come out of them, and the grains from which they issued were empty of flour, and absolutely spoiled. The moment these butterflies are out of their prison, they couple, and lay their eggs upon the ears which they find in the barn. Part of these eggs, and of the young caterpillars, might certainly be destroyed by the flail and winnow, as we said before, if they were used speedily.

"Many peasants in the country we are speaking of, make all the haste they can to thresh their little crops, which they generally do upon a very dirty floor made in a hurry in the open air. They winnow and cleanse their corn as soon as it has been threshed; and the empty grains are then partly separated from those that are full, by the wind, which carries the lightest away with the chaff.

"As the dirtiness of the floor on which the sheaves are threshed, fouls the grains of corn, these people wash them, and thereby take off such of the remaining light grains as swim upon the water. They likewise separate the grains of which the caterpillars have eaten so much of the mealy substance as to render them specifically lighter than the water: but the grains of which the caterpillars have not eaten much of the flour, sink to the bottom with sound ones: and the caterpillars devour those infected grain after they are softened by the water, much sooner than those which are thoroughly dry.

"Most of these peasants knowing the ill fate that will attend their corn, sell it as soon as possible to dealers, who carry it into the neighbouring provinces, and with it the contagion. This is the real cause which spreads the evil. Others have their corn ground immediately after harvest; and this is the best method they can take, though not without its inconveniences: for, in the first place, there are not mills enough in the country to grind immediately the whole produce of the crop; secondly, the meal of corn gathered in a wet harvest will not keep long; and lastly, though the friction of the mill-stones undoubtedly destroy almost all the insects, it is not certain but that some of them may escape, and in that case they will thrive, and go through their several metamorphoses, first into *aureliæ* and afterwards into butterflies, in the flour, as we have experienced in the manner before related.

"Several of the inhabitants of the country in question lay their corn up in granaries, in order therewith to pay their rent, which in general, is not due till the beginning of October. From these heaps of reserved corn, issue multitudes of butterflies, which, as we have observed, couple and lay upon that corn an immense quantity of eggs, from whence proceed caterpillars which get into the grains, and devour their inside during the whole winter.

"It is highly probable that, in mild and moist autumns, some of the first hatched caterpillars may be changed into butterflies early enough to produce a second generation before winter; nor will this seem surprising to those who know how rapidly warm weather makes these insects go through all their metamorphoses. But, independent of this it is certain that butterflies are continually seen to come out of all the heaps of wheat, barley, and rye, in Anjou, during the whole summer, and till the autumn begins to grow cold; that numbers of live caterpillars are found in the grains during the winter; that many *aureliæ* are found in them towards the end of May; and that prodigious multitudes of butterflies issue from them as soon as the weather begins to be hot, that is to say, towards the middle of June.

"Thus we see that there are, in a manner, two flights of butterflies; one which appears from harvest time till the weather grows cold in September, and the other which appears in June, and lasts till harvest. The former, in our opinion, proceed partly from granaries in which corn of the preceding year has been laid up with young caterpillars in it, and partly from the eggs first laid upon the ears, towards the end of May, or upon the new reaped corn; so that the second flight begins just as the first flight ends.

"A circumstance well worth observing, and which will be more particularly noticed hereafter, is that most of the butterflies of the summer flight remain in the granaries, fast clung to the threshed corn, upon which we have seen them couple and lay their eggs. It looks as if these butterflies knew that there then no longer is in the fields any corn fit to feed their posterity. On the contrary, those of the spring flight endeavour to get out of the granaries, and do in fact get out in vast numbers, through the windows, to

spread in the fields, and lay their eggs upon the yet green corn."

That this is really the case, and that these insects are of the species called *phalænæ*, appeared evidently from several very accurate observations, made by Messrs. Duhamel and Tillet, and of which it may be sufficient to mention here only the following.

In June 1761, they went, at different hours of the day, into granaries where there were heaps of corn infected with these insects. While the day lasted, they perceived a multitude of butterflies which stirred a little upon those heaps, but did not quit them. When they returned into the same granaries a little after the sun-set, they saw those butterflies rise from the corn, and fly to the walls, where they settled for a while; after which they took their flight in vast numbers, through the windows, and went off with such rapidity that they soon got out of sight. If Messrs. Duhamel and Tillet went back into these granaries at ten or eleven o'clock at night, they no longer saw so great a number of butterflies, and those that did remain seemed to be less agitated.

To be still more perfectly acquainted with some circumstances of the life of this insect, they put different sorts of corn into small closets, in September 1760, after having pasted white paper all over the walls and ceiling. In the beginning of June 1761, these closets swarmed with butterflies, which seemed to be pretty quiet during the day, and were seen to be greatly agitated towards the setting of the sun: but they could not get out of the closets, because the windows were closely shut. On the 9th of June, towards eight o'clock in the evening, one of the closet-doors being opened, a prodigious number of butterflies immediately issued out, and, with surprising swiftness, traversed an opposite granary, without making the least stop, though several heaps of wheat lay in it. They bent their course directly to an open window of the granary, at some distance from the closets, and instantly hastened out. Several people, who were present, followed them with their eyes, till the ridge of a barn near forty feet off, and the decline of the day, prevented their seeing them any further. Our observers returned to the same closet at about ten o'clock at night, and then found the remaining butterflies very quiet, scarce one of them attempting to fly out.

These observations prove sufficiently that this species of butterflies is nocturnal, and that those of the June flight have a different instinct from those which do not appear till after harvest. These last remain upon the corn in the granary, and there couple and lay their eggs, from whence proceed caterpillars which penetrate into the grains as soon as they are hatched. The June caterpillars, on the contrary, act as if they knew that the blossoming of the corn is past, and that its ears are fitted to supply their posterity with necessary food. They seldom leave the granary before sun-set, unless dark clouds chance to beguile them earlier, in which case numbers of them become the prey of swallows and martins, which fly about the windows.

As these little insects fly very swiftly, and rise to such a height that the eye cannot follow them long, especially when the dusk of the evening begins to come on, Messrs. Du Hamel and Tillet were obliged to try several methods before they could be certain what became of them. The caterpillars which they found in the grains of standing corn made them conclude that the butterflies, when out of the granary, flew directly into the green corn, and laid their eggs upon its yet tender ears: but none of the country people, of whom they inquired, had ever observed them in the fields, or could give any satisfactory account of them. Another well attested circumstance, which strengthened their conjecture, was their being assured by persons of undoubted credit, that the corn which grows nearest to villages, farm-houses, barns, or buildings used for granaries, is always much more damaged by insects than that which grows at a distance from any habitation. Their own observations confirmed this fact; and their experiments, dictated by reason, soon proved that they had conjectured right.

Desirous to know what was become of the swarms of butterflies which they had seen go out of the granaries in June 1761, they searched all the neighbouring fields of every kind of corn, and beat even the surrounding hedges, at all hours of the day, to no sort of purpose: not a butterfly could they find, excepting a few dead and dried ones entangled in spider webs along the outside of the corn. This

very circumstance led them to the discovery they were in quest of: for, rightly reflecting that these insects, which neither they or any other persons had been able to find in the fields in the day time, must certainly be of the phalænæ or nocturnal kind; they, without farther delay, set out with a candle and lanthorn, repaired to one of the corn-fields which they had visited in the afternoon, and, in the night between the 5th and 6th of June, soon descried a great number of the very butterflies they were seeking for, upon the beards of the ears of wheat. They returned to the same spot early the next morning, and could not then find a single one.

From that time they saw and shewed to whoever chose to see them, a great number of these butterflies upon the standing wheat and barley. Some were upon the beards, and others had made their way to the point of the grain. Scarce an evening passed without their seeing some coupled. Though every circumstance concurred to prove, and indeed left no room to doubt, that these butterflies were the same as those which infested the corn in granaries; yet, to be thoroughly convinced, and to convince others, in this respect, they took some of them from off the ears of corn in the field, examined them with a microscope, and found them to be of the very same species. A farther demonstration of this resulted from the following incidents. M. de Taponnat, one of their friends in Angoumois, had, in a small granary, several heaps of wheat differently prepared, which he kept by way of experiment. Messrs. Duhamel and Tillet observing numbers of caterpillars in two of those heaps, advised him to put that corn into an oven properly heated, in order to prevent the dispersion of the butterflies, which they knew would otherwise infallibly proceed from thence: but this was neglected. On the 21st of June, about seven o'clock in the evening, they visited this little granary, and found upon the corn a multitude of butterflies in great agitation, and of which a considerable number soon flew out of the windows. They took leave of M. de Taponnat, assuring him that this flight of insects would soon light upon his standing corn. When they were gone, M. de Taponnat had the curiosity to step out, to see whether any great quantity of butterflies still continued to issue from his granary; which he could easily do, as the window was very low. He was amazed at the numbers he saw fly out at that one window; being, as nearly as he could compute, about fifty in a minute. He observed, that they directed their flight towards a field of wheat not far off, and thereupon went thither with five or six other persons, all of whom saw them arrive in swarms, proceeding chiefly from the granary. They saw many of them light upon the ears, and on their running a cane gently over the awns, beheld them rise by dozens at a time. M. de Taponnat was so struck with this sight, that he ordered the window of his granary to be shut the next day, and his corn to be put into an oven properly heated as soon as possible.

A clergyman in the neighbourhood, who had a little barley infested with these insects, could not be persuaded to do the same, though his whole quantity was but a few bushels. The consequence was, that a multitude of butterflies were soon seen to proceed from the window of his granary, and spread so thick over an adjacent field of barley, that not an ear could be found without several of them upon it.

These facts confirm all the former remarks of our accurate inquirers, who, after observing that the fittest time to find these butterflies upon the ears of standing corn, is about half an hour after sun-set, continue thus:

"On the 10th of June about eight o'clock in the evening, we visited the fields around la Rochefoucault, and then perceived only a few butterflies upon the ears of the corn: they were greatly agitated; and we soon after saw numbers of the same species arrive on all sides, but chiefly from certain mills on the banks of the river.

"Those that were upon the corn flew away as soon as we approached them with a light. This was probably the time of their arrival. Towards nine o'clock we renewed our search, and saw many of them cling to the ears, either actually coupled, or seeking to couple. The light did not affright them then, and we had time enough to examine them with a microscope. We found fewer of them towards midnight, and could not see any early the next morning. It is not to be supposed that the dispersion of these butterflies happens always regularly at the hours before-mentioned; for we have observed several variations, which depend on the warmth of the air; and they commonly settle upon

the corn earlier when the sun is overcast with clouds just before its setting.

"As we have not ever met with these butterflies in the day time, it may be asked, where they then retire to? This question deserves an answer. We have searched for them in vain in hedges and among the blades of corn. Light certainly incommodes them; for when we exposed to the sun vessels in which some of them were inclosed, they hid themselves in the shade formed by creases of the paper at the bottom of those vessels, in such manner that we were sometimes puzzled to find them again. One day that the sun shone very bright, we took two crystal cups, into one of which we put a few grains of wheat with some butterflies, then covered it with paper, and placed it upon its bottom in a garden exposed to the sun. We put some butterflies into the other, but not any corn; and placed it close to the former, with its bottom uppermost, that the butterflies might receive the full heat of the sun: and lastly, we set one of M. de Reaumur's thermometers upon the ground, just by these cups. When the liquor had risen to from 45 to 50 degrees, (from 112 to 124 of Fahrenheit's), we saw that all the butterflies in the cup where there was not any corn, were dead: in the other, only some were dead; because most of them had found a shady shelter, either by making their way into the grains, or by hiding themselves under the paper cover. We knew before, that these butterflies are greatly agitated, and flutter very much when they are exposed to the sun; but we could not tell whether that proceeded from pleasure or pain. The doubt is now removed; and we are of opinion that they retire to a cool or shady place during the day time, and that their smallness prevents our finding where they are hidden, which may perhaps be in woods or thickets, in crevices in the barks of trees, or in the earth."

That the caterpillars which produce first aureliæ, and then these butterflies, can, and frequently do, live under-ground, that they can pass the winter there inclosed in the grain with which they are sown, and even undergo their several metamorphoses in the earth, so as to arise from thence, in the form of butterflies in the spring, has been demonstrated by the following experiments:

In May, 1761, Messieurs Duhamel and Tillet planted, in a garden pot, corn in which they knew there were caterpillars. They buried it an inch deep, watered it carefully, and saw that, notwithstanding plentiful rains had fallen upon it, those caterpillars changed into aureliæ just as if they had been in a granary. These aureliæ produced butterflies, which, weak as they were when first hatched, soon made their way out of the ground.

To be the more certain of their power, with respect to this last article, the same gentleman put some thoroughly dry, and well pulverized earth into a glass vessel, then layed upon that earth a layer of corn in which they knew there were aureliæ, and covered this with equally well dried and pulverized earth, at least half an inch deep; after which they tied a paper over the vessel, to keep in the butterflies, in case they should pierce through the upper mould. In effect, they did pierce through it, coupled, and laid such quantities of eggs as covered its whole surface.

To see whether these insects would rise as easily from underneath a stiffer earth, and what effect their being buried deeper would have, a wooden box was divided into three partitions, and filled with common mould taken out of a kitchen garden. Corn known to be infested with these caterpillars was planted an inch deep in one of these partitions, two inches deep in another, and three inches in the third. All of them were then covered with a glass frame, and butterflies soon appeared in each of the divisions; but they were far the most numerous in that where they had been buried but an inch deep. In another trial, a number of infested grains were covered with a still stiffer earth, wetted, and pressed down; and not any butterflies appeared there. At their first coming out of the ground, they are rumpled, as when taken out of a chrysalis: but after resting a moment, they shake their wings, set them right, and soon take their flight.

That some of these butterflies can, and do come out of the ploughed ground which has been sowed with infested seeds, is certain: but Messieurs Duhamel and Tillet are thoroughly satisfied that their number is but small, that most of the caterpillars sown with the grain perish before they can reach the surface of the earth, and that the butterflies which proceed from granaries are the great source of the increase of this insect: for, say they, the grain which contains

tains a young caterpillar will grow, if its germ has not been damaged; and as its mealy substance is consumed by the plant, the caterpillar must die for want of food. Besides, as it proved by the last mentioned experiment, the butterflies cannot pierce through a close and hardened earth; which generally is the case of ploughed land that has been exposed to the winter rains.

After observing that the two sexes sometimes unite a second time after separation; that the female deposits her eggs almost immediately after they are fecundated, in small parcels of from 6 to 30, and that each female lays in all from 60 to 90; adding to this, that there are generally three flights in a year, one at the latter end of May or in the beginning of June, a second in August, and a third in some of the subsequent months, during which a fourth also, and even a fifth have been known; we may, from the following calculation, form an idea of the astonishing multiplication of these insects, and consequently of the ravages which they must make where they have established themselves.

Every female produces from 60 to 90 eggs, of which 75 is the medium: but let us suppose the number to be no more than 70. Let us suppose also, that of those 70 eggs, one half only produces females, which makes the number 35. This multiplied by 70, the number of eggs laid by each, gives for the second brood, from a single insect, 2450: the half of this number, supposed to be females, is 1225, which multiplied by 70, gives 15,750 for the third brood. The half of this number, being 42,875, multiplied by 70, gives for the fourth brood, 3,001,250; and the half of this, 1,500,625, multiplied by 70, gives 105,043,750 for the fifth brood: so that supposing five broods in a year, each female butterfly of this species that exists in May, produces, before the May following, no less than one hundred and five millions, forty-three thousand, seven hundred and fifty individuals of the same kind.

It is not agreed whether these insects prefer wheat, barley or rye. The observations and trials made by Mess. Duhamel and Tillet seem to prove, that they attack indifferently which ever lies most convenient for them; and that they do not spare maize, when it is stripped of its stalk and laid up in a granary, where they can come at the soft inside part of the grain; or even oats, though it be the common, but mistaken opinion of the people of Angoumois, that this last grain is a preservative of others, especially of barley, when sown with it, or intermixed in the same heap.

M. Tillet inclosed several ears of standing oats in a wide mouthed glass bottle, and put into it some of these butterflies; after which he covered the mouth with a piece of fine

linen. The butterflies coupled there, laid their eggs upon the ears, and several caterpillars which proceeded from those eggs, actually introduced themselves into the grains. A manifest proof that, though the pendent positions of the grains of oats, whilst growing, may be inconvenient to the female butterflies, many of whose eggs may be washed or blown off, more easily than from other corn, before they are fixed by the viscous matter which fastens them to the husks; yet the corn caterpillar can live upon oats. What is still more extraordinary is, that grains of wheat, barley, rye, and oats, were mixed together in a glass vessel, into which some of these butterflies were put: and the oats were damaged by caterpillars, as much as any of the other grain: though it is certain that these insects do but little mischief to oats in the granary; happily for the poor people who make bread of this corn.

In guarding against these insects, the farmer has three objects: 1, to preserve his grain for seed; 2, to keep it, for food and market; and, 3, the total destruction of the insects.

To preserve the corn for seed, it should be threshed out as soon as possible, in order to prevent the transformation of the caterpillars brought from the field, which otherwise soon become butterflies; whose prodigious number of eggs would exceedingly increase the evil. For want of this precaution, two thirds of the store of seed-corn has frequently been destroyed.

The seed should either be dried in an oven, in which the heat should be strong enough to kill the caterpillars, without destroying the vegetative power of the grain; which will be properly effected by 124 degrees of heat on Fahrenheit's thermometer, or soaked in a strong lye of wood-ashes and quick-lime, heated to such a degree that the finger can just bear it. Let the corn contained in a basket be stirred in this lye, and the grains skimmed off that float on the surface. When the corn has been thus soaked for about two minutes, the basket which contains it should then be lifted up, and suspended by two poles, till the lye is drained off. The grain should then be spread very thin on the floor of a granary to dry, while a second basket-full is prepared in the same manner. The corn thus steeped, and well dried, will keep a year and continue fit for sowing.

By following the above directions, corn may be preserved from the ravages of these or any other similar insects that prey upon it. *Histoire d'un Insecte qui devore les Grains de l'Angoumois.*

RUTTER-JAGS, flowers of the wild trefoil.

C.

CABBAGE, the name of a plant well known, and of which there are several species cultivated.

Cabbages have lately been cultivated for the food of cattle, and by several experiments found to produce a very large increase when managed according to the principles of the New Husbandry. M. de Chateaubieux has been very particular in relating the success of his experiments, which we shall therefore give the reader.

"I began, says this curious gentleman in a letter to M. Duhamel, by retrenching the dung; though the spot I chose for my first trial had not received any for several years. It had indeed been well prepared by ploughing the preceding year, when one half of it bore barley, and the other oats. I now made it into a bed, the middle of which was directly over the last year's furrow. I ploughed this bed on the twenty-fifth of September, 1751, in the same manner as if

it had been intended for wheat. I planted on it a single row of white cabbages, which I watered to make them take root the better. The length of this bed was one hundred and sixty feet, and its breadth six feet seven inches.

"That I might be able to make a just comparison between the cabbages of this bed, and those of the kitchen, I planted a spot of ground in the latter, the same day, with the same sort of plants. This spot had been extremely well dug, and plentifully dunged by the gardener, who took all possible care of these plants during the summer, and weeded them as often as was necessary.

"Instead of cabbaging, most of them ran up in height: upon which I plucked them up, and planted others in their stead.

"I bestowed the same care and culture on my row of cabbages in the bed, as if they had been wheat.

"On

"On the ninth of March, 1752, the alleys were stirred with the plough. On the twenty-fifth of April, I gave them a second stirring with the cultivator. On the third of June they had a third stirring with the plough: and on the twentieth of July, I made my gardener hand-hoe them. for fear the plough should damage several stalks of wheat which grew on the next bed, and were bent, but not lodged.

"These cabbages were never watered, except once, which was at the time of planting them; and yet they were always crisp and firm, even in the hottest days. By this easy and expeditious culture, they attained all the perfection that could be desired; and surpassed those of the kitchen-garden, as much in goodness, as they did in bulk. Most of them weighed between fifteen and eighteen pounds, and the smallest between eight and ten. The weight of all the plants which grew on this bed, was 840 pounds."

The circumstance of the cabbages continuing firm and crisp in the hottest weather, is remarkable. Mr. Baker, in the following experiment upon cabbages, makes the same observation. This is the effect of good and deep hoeing, and is taken notice of by Mr. Tull as the constant effect of horse-hoeing, and is so in some measure of hand-hoeing, when well performed and deep. The earth being made fine by good tillage, imbibes the dews, and when hoed deep, retains them: they penetrate deeper into the loose open soil in the night, than the sun and air can exhale them in the day: the roots of the plants are thus refreshed, and the earth is kept cool in hot weather, which greatly promotes their health and growth: for heat and moisture are principal agents in vegetation: this appears agreeable to reason, and is confirmed by experience. It is an observation of great importance in agriculture. It is so to farmers, who by good hoeing may keep their crops in health and vigour in dry hot weather, when the unhoed crops are parched and stunted by it. And it is no less so to gardeners; who by diligent and deep hoeing, might save themselves much of the expence and trouble of watering their plants. It is proper, however, to take notice, that this good effect of hoeing, is in consequence of the earth being fine, loose and open. Hoeing of close, dry, hard earth, does not open and pulverize it at once, nor until it has been well broken and exposed to the air, and vicissitudes of the weather. It is this that pulverises land beyond what is practicable to be done by hoes, ploughs, or any instruments of husbandry; and for this reason, those who would obtain the full benefit of hoeing, should be careful to keep their land constantly in good tilth; and when interrupted by the rains and snow in winter, they should be careful to take the first opportunity of dry weather to renew the tillage, which will undoubtedly prepare their land to receive the benefits of hoeing, which are very great, besides subduing the weeds.

The intelligent and careful cultivator Mr. John Wynn Baker, in a report he made to the Dublin Society, tells us, that he also cultivated cabbages after the manner of the New Husbandry, on a piece of ground that had bore potatoes the preceding year. It was manured with a compost of lime, earth, and dung, perfectly incorporated. On the sixth and seventh of July 1764, he planted one row of cabbage-plants on the middle of every ridge, of about an acre of ground, the plants in the rows being two feet from each other, and the rows five feet asunder. On the sixth of July a fine rain fell, and more on the eleventh and twelfth, which saved the expence of watering, and secured life to the plants.

On the seventh of August, the cabbages were horse-hoed, by taking off, at one furrow of the plough, only one side of each ridge, close to the plants: in this manner they remained till the twenty-fifth, when the plough was run along in the same furrow; by which, with the first furrow, the soil was ploughed about twenty-one inches deep. This being finished, the earth was immediately returned back to the plants, which afforded them fresh nourishment; and in order to give their roots time enough to penetrate this fresh earth, which by the horse-hoeing, was become very fine mould, they were suffered to continue in this state until the 12th of September; when they were again horse-hoed, by taking off the other side of every ridge; and on the twentieth the furrow was deepened in the same manner as the former, the mould immediately returned to the plants. On the eighteenth of October a small furrow was thrown up to each side of every ridge, which finished the culture, and restored the ridges to the form

in which they were when the plants were put upon them.

The plants all grew luxuriantly; and in the hottest weather were infinitely more brittle in their leaves, than any in the neighbouring gardens; which is a certain indication of health in these kind of plants.

The horse-hoeing was so effectually destructive to the weeds, that the expence of weeding was a mere trifle.

On the eighth of December, Mr. Baker cut one row of these cabbages, they then beginning to decay, which is indicated by their bursting. The number was two hundred and fifty-eight, and they weighed sixteen hundred weight, three quarters, and twenty-one pounds; which, at an average, is seven pounds and near six ounces for a cabbage.

The produce upon an acre, on weighing this row, which was five hundred and sixteen feet long, amounted to twenty-three tons, four hundred, two quarters, and fourteen pounds; which Mr. Baker observes is, at least, from ten to seventeen tons less than the product would have been upon an acre, could he have obtained the large, late, Dutch cabbage.

The ingenious Mr. Randall, in a treatise lately published, entitled *Semi-Virgilian Husbandry*, has given us the following method of cultivating cabbages according to his newly proposed system, which is nothing more than the New Husbandry, executed by the ordinary implements.

The soil on which the cabbages are to grow, is supposed to be a loam in good heart; and as the *Semi-Virgilian Husbandry* requires only that the soil should be made exceeding fine, without the assistance of any dung, therefore the land destined for these cabbages must be thrown up to be fallowed, that it may enjoy all the advantages of a winter and summer fallow, so as to be exquisitely well prepared for the reception of the plants about Old Michaelmas.

As cabbages extract their nourishment from a considerable depth, as well as from the surface of the soil, it will be necessary that the land should be double trenched during the time of fallowing.

The loam, immediately after harvest, is to be turned up, and the workman is to go as deep as he can with his plough, another plough is immediately to follow in the same furrow with a higher earth-board, which will cast the mould over, and bury the stubble, if it was not before, by some other method, destroyed: in this manner the field will, as it were, be turned upside down, double spitted more than a foot deep, and the stubble will be sooner rotted. The harrows must then make the ground as fine as the season will at that time permit.

The next thing to be done, when the weather will admit of it, is to double-trench the land, and lay it up till the spring in sharp ridges.

Here Mr. Randall makes a very sensible and useful observation, namely, that the teams must not be suffered to go upon the ground till it is first tried with a spade, to see whether the soil is dry enough to the depth it was ploughed before; for treading the ground in any season of the year, when it is not in order, or sufficiently dry, is a very destructive practice. The standard in this case recommended, very properly by Mr. Randall, is, when the mould crumbles or feels mellow between the finger and thumb, instead of adhering, so as to judge by the touch, whether the parts will give way to the tread, or whether the earth be in such a state of cohesion as to be padded under the horses feet.

The following directions are given for performing the ridge-work, or laying up the soil for the winter.

The ploughman is to begin in any part of the ground he pleases, and go one bout, throwing the furrows in such a manner, that they may form a little ridge. When this is done, the horses must turn to the left, and the share-point be put to the end of the trench; then go another bout in the manner already mentioned, the horses again turning to the left, and continuing to go on in this manner, till the piece of ground is ploughed throughout. If the plough begins close to a hedge, it may save some little trouble in going over more ground than is necessary; and where it can conveniently be done, the plough should cross the path the horses went in the first operation, as this cross-ploughing is often a means of stirring the baulks made by a former ploughing.

The first bout should be drawn out as straight as possible, as the rest will depend upon it; and if the hedge is not straight enough to allow this, the ploughman should begin at some distance from it for the advantage of a straight line, leaving the skirtings near the hedge to be last finished. The land will now lie in gentle rising ridges and regular valleys, ready for the third operation.

In this the ploughman is to go the very same ground over again, with the same plough, or one a little wider and higher in the earth-board, and throw the mould over the right and then over the left side of the first ridge, going four inches and a half, or five inches deep, and turning off, as before, continually to the left. This trench-work requires four horses to a plough; and the second team, in the first operation, if the ground be hard, and has not been stirred for a long time, may require five horses, but not more.

The ground will now lie in sharp ridges, and deep trenches; and if the work be well executed, the bottom of the hollows or little ridges, will be near twelve, or at the very least nine inches below the basis of the ridges, or surface of the ground, and about eighteen inches wide; and the distance from the top of one ridge to another will be near three times and a half the width of the plough, as it runs in the ground after the horses: the breadth of the ground, which each ridge stands upon, being about fourteen inches.

In this situation the land is to remain till the month of February, when the first opportunity that occurs in that month, the ridges and the whole ground being of a proper dryness, is to be seized for the next operation.

In the first place, a pair of ox-harrows, or the heaviest of all, in many counties called drags, are to be yoked together, and the cattle are to go a-breast, not in a line; but two on one side, and two on the other, and to walk in the trenches, having a ridge between them; by which means the harrows will move on the crown of one ridge, at the centre; and the outward parts, when well guided, will reach to the top of a ridge on each side that which divides the cattle. The harrows, which are to go only once in a place, will greatly reduce the soil, and pulling down the ridges, the soil will be in a manner level, yet not so even but that the ploughman may with ease discover where the ridges stood. The ploughman is now to proceed in the same manner as when he threw the ground into ridges, keeping the plough-sharp along the crown of a ridge, which will be visible enough after once harrowing. When he has gone one bout, which must be on the tops of two ridges, the furrows will be turned to the right, and lie pretty flat on that part which was a trench before: thus proceeding throughout the field, the whole will again lie in single ridges, and single trenches; but if the weather permits, as soon as this operation is performed, the soil must be double trenched, in the same manner as the second ploughing of the second operation, when it is laid in ridges for the winter; thus the whole field will again lie under the double work of high ridges and deep trenches.

We are now to suppose the ridge-work brought forward to the latter end of the spring, or the beginning of the summer, when weeds begin to grow plentifully.

The ridges must, at this time, be pulled down as before, with heavy harrows; but instead of going once, the servant must go twice in a place, and then use the lighter harrows, and afterwards the finest of all, in order to prepare the ground in such a manner, as to induce a large crop of weeds to grow: but if the weather will permit the horses to tread on the ground without spoiling it, the weeds must not be suffered to grow more than a plough can bury by going the usual depth; and when the weeds are turned down, another plough is to follow, and to cover the furrow of the first, after which the land is to be harrowed down again as level as possible, in order to prepare it for yielding another crop of weeds.

When the second crop of weeds is got to a tolerable height, it may be proper to try, with a spade, whether the first weeds, which were turned down to the bottom of the second statum, are sufficiently putrefied: if they are, the land is to be ploughed as before; but if they are not, the weeds now growing must be turned down by one ploughing by such a depth only as to bury them, and the land must be afterwards levelled with a loaded bush-harrow.

We may suppose, that by the middle of August, the weeds first turned down will be rotted; therefore at that

time the third crop of weeds may be turned down by the double spitting, already mentioned, and left in this condition till there is occasion to make use of the land.

Just before the time of planting the cabbages, the land must be laid as level as possible, and by frequent harrowings it will not be inferior to a garden for fineness.

The ground being now ready to receive the plants, it will be necessary to point out how they are to be raised and transplanted, which cannot be better done than in Mr. Randall's own words.

"The ground on which the cabbage-seed is to be sown, must be exceeding fine, in great heart, and absolutely clear of weeds, otherwise it will be difficult to raise the plants in perfection; and, in order to this, the richest and cleanest piece of ground must be fixed on, immediately after the same harvest, when the fallow for cabbages begins, and the nursery for the plants must have all the advantages of fallowing equally with that which is to receive the plants; and about the middle of July the cabbage-seed is to be sown: but as husbandmen are unacquainted with the manner of sowing this seed, it will be necessary to employ an honest gardener to perform this business as it ought; and the same person may be also employed to prick out the young plants upon another piece of ground, in great heart, and clear of weeds, lest they should draw one another before the season arrives when they are to be transplanted out for good and all, on the ground whereon they are to stand for a crop: one perch will raise plants sufficient for more than an acre of cabbages, from two ounces of seed, but it is better to have a great choice, as there will be some puny plants in the nursery, let the gardener, or those who prepared the ground, take what care they can; and the seed must be procured from Scotland, as the Scotch cabbage-seed is the properest for this vegetable, when designed for the use of cattle, as they will grow late, and to an enormous size, when they have all the advantages of ploughing among them, during the time of their growth.

"If the gardener is diligent, the expence of thus pricking out the tender plants, at six square inches, on about six perches and a half, will be about four or five shillings; but if the owner can depend upon the nursery's being clear of weeds, though the weather be very growing, there is a much cheaper method of raising the plants: for if the gardener, with the above two ounces of seed, to be sown on six perches and a half, takes care to set out the plants with a small hand-hoe, before they begin to draw one another, he may hoe up the puny, and leave none but the stoutest plants, at a proper distance, suppose six inches, asunder, rather under than over. While he is doing this, he may assist the plants he suffers to stand, by giving them a little mould to their stems, and checking any weeds that appear; by this means, the plants will grow to perfection, and need not be removed till they are transplanted out for the crop: and if the gardener sows the seed, and leaves the plants on the same ground, about six inches asunder, one perch will transplant twenty-five, and consequently, six perches and about a half, will transplant an acre, from two ounces of seed on six perches and a half, and set out at six inches from each young plant.

"When the plants are thus raised on the nursery, by either method, pricking them out, or setting them out with the small hand-hoe, and the season is arrived for transplanting them on the ground they are to stand on to be cabbages, the next business is to consider the distance they are to stand from each other, when transplanted; and here we must first observe, that gardeners usually set them about two feet and a half from each other throughout the piece of ground allotted for that purpose; and, during their stay on the soil, they only hand-hoe and earth them up, when on the bed they are transplanted upon, without ever giving themselves any farther trouble about them, being no ways anxious to make them grow to the largest size which they are capable of.

"In an acre there are 4840 square yards, which is about sixty-nine yards and a half every way; but in order to proportion an acre in a piece of ground, if the length be measured, and the above number of square yards in an acre, be divided by the length, the quotient is the breadth, and both divisions multiplied together will give 4840 yards. Now, as gardeners plant their cabbage-plants at two feet and a half asunder, this is allowing six square feet and a quarter for each plant, and makes the number of about 6970 plants on an acre; and plants set in two rows, at two feet asunder, and the plants set two feet

feet from each other in those rows; and then measuring out four feet and a quarter from one of those rows, and setting two rows more in the same manner, and so on throughout the ground; when the plants are set in this manner, the number of cabbages will be about 6970, which is the same as the gardeners raise on an acre, and the liberty of ploughing on one side of every row, or in the interval, and horse-hoeing between the narrowest rows, or the partitions.

"When the proper season arrives, about Old Michaelmas, or a little after, and the plants are to be set, as above, first one row the length of the ground, at two feet distance from each other; and, when this is done, then another row in the same manner, at two feet distance from the last; and, when this is done, another row must be planted, in like manner, at the distance of four feet three inches from the last; then another row of plants, at two feet distance from the last: here, then, one system will consist of one partition of two feet, and an interval of four feet and a quarter, and of two plants to each system: for four feet and a quarter, added to two feet and then multiplied by two feet, the distance of the plants in the rows, gives the parallelogram for two plants, or twelve feet and a half; and this, divided by two, gives six feet and a quarter; which is the gardeners distance, in their practice of cultivating these plants, or raising about 6970 cabbages on an acre, which is 2130 more than can be raised when they are planted in square yards throughout the acre.

"The ground being thus planted, we are now to conduct these vegetables through all the stages of their growth, and to help them to nutritive principles in the state of their greatest exigency; and, in order to this, at the beginning of winter the ground must be taken good care of; not only to keep it dry, but also to drain off the chilling wets from the bed of plants, which, as was said before, contains two feet. The first thing, then, to be done, at the approach of winter, but when the soil is dry, is to throw the intervals up into a sharp ridge, at two bouts, twice in a place, and as deep, each time, as the plough can go; this ridge-work, and double spitted, may be performed very well at two bouts, as it will allow nine inches in the middle of the interval, when the ploughman begins to turn the mould of the first bout on; and then, at the second bout, he will reach within three inches of the plants, if he measures the ground as he ought with his plough, in leaving nine inches, to turn the first furrow on, and keeps exactly nine inches in the second bout, from the land side of the first: however, he must so manage his two bouts, as to come no nearer than three inches on the beds of plants, whilst he is going the second bout.

"This operation being over, the ground will then lie in the following form: there will be a high two-bout land in the interval, taking up five furrows in breadth, or three feet nine inches, reckoning nine inches for the breadth of the plough, as it runs in the ground; and there will be a drain, on the outside of each bed of plants, nine inches wide, and, it being double spitted, or twice in a place, near a foot deep, at least cut so with the plough, though some mould will unavoidably fall back again, notwithstanding the care the ploughman may take to prevent it: and from the edge of the land side of each drain, or the breadth of each bed of plants, there will be two feet and a half of ground, which through the winter, will be kept very safe from too much wet by means of those drains; which is of great consequence to the plants, as much cold moisture brings on such a condensation and contraction among the component parts of this vegetable, that all the expansive principles in the spring and summer cannot unbrace; by which a dwarf state of the plant necessarily ensues.

"About the latter end of March, or the beginning of April, if the ground be dry, the ploughman is to go once in a place in the drain, or open trench, in order to deepen it still more, and to stir the mould; and the ploughman need not be in any pain for the fibres of the roots though he cuts or disturbs some of them in this operation: for as the fibres, which have stretched out into the bed, are undisturbed, he may cut off the outermost as near to the roots as he pleases, without doing any harm, unless he lets the plants down into the trench.

"When this operation is over, he must immediately throw down the ridge, by turning it back again, and leave an open trench in the middle of the interval, which may be done, very conveniently, at two bouts, without

overthrowing the mould upon the plants; but he must remember to go twice in a place with his plough, to keep the ground double spitted, which is of great consequence to the plants, and therefore he must not think of omitting it: after this operation, the soil will have a double trench, in the middle of the intervals, the width of twice the breadth of the plough, and about twelve inches deep, if some of the earth did not fall back again; and there will be mould, the quantity of what is thrown out by the plough, in double spitting, lying between the plants and this open trench, and which will be thrown pretty near the roots of the plants; which mould is to continue there till the wants of this vegetable require us to make an alteration, when we have paid some attention to the partitions, and also to the plants themselves.

"About the middle or latter end of April, if the ground is dry, the horse-hoe must be used in the partitions, and the ploughman must go as deep with it as he possibly can, in order not only to disturb the young weeds, but also to stir the earth, in the most effectual manner, within the reach of the fibres; but, immediately before this operation, the hand-hoe is to be used in the rows, between plant and plant, to check the weeds and refresh the mould about the roots, and the hoer must strike his instrument as deep as he can; and when the weeds, any time after this, appear above ground, in the partitions, or among the plants, the horse-hoe and hand-hoe must be used as before, but generally so timed, to be about a fortnight or three weeks after any alteration has been made in the intervals, that the fibres may have time, in either case, to heal again instead of being disturbed all at once.

"About the beginning of May, the ploughman is to draw the heavy harrow, and then the finer, over the intervals, in order to pull the mould into the open trench, level, and make the whole interval fine, and to prepare it for a ploughing. These harrows, being the same formerly mentioned, will do this business very well, without doing any harm to the plants; and if there be a good weight laid on them, they will do great execution, in pulling down the earth into the trench, and making the ground exceeding fine; which last article is of importance, as the plough will, in future operations, turn down this fine surface to a depth where the lower horizontal fibres will meet with it, and find plenty of nourishment therein.

"When the harrows have done their utmost, the ploughman is to go one bout, and throw up a ridge in the middle of the interval, if the ground is dry, and to double trench, as before; and in order to come near the plants, he may leave the breadth of about two furrows, on which to turn his bout, and then he will reach within six or seven inches of the plants with his share: when this is performed throughout the ground, the harrows must immediately be used as before, and then the ploughman is to turn all the mould towards the plants in two bouts, and double trenching, by which there will again be an open deep trench in the middle of the intervals: and about a month after this he is to use the harrows again, if the plants do not spread too far into the intervals; if they do, he must level the ground with his plough, or the horse-hoe, and then go one bout, and turn the mould on the breadth of a furrow and a half, still going twice in a place; and then the ridge, and open furrow, on each side, will contain about two and thirty inches, or the breadth of three furrows and a half, and he will have gone within nine inches of the stems of the plants, which is near three inches farther off them than before.

"In this form the ground is to lie a month, unless the season be very growing, and the weeds make a bold appearance; in that case, it may be necessary to disturb them sooner, by turning the ridge back again into the open trenches, and leaving the interval open in the middle, as formerly; and about Lammas, or a little before, the ploughman is to throw down the mould, into the middle open trench, and make the intervals level and fine, and this is the last operation arising from ploughing; the ground being now to remain, without disturbance, any farther than what ensues from the use of the horse-hoe, in the intervals, after the ground is made level, as before summer is over, there may come up some weeds, which must not be suffered to appear with impunity. It is presumed, that due care has been taken throughout the season of the partitions, and be-

between plant and plant in the rows, and likewise on the outsides near the plants, in the intervals, where the share and coulter could not reach without doing damage; and therefore, when the vegetables shut out the horse-hoe, in the partitions, or where the plough could not, or durst not, reach, the hand-hoe was to have done its office, to supply those wants, in the best manner it could.

"There is another method, which we have not mentioned, to transplant this vegetable on the ground it is to grow into a cabbage, which is cheaper; and it is this: those ploughmen, who can draw out a very straight furrow, set off first, and the persons, who are ready with the plants, put them into the trench, so made with the plough, at their proper distance from each other; and when the ploughman has gone the first bout, within the compass of three feet and a half from the share-point, he is to go another bout, to turn the mould into the first open furrow, so as not to bury the plants in this operation: and he will have gone these two bouts, one to open the ground for the reception of the plants; and the other to give them mould, by the time the people have supplied the furrows with plants, so that they may be all ready to start together again when the team returns to the head-land, from making his second bout.

The plants, on this occasion, must be placed upright in the trench, standing against the right-side of it, which may be done if the plough cuts the ground true, and the mould be well scooped out; and this will shew care in the person that holds it, and that his instrument is a good one. There must be a person to carry a gage, divided into two feet, in each division, ten feet in length, which will contain six points, the two ends, and four intermediate ones numbered from one to six; which division and points signify, that a plant must be placed in the open trench, directly against one of those figures, as the gage lies upon the ground, when the man who has the care of it, lays it down in a straight line, according to his office. In order to shew how the plants are to be ranged, in a most regular manner, exactly at two feet from each other, in the rows, we will suppose the ploughman to be just setting off to go his first bout: in this case the gager is to stand with his instrument, which may be a square piece of wood of about three inches over, or twelve in the girth, and numbered 1, 2, 3, 4, 5, 6, facing the right-side of the plough when it sets off; he must lay his right-hand just beyond figure 4, and his left just beyond figure 3, and, holding it in this manner, he will poise the gage very well, and lay it down, take it up, and remove it, without trouble to himself.

"Now, by standing about five feet, on the right side, from the place where the plough enters, and two persons with plants in their aprons, and a woman with a basket full behind him, standing on the left side, in this posture of the people, the plough is then to move on, and when the ploughman has passed by the end of the gage, the gager is then to lay it down, but in such a manner, that the end, number 1, may touch the place where the plough entered the ground, and the end, number 6, may lay in the right edge of the trench, on the mould turned out. The first man must fix his eye on figure 1, and, at the same time, the second man on figure 4, and each of them is to place a plant against his own figure; and then the first gardener puts down another at figure 2, and another at figure 3, and while he is doing this, the second gardener supplies figures 5 and 6, in the very same manner; and when they are supplying figures 3 and 6, the gager is to stoop down to be instantly ready to take up the gage, in the manner before directed, and the gardeners must take care to keep time with each other, that there be no delay in moving after the plough, in its progressive motion.

"The gager is instantly to remove his instrument, placing the left end close to the last plant, and the other end as before; and the gardeners are to take care of the three figures belonging to their office, the first man managing the three first numbers, and the second the three last. They may go on very fast in this manner, if they please, and, if they are three honest active men, no plough can out-travel them in making one bout: and in this operation it is expected of the ploughman, that he will make his horses step on briskly, which they may very well do with such light work; for, by the swifter motion of the plough, there is not only less expence attending this culture, but the trench is better cleared of the mould, and left square;

and the furrow is thrown so far to the right as to be in less danger of falling back again, which it may otherwise do from a creeping sluggish motion of the plough.

"Though two active gardeners, or husbandmen, when the latter are used to the nature of plants, and placing them in the ground, may get forwards as fast as the plough; yet in order to have the plants properly put against the figures, it may be better to have them take their time, and to proportion their work in such a manner, that they may finish by the time the team is at their heels, in ending the second bout. The gager and the two gardeners, need not be afraid of too much stooping; for the gager, when he stoops to put down his gage, has walked five feet, from the last place where he took it up, and, in fact, is only diversion and exercise for him; and the first gardener, when he stoops to put down his three plants, stepping along at the same time, in that posture, has six feet of ground to walk upright upon, which he may dispatch very nimbly, if occasion requires it; and the second gardener, in like manner; and as a person attends them at their backs with a basket of plants, they may without loss of time, be supplied, while they are walking, and take less or more into their aprons, or hands, as they see convenient, and consistent with dispatch.

"When the gager gets up to the far end of the ground, he must remember to keep on the furrow side of the plough, that is, on that side towards which the mould is turned; and the ploughman is now to receive farther directions how to proceed, when he has gone the two bouts, mentioned before. He was desired to draw out a very straight furrow when he first went up the ground, by taking sight of a tree, bush, or any other mark, exactly in the middle of the ground, and directly opposite to the place where he is to set off from, and which he judges to be in the middle; or he may use any method agreeable to himself, provided a straight line be only drawn out by the plough, for on this depends the regularity of all the rest of his bouts, and the operations of horse-hoeing and ploughing during the growth of the cabbages. The first furrow being thus drawn out, the next business is, to turn the horses to the right, and then to measure three feet and a half, from the edge of the land-side of the first furrow, or that edge cut with the coulter; and, making a mark at the end of three feet and a half, he must put the share point in there and come straight back again, keeping exactly three feet and a half from the far edge of the other furrow; and then, as was said before, he must go a second bout, to turn the mould into the open furrow where the plants are placed, which he may very well do without doing them any harm: if he proportions the depth of the furrows, where the plants are put, to their size, as they will be greater or less, just as the season has been for their growth on the beds whereon they grew.

"When all this is performed, and the ploughman is ready to set off again, in order to make another bout, he is to turn to the right, to draw out another furrow, which is to receive the plants which must stand four feet and a quarter from the row of plants now on his right-hand; to do which he is to consider, that the near edge of the open furrow next to him is the breadth of two furrows, or eighteen inches from that row of plants; and taking eighteen inches from four feet and a quarter, the remainder is thirty-three inches; and because the plants must stand on the furrow side, therefore we must add the breadth of the plough, which is nine inches, to the above thirty-three, which then will make three feet and a half from the edge of the open furrow next to him; and now measuring three feet and a half from that furrow, he must make a mark, and go his bout turning, to the right, and making the same mark from the outer-most furrow as before, and so proceeding straight back again.

"He is now to go another bout, to earth his plants, and when he has done this, he must still turn to the right and make a halt on the head-land, to consider what is next to be done: he knows the edge of the open furrow now on his right-hand, and next to him is eighteen inches from the nearest row of plants, and that the furrow he is going to open is for the plants to stand just two feet from the last row; and therefore taking eighteen from twenty-four, the remainder is six: and because the breadth of the plough is nine, therefore he must measure fifteen inches from the edge of that open furrow next to him, and making a mark there, that is the place where he is to set off: and when he gets to the far end of the ground, he must turn to the right,

right, and measure off fifteen inches from the edge of that open furrow next to him, as he comes down again: he is to go another bout to earth his plants, and then all things will be easy to him, as it will be only repeating what he did before; for as he is now going another bout, he is to measure three feet and a half, from the near edge of the open furrow next to him on the right-hand, and go straight up, and turning still to the right-hand, he must measure the same distance, as he comes down again from that open furrow, and when he has made another bout to earth those plants, he measures fifteen inches from the edge of that furrow; and when the plants are put into that he is now making and earthed, he then proceeds to measure off three feet and a half, which form the interval, and so on earthing, and then measuring fifteen inches alternately with the other, for the partitions, till all is finished.

“By which operations the whole ground will be planted with two rows, at two feet the partitions, and four feet and a quarter the intervals. Thus, then, upon the whole of these directions, when he first sets off, and gets to the far end, and turning to the right, he measures three feet and a half; when he has earthed plants, he measures three and a half for the next bout to receive the plants; and, earthing these, he measures fifteen inches for another row of plants; and, earthing these, he measures three feet and a half; and earthing these, he measures fifteen inches; and so on, alternately, three feet and a half, and earthing; then fifteen inches, and earthing; then three feet and a half again.”

The farmer will, doubtless, be glad to know what crop he is to expect from his land after all his labour: he has already been informed, that the number of cabbages on an acre, if they have all stood to maturity, will be six thousand, nine hundred and seventy: these may be allowed to weigh, one with another upon a medium, three quarters of a stone each; and if an ox be allowed to eat nine stone a day, that is, twelve cabbages, then six oxen will live three months on one acre of them; so that supposing one acre of turnips, raised in the common method of husbandry, to be sufficient during the same space of time for two oxen, we may still expect, in proportion, three times more benefit from the cabbages than from the turnips.

Mr. Randall assures us, that the oxen will grow very fat upon such food; that he has given it to many cows for a long time together, without perceiving the least disagreeable taste, either in the milk or butter: on the contrary, the milk was rather richer and sweeter: and that both oxen and cows are exceedingly fond of this food. The same may be said of sheep, which improve in their flesh very fast, and grow surprizingly fat on cabbages: yet has the mutton no disagreeable taste; so that there is perhaps no vegetable which will raise lean sheep of the largest breed sooner than cabbages. *Randall's Semi-Virgilian Husbandry, p. 315.*

It has been fully proved by experience, that cabbages are not only very agreeable food for black cattle and sheep, but also that they are very nourishing to them. They are completely fattened upon cabbages, and their flesh is as well tasted, as when fed upon rich pastures. Cows fed upon cabbages give a great deal of milk, and the butter made from it is excellent.

It was indeed for some time otherwise in the north of England, where cabbages were first cultivated at large in the fields, for feeding cattle, particularly the large Scotch cabbage; but it was discovered, that the bad taste of butter, when the cows fed upon cabbages, was wholly owing to giving them the decayed leaves: for when these decayed leaves are all taken off, and only the sound cabbages given to the cows, the milk and butter is perfectly sweet, and of a rich taste. In taking off these decayed leaves, there is no loss to the owner: for the dry cattle eat them greedily, and are much nourished by them.

It is a great recommendation of the large Scotch cabbages, that they produce very large crops, from thirty to sixty tons upon an acre, when cultivated upon good land, well manured, and horse-hoed; which is most conveniently done when they are transplanted upon ridges, between four and five feet broad, a single row upon each ridge, and the plants set about two feet asunder in the rows. The rows being thus far asunder, there is good room to horse-hoe them, which should be done deep, and repeated till the hoe-plough is shut out by the spreading of the plants: the ground between the plants is likewise to be well and frequently hand-hoed, and no weed suffered to grow large.

The expence of this culture is fully recompenced by the greatness, and nourishing quality of the crop; by the hardiness of these cabbages, resisting frost; and by their coming into use in winter and early in the spring: add to these advantages the improvement of the land, which is remarkable, the succeeding crops of whatever kind being extraordinary great. For an account of the feeding quality of cabbages, see LUCERNE.

In Mr. Baker's reports to the Dublin Society for the years 1769, 1770, and 1771, he has related a number of experiments that he made in these years, upon various sorts of cabbages. These he distinguishes into summer and winter cabbages. The summer cabbages were those raised from seed sown in March, were called spring or summer plants: and those from seed sown in August, were called autumn or winter plants.

In cultivating cabbages, the objects principally in view are, the quantity of food they produce, and their duration.

The quantity of food for cattle that they produce is very great; from twenty or thirty to fifty ton and upwards per acre. Black cattle and sheep are remarkably fond of all sorts of cabbages, and they are also very serviceable for feeding horses and hogs; and afford good nourishment to all.

The duration of these plants is of great importance: for some of them continue sound through the winter; and during the months of March, April, and May. This renders them peculiarly valuable: for in these months the winter provision for cattle is mostly spent, and the grass is not then advanced so far as to supply them, often not till the middle of May; for which reason farmers are distressed for food for their cattle, during the whole month of April, and part of March and May.

The first set of experiments on cabbages of different kinds, being winter plants, sown in August, and transplanted the sixth of March from the seed-bed.

- N^o 1. The green borecole.
2. The long-sided cabbage.
3. The flat Dutch cabbage.
4. The great Scotch cabbage.
5. The Anjou colewort.
6. The Battersea cabbage.
7. The York cabbage.
8. The sugar-loaf cabbage.
9. The green Savoy cabbage.

The ground upon which these were planted out, had the preceding year produced turnips, and the year before that potatoes; and was twice ploughed for the cabbages, without any other preparation. These plants were horse-hoed the 25th of May; again in June, and the last time in August.

The horse-hoeings were performed with a small plough, drawn by two horses, one before the other. First turning a furrow from the row of cabbages of one ridge, and another furrow from the next contiguous ridge, both these furrows being turned into, and meeting in the interval between these ridges: the next hoeing turned the earth also from the plants, the plough going in the same tract as at the first hoeing, only deeper, and nearer to the rows: because at the first hoeing, the plough does not go deep enough, and near enough to the rows; which it should do as close to the rows as can be done, without tearing out the plants. The third hoeing turns all the earth out of the interval up to the plants, which compleats the ridges as they were at first. This is the manner in which he hoed one side of each of the two contiguous ridges. The other sides of the ridges were next hoed in the same manner.

This is called alternate hoeing; and is necessary in hoeing ridges, upon which there is, as here, only a single row of plants upon each ridge: for if they had a whole hoeing at once, viz. both sides of the ridges ploughed away at once from the plants, the plants standing upon a narrow slip of earth would be thrown down, in turning the second furrow, if that was done before the earth of the first furrow was returned to support the row. In hoeing close to the plants, some few leaves will be broken off by the plough, but in no proportion to so many as might be imagined.

“The expence, says he, of these several operations, depends upon the nature and condition of the land; from three to six shillings an acre. This stood me in five shillings and six-pence;” [which is nearly 3s. and 5d. per English acre.]

As some earth will remain in the intervals after the third hoeing, (called the heinting) that should also be thrown up

to the ridges on each side, and will require one bout, if done with the hoe-plough: but with a double board-plough, the henting may be thrown to the ridge at half a bout, or one furrow; which will throw it all up, and leave a clear open trench between every two ridges.

The produce of the nine kinds of cabbages from each ridge 630 feet long, and 5 feet wide, with their average, and extraordinary weight, all being winter plants, was as follows:

		distance in the rows.	weight per ridge.			average weight.	extra weight.	produce per plantat. acre.				produce per Eng. acre.				Duration.

																	To October and November.
																	December and January.
																	Middle of May.
																	February.

1. The first column of the above table shews the distance at which the cabbages were planted upon the ridges.

2. The weight of the cabbages upon a ridge of 630 feet long, and 5 feet broad.

3. The average weight of the cabbages upon each ridge.

4. The weight of the largest cabbages of each sort.

5. The weight of the Anjou coleworts, planted 4 feet distant in the rows, the average of 17 lb.

Ditto, 3 feet distant in the rows, average 16 $\frac{1}{2}$ lb.

6. Produce per plantation Irish acre.

Ditto, per English acre nearly.

7. Duration, or the time when each sort began to decay.

The duration of cabbages, or how long they continue sound, and without bursting or running to seed, is an important circumstance; and it appears, by comparing Mr. Baker's experiments with those related by Mr. Young, in his North Tour, that cabbages of the same kinds decay earlier in the season in Ireland than they do in England. The great Scotch cabbage in particular, which with Mr. Baker continued sound no longer than January, is of much longer duration in England, as appears in the following tables from Mr. Young, shewing the duration of this species of cabbage, as he was informed by the gentlemen who cultivated it at large in the fields, viz.

Spring sowing.

	Duration.
Mr. Middlemore,	April.
Mr. Lyfter,	Christmas.
Mr. Tucker,	end of March.
Mr. Ellerker,	end of April,
Mr. Smelt,	end of March.
Mr. Scroop,	beginning of May.

Summer sowing.

	Duration.
Mr. Tucker,	want cutting before Christmas.
Mr. Crowe,	May-day.

"Mr. Young," says Mr. Baker, "gives amazing accounts of the progress of cabbage-husbandry in England; and it seems to be universally agreed, that the cabbage answers all the purposes of maintaining and fattening horned cattle and sheep. The kind which seems to be in most general use is the Scotch; though the turnep-cabbage and borecole are not neglected.

"It appears that this Scotch cabbage is generally found with them to stand the winter. Some gentlemen informed Mr. Young, that they stand until April, and even May." I have just had the favour of a letter from Mr. Young, upon husbandry matters, dated the 12th of April, 1770, in answer to one I wrote him upon this subject, and he says—"As to the Scotch cabbage all my accounts ran that it lasts quite through April; and I have now letters by me, just received from Mr. Scroope and Mr. Dodsworth, that their present crop is in fine order, with but few black-caps among them. They are, as you observe, hard, but do not burst until long after their loose leaves are all dropped off, and their outward skin turned black."

"The long duration in England of the Scotch cabbage, would be to me surprising, did I not consider two

probable causes of accounting for it. In England the frosts begin in October and November, whereas in Ireland, those months and December generally afford mild weather, attended with rain, and scarce any frost until January, February, and March; and even then, in general insignificant, when compared with those of England, and particularly the northern parts, where the cabbage culture seems to be most adopted. Indeed I observe the like even in the wheat of Ireland: for in November and December it looks florid and healthy, even in poor grounds; but in January, February, even March, and sometimes in April, as this year, 1770, it falls off wonderfully, and looks sickly, except where the lands are rich and dry.

"However, there is yet another probable reason why the cabbage which I have for Scotch, may decay sooner than in England: mine, it is very likely, is not the true kind: and in truth I have thought them no other than the flat Dutch, because they appear to be the same. If we look at the table taken from Mr. Young, we see some of the gentlemen find theirs to decay as soon as mine; so that it is mighty likely these several gentlemen have not all the same species; because there the difference of climate cannot operate."

Mr. Baker had planted his cabbages upon five feet ridges, and the large sorts at two feet apart in the rows; but upon further experience found that these distances were greater than necessary, and that larger crops were to be obtained by planting them on four-foot ridges, and eighteen inches distance in the rows; and the smaller kinds at only one foot distance in the rows.

He likewise tried what crops could be obtained by sowing the seed for winter plants earlier than August; but found the inconveniency of early sowing: for in the year 1770, he sowed the seed of ten different sorts of cabbages for his winter crop, the 24th of July, which was attended with the two following ill consequences, viz.

1. The plants grew away so fast, that towards autumn they became much too large; and when he came to draw them up out of the seed-bed in the spring, 1771, to plant them in the full ground, he found that many of them had rotted in the shanks during the winter, and all of them were too long shanked. 2. Instead of spreading their leaves for cabbaging, as they should have done, towards June they shot up, and broke out in blossom, at least nine out of ten; and the few that did cabbage, were but small, none weighing above ten pounds; and they began to go off early in October: hence he draws the following conclusion:

"That cabbage-seeds for winter plants are not to be sown until August; and I shall add, as my opinion, not until between the 20th and 30th of that month."

"In the culture of the Anjou colewort, this year, 1771, I have been much more fortunate than in the sorts above-mentioned, and that from a lucky circumstance, viz. that in the summer 1770, I was attempting to raise the seed of this plant, for which I used to pay 40s. a pound. Had I bought the seed for autumn sowing in 1770, I should have been in the same situation with this, as I was with the preceding ones. Having saved about nine pounds of this seed, on the 29th of August I sowed about a pound of it: the spring was so dry that my transplanting was late, not until the 24th day of April. The land was thrown into four feet ridges, and in 1767 had produced potatoes, in 1768 turneps,

turneps, in 1769 turneps and cabbages, in 1770 under cabbages, and the part planted this year with Anjou, was the two preceding years under the same plants. This field contains a little above 6 $\frac{3}{4}$ acres; near one acre was planted with the Anjou, one with other cabbages, four acres of grafs, and the head-lands with potatoes and carrots. The Anjou was horse-hoed twice, in the usual manner.

"Eight horses were turned into this field, to feed upon the grafs: they began immediately to feed upon the Anjou colewort with surprising avidity. This was an unexpected application of the crop, and lost me the opportunity of weighing one of the rows, as I intended. Upon the most moderate and equal calculation we could make, we apprehended the horses were plentifully maintained three weeks upon this crop, which, at five pence per horse, amounts to 3l. 10s. I do not offer this calculation as being perfectly exact, though I believe it be within, rather than over the truth.

"In a fortnight after the horses were brought home, I turned in forty-five sheep, three young calves, and a fine young bull, which I have: these remained here in the following order:

December 18th, turned in,		
January 9th, sold 13	990 sheep a day.	
16th, sold 16	224 ditto.	
23d, sold 16	112 ditto.	
45	1326	

"These 45 sheep were not only maintained, but really much mended in flesh and tallow upon this pasture; equal in point of time to keeping 1326 for a day. If we value this at an half-penny per head, the pasturage amounts to 2l. 16s. 3d.

"Besides this crop of Anjou colewort, there was about an acre of summer cabbages, which from late planting, were nothing: I leave them to counterbalance for the food of the bull and three calves. By calculating from the improvement in the value of the sheep, the profit made upon them appears to be 3l. 3s. from their feeding upon this crop; which shews that I have not over-valued the pasture of the sheep, at an halfpenny a day.

"The accounts being united, will stand thus:

Maintaining 8 horses three weeks,	3	10	0
Maintaining the sheep as before mentioned,	2	15	3
	£	6	5 3

"Thus I think it comes out pretty clearly, that the Anjou colewort is worth at least six pounds an acre: a produce by no means contemptible, when we consider the cheapness of the culture; which, after the ground has been properly manured for potatoes, cannot amount to forty shillings, including rent, &c. But let no man imagine he can cultivate this or any other of the cabbage tribe, without liberal manuring; the most profitable method of doing which is certainly by making potatoes the crop in preparation.

"Although the experiment before us, has not been attended with all that accuracy which I am fond of adhering to in my pursuits; yet it affords some important facts which may be depended upon. I shall collect them in one view.

1. That horses will eat this plant, that they are fond of, and thrive upon it.
2. That sheep thrive very fast upon it, and are fond of it to excess.
3. That it affords them fine shelter, and food perfectly free from any kind of dirt.
4. That as fine plants may be raised from seed carefully saved in Ireland as from imported seed, I used to pay 40 shillings a pound for it: in 1774, I hope to supply the public at 4 or 5 shillings a pound; probably less.
5. That this plant may be planted upon the same ground for three years in succession, without intermission, even after producing turneps; being previously prepared by potatoes.
6. That ridges four feet wide seem to be a sufficient distance; as this, the third crop, upon the same ground, was a very noble one.
7. That Anjou coleworts will, in the winter, pay more than three-pence halfpenny a week per head for pasturing sheep.

"It was truly a pleasing sight to see the sheep dispersed through these lofty greens; the white and green made a variation every man must admire: half an hour's feeding the animals had found sufficient; then they marched, as it were by mutual consent, to the clean grafs, and all lay down in a cluster for an hour or two at a time; then rose again, stretched themselves, and all marched away to their food; and thus they went on, day after day, until at last, I am satisfied, they lay down half the day: a strong indication of their fattening fast.

"This plant grew, with Mr. Baker, six and eight feet high: sheep reach the leaves to about the height of four feet, and the horses eat the upper part of them. He observes, that Mr. Young, in his fourth volume, p. 202. says, "Anjou is good for nothing with Mr. Turner and Mr. Scroop. Savoy, I presume the green Savoy cabbage, this in the same trial, in rows four feet asunder, by one foot in the rows, came to five pounds at an average, or twenty-four tons per acre, which is a considerable produce. Cattle like them very well; but they would not stand the winter."

"Here we find," says Mr. Baker, the account which these two gentlemen gave Mr. Young of these plants, appears to be diametrically opposite to my success in the culture of them. With them "the Anjou was good for nothing;" and the Savoy "would not stand the winter." The latter I cannot account for: the former I think fully in my power, by experiments this year. I can be almost certain, that the Anjou in their trials was sown in the spring, and set in June. In that culture, I can now inform the public, the Anjou are not so luxuriant as I expected they would have been. The weight of the Anjou has been already stated: its duration for plentiful pasture continues until the middle of May; and the Savoy until February expired. I used all I had by that time, though I believe they would have stood longer.

"A table of the duration of winter plants, sown in August:

The class first in decay.

Duration.

The long-sided,	} October and November.
The Battersea,	
The York,	
The sugar-loaf,	

The second class.

The flat Dutch,	} December and January.
The Scotch,	

The third class.

The Anjou colewort, middle of May.

The green Savoy, end of February, or later. See above.

"Hogs eat raw cabbages greedily, and thrive upon them."

The seed of the Anjou was sent by the marquis of Turbilly to the London Society of Arts, who distributed it to many of the members; by which means this plant was raised in several parts of England: but it does not appear with what success it was cultivated in England; except what Mr. Young mentions as above. Mr. Baker appears to have been the first who cultivated it with accuracy and success. The marquis calls it the Anjou cabbage; Mr. Baker, the Anjou colewort, because it grows with open leaves, and does not cabbage. It appears to be a very valuable plant, with respect to the great quantity of food it produces for sheep and horses; and especially for its long duration, even to the middle of May, if the seed is sown in August, and transplanted from the seed-bed into the full ground in June: add to this the excellent shelter these tall plants afford to sheep.

Mr. Baker found, that from 16 to 20 pounds of seed was the proper quantity to sow in the seed-bed, to furnish plants of the larger kinds of cabbages, sufficient for an Irish plantation acre; which is from 10 to about 12 $\frac{1}{2}$ pounds to furnish plants for an English acre. The seed of borecole being smaller than most of the others, from 8 to 10 pounds of that will be enough for an English acre. The seed of all the cabbages should be sown pretty thin in the seed-bed; allowing between two and three perches of ground well prepared, to every pound of seed. The best way

way is to sow the seed in drills : Mr. Baker says, that where handy active men are employed, three men will easily transplant an Irish acre a day, which is about an acre and a half English.

“ The second set of experiments made in 1769 upon the cabbage husbandry, being the spring or summer culture.

The kinds were as follow :

	Distance.		Average.		Extra.		Produce of an Irish acre.					Produce per English acre.			
	inches.	feet.	lb.	oz.	lb.	oz.	Tons.	C.	qr.	lb.	oz.	Tons.	C.	qr.	lb.
N ^o 1. The green borecole,	21 $\frac{1}{4}$	by 5	5	6 $\frac{1}{2}$	8	0	19	4	0	17	1	12	0	0	0
2. Great Scotch cabbage,	23 $\frac{1}{2}$	by 5	6	13	9	0	21	16	3	11	6	13	12	2	0
3. Anjou colewort,	2 feet	by 5	5	9	0	0	17	15	2	17	14	11	2	0	0
4. Chos du Milan,	2 feet	by 5	4	8	0	0	14	8	2	7	0	9	0	0	0
5. Turnep-cabbage,	18 in.	by 5	5	0	0	0	21	00	0	0	0	13	2	2	0
6. Jerufalem colewort,	2 feet	by 3	7	0	14	8	36	15	0	0	0	22	10	0	0
	2 feet	by 5	7	0			22	1	0	0	0	13	6	0	0
7. White brocoli, 2d sowing,	2 feet	by 5	4	1	0	0	13	1	2	0	3	8	2	2	0
8. Purple brocoli, ditto,	2 feet	by 5	3	15	0	0	12	12	3	11	13	7	17	2	0
9. Green brocoli, ditto,	2 feet	by 5	3	8	0	0	11	3	3	4	8	6	17	2	0
10. Red pickling cabbage,	23 $\frac{1}{2}$ in.	by 5	6	0	9	0	19	7	0	0	0	12	1	3	0

“ The seed of these was sown the 10th of March, except N^o. 6, sown the 24th of March : likewise a second sowing of No. 7, 8, and 9.

“ Five plantation acres were prepared for these plants : the land was ploughed in November, again in April, and harrowed down ; and the latter end of May it was thrown into five. feet ridges, at three bouts of the plough. The 17th of June the land was manured, by laying the manure upon every second ridge alternately, and throwing it equally into the two contiguous furrows ; and immediately ploughed in, by turning the ridges into the furrows, by which means the new ridges stood over the dung, as in a hot-bed.”

“ The 21st and 14th of June there was fine rain, and three plantation acres were planted from the seed beds, with the plants, N^o 1, 2, 3, 4, 5 and 10. Mr. Baker finding the common dibbers made slow work, made dibbers of iron eighteen inches long, and seven pounds weight ; which made quick work, preferable to making out furrows in the ground with the plough, and much more exact. “ I can, says he, put out an acre of plants, for at least half, if not a fourth of the expence of transplanting the plants in furrows made by the plough ; and straighter, the top of the ridge being a guide to transplant them in a regular line, which is necessary where plants are to be horse-hoed : another advantage is, that the ridges, when planted in furrows made by the plough, cannot be raised for the reception of the plants, and have not that depth of well prepared mould for the roots to extend it, as when the ridges are raised hand-somely : suppose the staple that our plough works in to be nine inches, by throwing it up into these ridges, I make it eighteen : if the staple is but six inches deep by raising the ridges, they may still be made near eighteen, by widening the mould-board of the plough. The benefit of this to the plants must be obvious to every man.”

But here it is to be noted, that Mr. Baker said this in the year 1769, when he made his ridges for cabbages five feet broad, which would admit of being raised high : but if the ridges were made considerably narrower, and the staple was but six inches deep, by raising narrow ridges upon such staple to the height of near eighteen inches, so much of the mould would be raised into the crown of the ridges, that there would not be enough of it left on the sides to be horse-hoed ; which is a necessary consideration in culture of plants by the horse-hoe.

“ I have already informed the reader, that the Scotch is the kind of cabbage in most general cultivation in England, for the purpose of the farmer and grazier. According to the information which Mr. Young obtained, some gentlemen have had above 50 tons upon an English acre, (and some few as low as 15 tons) as appears by the following table from Mr. Young :

On clays and strong loams.	Soil.	Average weight. lb.	Distance.	Rooms to each plant.
Mr. Turner 39	clay	15	2 ft. by 4	8 sq. feet.
Mr. Crowe 35				
Mr. Scroop 37				
Earl of Darlington 40				
Mr. Dixon 48				
Average 39 Tons.				
On rich deep light loam.	rich loam	20	2 & 2 $\frac{1}{2}$ by 4	8 & 10 feet.
Mr. Tucker 44				
On inferior soils.	red sand	14	18 in. by 4	6 sq. feet.
Mr. Midlbmore 54				
Mr. Lyller 27				
Mr. Smeit 18				
Mr. Scroop, Dalton 21	sandy gravel	7 $\frac{1}{2}$	2 by 4	8 do.
Average 39 tons.

								if taken up as directed, in Feb. will keep sound till June, or later, if desired.

Considerations upon Borecole and some other Plants, dropping off in the Winter the Leaves of the Summer Growth.

Under this head I shall only consider such of our plants as stand the winter throughout ; and of those only such as we have seen are most profitable in the course of our experiments, and therefore in this place I have only to take notice of the borecole, the Anjou colewort, the turnep cabbage, and the red cabbage ; these I think are the only plants which stand until spring, and cast their leaves of the summer growth.

The borecole I have already said stands the winter admirably ; and as it casts the summer leaves in December and January, proceeds in vegetation, and produces another succession of leaves, not so large, but infinitely more in number. With me all the summer leaves dropped off, and consequently were lost ; but that need not be the case with other cultivators. I thought it necessary for the information and conviction of the public, to let this whole plantation stand, without any diminution but the natural ; I still think, as I did in the year 1764, that the most advantageous way of using this plant, would be by turning their sheep into the field, as described in my report for that year. By that means the summer leaves will be turned to profit, which cannot answer any other way : for the pulling and bringing them home would be too expensive, because it must be all hand work, and men's carriage, to the head lands ; as no carriage can be admitted amongst the plants, the intervals being too narrow.

The Anjou colewort casts its summer leaves in November and December, but will be handsomely furnished again by the winter growth against the spring. The same objections hold good, with respect to making use of the summer leaves, by carrying them off, as I have just offered to the borecole ; and this plant should also be pastured with sheep, to prevent the loss of the summer growth. The extraordinary height of this plant (viz. the winter plants) might be some impediment to its being pastured by sheep ; as I suppose they cannot reach above four feet high, and my plants are now seven or eight feet : but I observed that the bulk of the summer leaves which fell off in the winter, were chiefly those about four feet up the stem : those above that height seem in general to stand the winter, and are food for horses above where the sheep can reach. Next to plentiful pasture, I heard the graziers always talk of good shelter. In plantations of borecole, Anjou colewort, and Jerufalem colewort, we have a profusion of pasture, and shelter beyond conception, for sheep and lambs, and we have

have them both at a season when they are most wanting, and when they can scarcely be had spontaneously upon any grounds, and more particularly on pasture.

"To direct the choice of species and seasons for the advantageous progress of the cabbage husbandry, I have added the following

Table of Successions.

Species.	Sown.	Planted.	In use.	Duration.
The long sided cabbage	In August	In March	In August	till November
—flat Dutch do.	August	March	December and January	January
—Scotch do.	August	March	December and January	January
—Anjou colewort	August	March	December and May	May
—green borecole	March	June	December and May	May
—turnep cabbage	March	June	February and June	June
—Jerusalem colewort	March	June	December and May	May

By this disposition of our cabbage crops, in sufficient quantities, we should have them, from the time of our grass and clover being diminished, until we can have those two resources again in plenty. Surely no consideration can so much recommend this husbandry.

The swine have had nothing all the winter but cabbages of different kinds, and they have done very well with that food, except such as were not bred to it; those do not keep themselves in so good order with it as the others. I am aware that it will be a matter of some admiration to many, that I keep such a quantity of swine, as I have frequently had occasion to mention in this report: (83 head, viz. four or five very large ones, some middling, and some small: upon the whole, if they had been all fat, I apprehend they would all have weighed upon an average three quarters of an hundred a piece.) My reasons are principally, that of making great quantities of dung, to which this animal wonderfully contributes, and the obtaining large quantities of meat at a cheap rate, for a very large family, as mine is.

The turnep cabbage, and red cabbage, also cast their external leaves the beginning of winter, and should be taken off for the cattle before they decay; but should not be fed off by sheep, because they will fall upon and wound the body of the cabbage, and do more damage than the value of the loose leaves.

The turnep-rooted cabbage is a spring plant, very hardy, and continues found through the winter and spring. The merit of this plant is in the root, the tops being very small. The objection to it is the labour in getting up the roots, which cannot be done without a mattock or a very strong three pronged fork. They are juicy, but not watry, have an agreeable flavour, and the black cattle are fond of them; but are so hard they cannot eat them but with difficulty; and Mr. Baker found they made the cattle's mouths bleed, and therefore when given to them, the roots should be first washed and chopped in pieces; and then they may be eaten by black cattle or sheep; they produce a great quantity of roots.

Mr. Baker apprehending that the distances he at first allowed to his cabbage plants, (of 5 feet ridges, and 2 feet or more in the rows) were greater than necessary, and that greater crops might be obtained by planting them closer, viz. the ridges to be only four feet broad, and the plants according to their respective sizes and luxuriancy, to be set in the rows, from one foot to two feet or more, gives the following table, of the most proper distances of the several sorts, to produce the greatest crops, from his observations and experience of the growth of each sort, as follows:

The Table of Distances for the Cabbage-Husbandry.

	Season.	Distance I have used.	Distance I venture to recommend.
The long sided cabbage	winter plants	2 feet by 5 feet	2 feet by 4 feet, or 18 inches by 4 feet
The flat Dutch cabbage	ditto.	2 5	2 feet by 4 feet, or 18 inches by 4 feet
Ditto	spring plants	2 5	18 inches by 4 feet
The Scotch cabbage	winter plants	2 5	2 feet by 4 feet, or 18 inches by 4 feet
Ditto	spring plants	3½ 5	18 inches by 4 feet
The Anjou colewort	winter plants	4 5	} 2 feet by 5 feet
Ditto	ditto.	3 5	
Ditto	spring plants	2 5	
The green borecole	ditto.	21¼ in. by 5	1 foot by 4 feet
The turnep cabbage	ditto.	18 5	1 foot by 4 feet
The Jerusalem colewort	ditto.	2 3	18 inches by 4 feet

At these distances, more plants will be required, and the expence of transplanting them will be something greater; but these are trifling in comparison with the increased products per acre.

Mr. Baker observing that a horse employed to draw the cabbages home, eat them very freely, ordered several other horses, one after another, to draw home the cabbages, "and they all eat the borecole most eagerly. But what is more remarkable, the horse which has been chiefly employed in this business, is in better order than any other draught horse I have; and I find (from the nature of his employment, often requiring him in the cabbage field, when the horses get their corn) he has been deprived of his share of corn.

"These events have determined me to try an horse next winter with the borecole and hay, and another with the borecole and corn. It may be imagined that the borecole will gripe the horses; I cannot tell; but the plant, as I before said, is very dry and warm. Should it be found to answer the purpose of maintaining the farmer's horses with a small allowance of hay or corn, or even both, it will be inestimable indeed.

"With pleasure I discover that the cabbage husbandry is making great progress through the kingdom; but I receive so many letters, complaining of the seeds, not only being mixed, but so often, that not a grain of the kind they had been purchased for was among them; which, added to

the prices they were sold at, is a great discouragement to the progress of this husbandry: I have therefore determined to raise the seeds myself, or all such kinds as I have, or shall find most advantageous to the farmer's purposes. But as all the cabbage tribe are apt to engender, and produce bastard kinds, I cannot raise many sorts in a season, to have them perfect, and therefore I cannot immediately furnish every kind. However, I have made some beginning, and now have the following sorts ready to supply such as may call.

Green borecole, a single pound 4 shillings; seven pounds at two shillings and 8 pence, per pound. } I used to pay 10 shil. a pound.
 Reynolds's turnep-rooted cabbage, a single pound 4 shillings; seven pounds at 2 shillings and 8 pence per pound. } Ditto 16 shil.
 Jerusalem colewort, a single pound 4 shillings; seven pound at 2 shillings and 8 pence per pound. } Ditto 16 shil.
 Anjou colewort, a single pound 8 shillings; seven pounds at 5 shillings 4 pence per pound. } Ditto 40 shil.

"By this reduction of prices, I hope the public will see manifestly that I have not any profit in view by this object; all I aim at is, to indemnify my expence, and to promote the cabbage-husbandry. If the demand shall be such as to

defray the expences, I do not despair of reducing the prices still lower, since it is not the price I look at to indemnify me, but the quantity sold. Mr. Marshall, in his *Minutes of Agriculture*, says, that he found cabbages of very great use to the yard-hogs, particularly the suckling sows."

CADDOW, a name given to the jack-daw, in some of the northern counties of England.

CADMA, the least of the pigs which a sow has at one farrowing; for they have generally one which is remarkably less than the rest.

CALF, the young of a cow.

There are two ways of breeding those calves you design to rear; the one is to let them run with the dam all the year, which is the common way used in the cheap breeding countries, which they reckon makes the best cattle; and the other way is, to take them from the dams after they have sucked about a fortnight: then they teach them to drink flet or skimmed milk, which they make just warm for them, it being very dangerous to give it them too hot. The best time for weaning of calves is from January to May. Let your calves have milk for about twelve weeks; only a fortnight before you wean them from milk, let water be mixed with the milk; and after your calf hath drank milk about a month, take some of the freshest, sweetest hay you have, and put little wisps of it into some cleft-sticks, which place so as the calf may easily come at them to learn to eat; and after Lady-day, when the weather is fair, turn your calves to grafs, taking them in a few nights at first, giving them milk and water, and sometimes giving the same to them in a pail in the field, till you find they are able to feed themselves, so as not to desire it: but by no means let your grafs be too rank, but short and sweet, that they may get it with some labour. All wean their calves at grafs; for if you wean them in the house with hay and water, it is apt to make them big-bellied, and to rot; and when you have resolved which of the males to keep for bulls, let the others be gelt for oxen, which the sooner you do the better: when they are between ten or twenty days old, is the best time and least dangerous.

In Hertfordshire, Essex, and most places near London, they commonly fat all their calves for the butcher, because they have there a good market for them, and the lands are not so profitable to breed on as in cheaper counties; a good calf there often selling for as much as a good heifer, especially if they are very fat and white, which they take a great deal of care to make them. Their way of doing this, is by keeping them clean, giving them fresh litter every day, which they lay upon their old litter; for they clear out their coops but two or three times in a year, and most commonly at a time when they have no calves in them: they constantly also let them have a large chalk-stone or two to lick, which they bore a hole through, and hang up by a string in a corner of the coop, which prevents their fouling it with dung and urine. They also observe to fet their coops where they may have as little sun come to them as they can, that they be not made close and stifling, and that they stand a yard above the ground, that the urine may run from them: and to make them white, they often let them blood when they are about a month old, and a little before they kill them; and because they are often loose, they do not let them suck their fill; but instead of it they sometimes give them chalk scraped into milk, which they pour down with a horn; also salt and water; and sometimes they cold bathe them, and give them bole-ammoniac and chalk, which they moisten with milk, and make it into balls, and give it them. If a cow will not let a strange calf suck her, rub both hers and the calf's nose with a little brandy. *Mortimer's Husbandry*, vol. I. p. 228.

A young calf is left with its dam the first five or six days, that it may be kept always warm, and suck whenever it pleases: but if in those five or six days it grows and gathers strength, there is a necessity for making a separation, as he would exhaust the cow if left always with her. Sucking two or three times a day will now be sufficient. If you intend to fatten him speedily, and at the same time, render his flesh fine and delicate, let him have every day raw eggs, boiled milk, and the crumbs of bread: by this means the flesh, at the end of four or five weeks will be excellent. Calves, therefore, intended for the butcher should not suck above thirty or forty days; but those designed for the dam for two months at least; as the more they suck, the stronger and larger they will prove. The best for bringing up are those calved in the months of April, May, and June. It is seldom that those which come later acquire sufficient vigour

to support them during the inclemency of the following winter; the cold causing them to droop, and many of them to die. Thus calves designed for keeping should be weaned at two, three, or four months; but before taking them totally from the milk, a little good grafs, or chopped hay, should be given them, that they may become accustomed to such aliment; for when they are to be entirely separated from their dam, they must never be suffered to come near her either in the stall or pasture, whither they should be sent every day, and remain there, during the summer, from morning to evening; but at the setting in of the cold weather in autumn, they must not be let out till late in the morning, and brought back early in the evening. And as the pinching cold of winter will be extremely detrimental to them, they should be kept very warm in a cow-house, and well supplied with water; fainfoin, lucern, &c. should be mixed with their common hay. They must be let out only in warm weather. A great deal of care is necessary to bring them through the first winter, which is the most dangerous period of their lives; for they will acquire so much strength during the following summer, that they will have nothing to fear from the cold of a second winter. *Buffon's Histoire Naturelle*, tom. IV.

Mr. Marshall says that he is clearly of opinion, that to suckle calves, in general, after they are ten weeks old, is bad management; for his account in this respect is uniform; those of nine or ten having paid as much a week as those of twelve or thirteen; and although a calf of six weeks old, may suck nearly as much milk as a calf of twelve weeks old; yet the first month or five weeks, the quantity is considerably less, and this advantage of their infancy is doubly as valuable to nine, as it is to twelve weeks.

The same gentleman in his *Rural Economy of Yorkshire* says "There is a practice pretty common in this neighbourhood, though not general, which merits notice from its singularity rather than from its excellency. It is the calf never sucks the dam! which from the time of her calving, is milked into a pail, and the warm milk given immediately to the calf; which never having had the teat, soon learns to drink. The chief reason given for this practice, is that the cow does not pine after her calf, so much at least, as when it is permitted to suck her. For rearing calves, no material objection is to be made to this method, except that of additional labour, and that calves do not fat so kindly with the pail as with the cow: nor is it probably so good for the udder of the cow.

Mr. Marshall in the same work says "The time of rearing a calf is Candlemas to Old Lady Day. A raw nose, that is a white muzzle, with nostrils red on the inside, is considered as a bad mark, portending a tender beast; and on the contrary a black or brown muzzle, with dark-coloured nostrils, is esteemed a sign of hardiness. A calf entirely white is generally rejected, under a notion that white cattle are of a tender nature; that they are peculiarly subject to lousiness; and that they are disliked by their associates! The finest ox I ever knew of the Holdernefs breed was white. The finest ox I ever saw of the Tees-water breed was white. One of the finest cows now in the vale is white. Nevertheless, valuable calves are annually sent to the butcher, merely because they are all white. The smallest speck of colouring, even the tip of an ear, red or black, saves them from proscription: under a notion, no doubt, that it hardens their nature; defends them from lice; and renders them acceptable to their companions: a vulgar error, which is not confined to this district; but which ought, in my opinion, to be universally exploded. Oxen in this country (as probably in others) are peculiarly subject to a stoppage in the intestines; owing, it is believed, to the "blood strings" of the testicles being left in the body at the time of gelding. The fact seems to be, that the disorder is generally caused by a link of the intestines being thrown, (in playing it is supposed) across a ligature situated near the anus; and the cure is radically effected by breaking this ligature: an operation which is not unfrequently performed. If the ligature be really a string of the testicle, indexterously left in the calf, much caution is requisite in the operation of gelding. An experienced cutter performed it thus: having extricated the testicle, and cut the seminal cord, he forced his finger and thumb upward, as it were into the body of the calf, (which stood on its legs during the operation) drawing the "blood string" twelve or fourteen inches long: the point of it appearing not abrupt, as if broken off, but fine as a thread, as if wholly extracted. Their treatment as before-mentioned differs in the practice of

of different individuals. In an instance which, perhaps, may be considered as a fair specimen, the treatment is this:—The calf never sucks its dam; but has her milk warm from the teat given to it twice a day in a pail; from the time of calving until it be a fortnight or three weeks old. At that age the calves begin to have half new milk and half skim-milk, boiled (which is thought to be more “nourishing” than raw milk) for about three weeks longer: they are then put to all skim-milk, or to milk and water, with perhaps a little oat-meal or wheat flour strewed over it; and with hay, in the early part of the season; or grass, as soon as spring and the warm weather sets in. Sometimes a small quantity of linseed jelly is mixt with thin milk and water, and is found of great service; making their skins remarkably sleek and silky. If too much be used, it is liable to make them scour. In the latter end of May or the beginning of June, according to the time of their being dropped; they are turned away to grass and water only, for the summer.

The same gentleman in his Rural Economy of Norfolk says “That he paid more than common attention to the rearing calves in this district, not only as being a primary object in the East-Norfolk system, but because the practice here is, in many respects, peculiar to this country. Some farmers bring up all the year round; rearing every calf he has dropt. Others rear in winter only; fattening his summer calves for the ped-markets; or at a distance from them, for the butcher. Norfolk farmers, in general, begin early in winter to rear their calves; some so early as Michaelmas; in general, if their cows come in before Christmas: not only as being fully aware of the advantage of rearing early, but in order that they may rear as many of their own calves as possible; drove calves being always hazardous and sometimes scarce. No distinction is made as to sex: males and females are equally objects of rearing, and are both occasionally subject to castration, it being a prevailing custom to spay all heifers intended to be fatted at three-year old; but such as are intended to be finished at two-year-old are, I believe, pretty generally left “open:” as are, of course, such as are intended for the dairy.

There are two reasons for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution may lie more quietly—are kept from roving—at the time of fattening. This may be one reason why spayed heifers are thought to fat more kindly at three-year-old, and to be better fleshed, than open heifers.

The method of treatment depends in some measure on the time of rearing: the winter calves require more milk than the later-dropt ones do.

The general treatment of a calf dropt at Christmas may be said to be this: sucks twice a day, the first fortnight: has the pail twice a day, for the next month or six weeks. and once a day, for a month or six weeks longer:—with hay in a rack, and turneps in a manger; and, sometimes, with oats and bran among the turneps; which last, after a calf has taken freely to them, serves as both meat and drink.

In this consists the chief peculiarity of the Norfolk method of rearing calves; which may be said to be with milk and turneps: the last a species of food, which, in every other part of the kingdom, is, I believe, entirely neglected, or unthought of.

As soon as the weather gets warm enough, the calves are turned out, in the day, among the fattening bullocks, or on to a patch of turneps, or upon a piece of wheat, or a sward grass-piece, and housed again at night: until, the days growing long, and the nights warm, and the clover and dandelion have risen to a full bite, they are turned out altogether; and continue to have the first bite of every thing, which is good and palatable to them, throughout the summer.

This may be called the general treatment of calves dropt at Christmas; but the management of no two farmers are exactly the same.

The same intelligent gentleman in his Rural Economy of Gloucestershire, says, “The season of weaning lasts from Christmas to Lady Day: seldom longer: late-weaned calves interfere with the dairy.

The method of rearing is pretty uniform: at least in the outline. The calf is usually taken from the cow at two or three days old, and put to heated milk. The degree of heat, however, varies. In the practice of the first breeder in the vale, the milk was given to the calves scalding hot! as hot as the dairy-girl could bear her hand in it. The lips

of the calves were not unfrequently injured by it. His reasons for this practice were, that the heat of the milk prevented the calves from scouring; made them thrive; and enabled him to put his rearing calves to skim milk, immediately from their being taken from the cow; at two or three days old. They never tasted “best milk” after they were taken from their teat at that age.

This is an interesting instance of practice; and merits a few moment’s reflection. Nature has evidently prepared milk of a peculiar quantity for the infant calf; and this milk is useless in the dairy: it is therefore doubly good management to suffer the calf to remain at the teat, until the milk becomes useful in the dairy; which it usually does in two or three days. But although it becomes, to general appearance, similar to that of a cow which has been longer in milk, it is highly probable, that it is still singularly adapted to the yet infant state of the calf. In the suckling-houses, round the metropolis, it is well understood, that putting a young calf to a cow, which is old in milk, will throw it into a scouring. It, no doubt, requires a degree of correction to render it fully acceptable to the stomach of the calf, at so early an age: and, if we may venture to judge from this instance of practice, sufficiently authenticated, scalding the milk, very highly, gives it the due correction.

Besides the scalded milk, this judicious manager allowed his calves split beans, oats, and cut hay. When they took to eat these freely, water was, by degrees, added to the milk.

In the spring they were turned into a large well herbage ground; allowing them so good a pasture, that it was generally mown after them: and during the whole of the first summer, they had the first bite wherever they went.

“Calf-stages,” or calf-pens of this district is of an admirable construction: extremely simple; yet singularly well adapted to its intention. Young calves,—fattening calves more especially—require to be kept narrowly confined: quietness is, in a degree, essential to their thriving. A loose pen, or a long halter, gives freedom to their natural fears, and a loose to their playfulness. Cleanliness, and a due degree of warmth, are likewise requisite in the right management of calves.

A stage which holds seven, or occasionally eight calves, is of the following description.—The house or roomstead, in which it is placed, measures twelve feet by eight. Four feet of its width are occupied by the stage;—and one foot by a trough placed on its front; leaving three feet as a gangway; into the middle of which the door opens. The floor of the stage is formed of laths, about two inches square, lying lengthway of the stage, and one inch asunder. The front fence is of staves, an inch and a half diameter, nine inches from middle to middle, and three feet high: entered at the bottom into the front bearer of the floor; (from which cross joists pass into the back wall) and steadied at the top by a rail; which, as well as the bottom piece, is entered at each end into the end wall. The holes in the upper rail are wide enough to permit the staves to be lifted up and taken out; to give admission to the calves: one of which is fastened to every second staff; by means of two rings of iron joined by a swivel; one ring playing upon the staff, the other receiving a broad leathern collar, buckled round the neck of the calf. The trough is for barley-meal, chalk, &c. and to rest the pails on. Two calves drink out of one pail; putting their heads through between the staves. The height of the floor of the stage from the floor of the room is about one foot. It is thought to be wrong to hang it higher, lest, by the wind drawing under it, the calves should be too cold in severe weather: this, however, might be easily prevented by litter, or long strawy dung thrust beneath it.

It is observable, that these stages are fit only for calves, which are fed with the pail; not for calves which suck the cow.

Fattening calves are here kept on the stages until they are sold: rearing calves, until they be three weeks or a month old; or until they begin to pick a little hay; when they are removed to a rack, and are allowed greater freedom.

The fattening of calves is here a subordinate object of the dairy; the late-dropt calves are an encumbrance on cheese-making, the primary object, and are of course got rid of as soon as possible. One singularity of management, however requires to be noticed. Calves, whether for rearing or fattening, are seldom suffered to suck more than two or three days; sometimes they are put to the pail, as soon as they are dropt; the milk being, I believe, pretty universally

tally passed through the kettle; and given to the calves warmer than it comes from the cow. On the increased heat of the milk, the advantage of this unnatural mode of fattening is here thought principally to hinge.

In North Wiltshire, Mr. Marshall says, "The calves, which are not reared, are fatted by sucking, for the London market, mostly sent up dead. The common age of butchering six or seven weeks. Here, instead of calf-pens or stages, calf-stalls are in use. Each calf has its separate stall, about two feet wide and four feet long; just room enough to lie down; on a platform of boards or laths; with a range of troughs before their heads: with which, in this case, they stand towards the wall; tied up short, as aged cattle; a plan which might well be adopted by the sucking farmers about the metropolis. It has many advantages over the pens there in use."

The desire of profiting by the milk of the cow, is often the cause of the calf's being too early weaned. A month or two more, in short, the time required by nature, would strengthen it in its youth; it would grow more successfully, and, in time, fetch a profit with good interest. But this is hardly done any where. No sooner is it believed that it can subsist without the mother's milk, than the farmer thinks he gains a great deal by weaning it: ill fed, and infirm, it grows at best to be a sorry bull, or feeble bullock, from which little profit, and much less service, can be expected.

Ignorance and want of reflection form the principal source of this abuse! People do not know, or do not reflect, that the vital flame, inclosed in the heart of a newborn animal, must be cherished and augmented; that it attracts and is nourished by that contained in the milk; that this vital flame, weak at first, would scarce have power to separate the auxiliary fire from the milky particles with which it is incorporated, if milk was a less delicate substance than nature hath formed it for this first service; but in proportion as the vital fire acquires force, the milk grows thick, because its grosser particles are destined for forming and consolidating the body of the animal. When the vital flame is arrived at such a degree, as to be superior to the succours which the milk can afford, nature excites the animal to seek a more solid nourishment, and then, but not before, is the time for weaning it. For, by anticipating that time, you run the risque of leaving the animal imperfect in its interior parts: the aliment which is administered being above its strength, it cannot perform a perfect digestion, and the nourishment it receives is much the less; because, in all natural bodies, the strongest juices, and the most efficacious qualities are always mixed, and, as it were, blended with the hardest particles. Hence it happens, that a sickly animal does not derive from the same food so much nourishment as an animal in health. Indeed, the vital flame, too much employed in resisting the attacks of the corrupted humours, hath not force enough to extract from the aliment the necessary auxiliary fire it contains. Besides, the food being only in a part dissolved, passes away in the excrements, and forms only a thin inefficient manure.

As therefore we may be assured, that by weaning a calf too early, it will continue infirm and of a small value, so by leaving it with its mother, as long as its constitution requires, we may expect it will become strong and vigorous; and by following this method, we can hardly fail of raising a breed of cattle, that will redound both to the honour and profit of the farmer.

Young calves are apt to be attacked by insects, which disturb and torment them, and, at the same time, prevent their fattening. In order to preserve them from these insects, and even cure them when they are attacked, it will be proper to prepare an ointment of melted hogs-lard and quick-silver, well rubbed together in a marble or iron mortar. Spread this ointment upon a lincloth, which wrap up in three folds, and slitch it for a collar to the calves. It will not only cure them, but also disperse the insects.

There is no better nourishment for young calves, than vetches soaked in the water till they swell; but observe to steep no more than will serve them for once; because when they continue moist for any considerable time, they are apt to grow sour, and would then do them more harm than good. *Journal Oeconomique*.

Mr. Young, in vol. I. of his *Annals of Agriculture*, p. 297. recommends skim-milk with flax-jelly as proper nourishment for rearing calves, better than skim-milk alone.

In vol. III. p. 380. Mr. Young introduces a method practised in Cornwall, wherein shelled oats made an excellent gruel to mix with skim-milk, and his correspondent describes the method as follows: "In the first place, they are taken from the cow, from the fourth to the sixth day; then they are given raw milk from six to ten days or a fortnight; then skim-milk and gruel, from three quarts to four, in the morning, and the same again in the evening: a mixture of gruel is thought better than the milk alone: lately they have given their common family broth, which is thought as good, or better than the gruel, as the calves prove exceedingly well upon it, and the flavour of the salted provisions is thought to strengthen their bowels: the proportion of gruel or broth is about one-third of the quantity given: a little fine hay is set before them, which they soon begin to eat. As to continuing their meat when at grass, it depends on their age, the quantity of milk on hand, and the goodness and quantity of the grass: it is thought, after they are ten or fourteen weeks old, they will need no more milk, and for some time before, it is reduced to once a day. The disorder which most generally attends them, is what they call the *skat* or *scum* (a looseness) for which they mix a raw egg or two with their meat, stirring it well just as it is given, which is continued for several days; some grate acorns, and give them with their milk to stop the disorder; and where it has been obstinate, Bostock's cordial has been given with success. In Devonshire the method made use of for rearing calves, is by a mixture of scalded or skimmed milk and oatmeal, about two thirds of the former, and one of the latter, and found to answer extremely well; but they are not weaned till the 10th or 12th day. I believe either method will be found a very useful one, as thereby a saving will be made to the community, and the end and design of rearing fully answered.

Mr. Young, in his fourth vol. inserts a letter, page 327. from Sir Edw. Littleton, wherein tea made of a lock of the richest hay, infused in a portion of milk proved excellent to rear calves with, and he never saw calves look so well.

In the fifth vol. page 465. of the *Memoris of the Bath Society of Agriculture*, is the following article, on the subject of weaning calves:

In the year 1787, I weaned 17 calves; in 1788, 23; and in 1789, 15. I bought, in 1787, three sacks of linseed; I put one quart of the seed to six quarts of water, which by boiling ten minutes, became a good jelly; this jelly is mixed with a small quantity of tea of the best hay steeped in boiling water.

Having my calves drop at different times, I did not make an exact calculation of the expense of this hay tea, but out of my three sacks of seed I had better than two bushels left at last. I gave them the jelly and hay-tea three times a day: to the boy who looked after them 6d. per day; the price of the linseed was 4s. 6d. per bushel; the whole three years seed 2l. 5s.

My calves are kept in a good growing state, and are much better at this time than my neighbours, that are reared by milk; and they do not fall off so much when they come to grass.

CALKINS, a name given in some parts to a sort of horses shoes, made for frosty weather.

These shoes, by forcing the horse to tread wholly on the toes of his hind feet, are apt to occasion bleyms, and ruin the back sinews. The farrier, therefore, should be ordered to pare the horn a little low at the heel, and turn down the sponge upon the corner of the anvil, so as to make the calkin resemble the point of a hare's ear, which will remove the consequences often attending the common square calkin.

CALTHA, the marsh marygold, the name of a perennial plant, growing naturally in the low meadows in many parts of England.

M. Duhamel recommends this plant to the notice of farmers, as very useful to be cultivated as a winter pasture for cattle; and experience has justified his recommendation. Perhaps it might prove as useful in this country as in France, especially as cattle are known to be extremely fond of it, and the plant might be easily cultivated.

CAMMOCK, the name of a troublesome plant infesting arable lands; but more generally known by the name of rest-harrow. See the article *REST-HARROW*.

CANARY-Seed, the name of a small seed produced by a gramineous plant, cultivated in some parts of England.

A correspondent of the *Museum Rusticum*, has given us the method practised by the farmers of the island

of Thanet, in the culture of canary-seed. He observes, that they generally chuse to sow it in fresh land; that is, such as has only borne grass. After ploughing up the lay, and bringing the land into tolerable rough tilth, they sow it with peas; these are kept clean hoed as usual, and yield a good crop. The next year the land is well ploughed, and planted with horse-beans, which thrive well in that island. These two crops effectually kill the green sward, or grass; take off the rankness of the soil; and the frequent hoeings, which are necessary to keep the weeds under, bring the land into fine tilth. After the beans are off, a thorough ploughing is given to the land, and in that condition it remains till the spring: about the beginning of March, if the weather be fine, and the season dry, the land is ploughed for the last time; immediately after which the canary-seed is sown.

The farmers in that island used formerly to sow canary-seed with a broad cast, spreading it all over the land; but when this was the practice, they found it very difficult to hoe and keep the plants clean from weeds: at present they sow it in furrows, made across the land, constantly taking care to make the ridges between the furrows as sharp as possible: by this means the seed, which is sown by hand, slips from the sides and tops of the ridges in the furrows, and the plants come up in regular rows. The plants must be kept very clear of weeds by means of the hoe, weeding-hook, &c. and if it be a wet summer, the intervals must be hoed several times; but of this the intelligent farmer is the best judge.

Three pecks of seed are, in general, enough to sow an acre, sometimes more, and often less. The canary seed seldom comes on till the wheat-harvest is entirely over, and the corn housed: but it must be observed, that the wheat harvest is generally very early in that island. It is reaped with a hook, and as fast as it is cut, the reapers lay it on the land in wads, as they call them, or parcels about the quantity of half a sheaf of wheat unbound: in this manner, if the weather be favourable, it is left near a fortnight, at the end of which time, the wads must be turned, that the other side may be dried. If the weather be very wet, they must be turned oftener, to prevent the seed from sprouting.

The price of reaping canary in that island is from six to eleven shillings per acre; and the price of threshing and dressing it is five or six shillings a quarter. According to the goodness of the land, and the tillage that has been bestowed upon it, the farmers there expect their return to be from twenty-five to fifty bushels per acre; but the common crop is from thirty to thirty-four. It must, however, be observed that the farmers never pay so much as ten or eleven shillings per acre for reaping this crop, unless the canary be very much lodged and tangled, which it often is, owing to the land in which it grows being fresh, rich, and rank, and to the high winds to which that island is subject.

They sow successive crops on the same land for eight or ten years; and sowing canary would be a very great improvement to lands which lie convenient for water carriage to London markets, was it not a crop the farmer ought by no means to depend upon, not only because the return, or quantity it yields, varies greatly, but also on account of the fluctuation in the price of this seed in the London markets, where the greatest and indeed almost the whole demand is. *Museum Rusticum, vol. I. p. 22.*

CANKER, a small speck made by a sharp humour, with gnaws the flesh almost like a caustic.

This distemper often attacks the foot of a horse, and generally proceeds from thrushes, when they prove rotten and putrid, though many other causes may produce this disorder. The method used by farriers for the cure is generally with hot oils, such as vitriol, aqua-fortis, and butter of antimony, which are very proper to keep down the rising flesh, and should be used daily till the fungus is suppressed, when once in two days will be sufficient, strewing red precipitate powder over the new grown flesh, till the sole begins to grow.

There is one great error committed often in this cure, which is, in not having sufficient regard to the hoof; for it should not only be cut off, wherever it presses upon the tender parts, but should be kept soft with linseed oil; and as often as it is dressed, bathe the hoof, all round the coronet, with chamber-lye. Purging is very proper to complete the cure. *Bartley's Farriery, p. 314.*

CANKER, in trees, implies a wound or blemish in the trunk, which does not heal naturally, but will increase and damage, if not endanger the whole tree.

The canker in fruit trees is most commonly occasioned by wet, which gets in at the cleft where the tree was grafted, or at some other wound which has been neglected: but it also proceeds sometimes from the soil's not agreeing with the nature of the tree.

If this distemper be only superficial, arising from a bruise, for example, which the bark may have received, it may be cured by cutting the injured part out with a sharp knife, and then binding over it a mixture of cow-dung and earth, tied on with a wisp of hay, likewise daubed with cow-dung. This must be done before the sap begins to rise; for otherwise the bark will peel, loosen and wither much further than the bruise, to the great hazard of the whole tree, especially if the stem be the part affected: for as to a bruised branch, the best way is to lop it off at once, if there be the least suspicion of danger. But when the canker has been bred in the tree, or when it has extended from the trunk to the branches, or from the branches to the trunk, so that after cutting away to the very quick, there still remains an eye, or speck, like that which is sometimes seen to run through a whole plant of distempered corn, the shortest way is, to commit the tree to the fire, and to plant another in its stead. Mr. Nourse is indeed inclined to think that, if the canker has not penetrated too far into the tree or stock, supposing it to be of the apple kind, it may possibly be saved, by re-grafting it with a winter quinnin, a boderan crab, a boon apple, or a golden pippin; neither of which he had observed ever to canker: but how accurate his observations may have been in that respect, we shall not pretend to determine. Certainly it may be worth while to try a change of fruit in all such cases, if they are not absolutely desperate. He asserts, upon his own experience, that the apple which we call a woodcock, is no way apt to canker, or to be blasted.

This, if it be fact, renders it by so much the more worthy of cultivation, as it is a great and constant bearer, and yields an excellent juice. The misfortune is here, as well as in the attempts which have been made to suit the soil and the fruit, that each of these is distinguished, either by such general appellations and descriptions as serve only to puzzle the husbandman when he comes to real practice, or by names which are not known out of the places where they are used. Mr. Marshall will render an essential service to mankind if he should happily succeed in that important point, which, if we are rightly informed, is the object of his present studies; viz. to ascertain by an exact analysis, which no one can be better qualified to do with the utmost precision, what are the component particles of each different species of soil, and what proportion they bear to each other. This, divested of that parade of science, and of scientific terms, which the learned are too apt to display, and which serves only to embarrass common understandings, will, should such a work appear, as it is hoped that it will soon, answer a very essential purpose in agriculture, as well as lay a fine foundation for useful entertainment to gentlemen whose leisure permits them to prosecute such studies. But the task, considered in all its various branches, is arduous indeed! worthy of that able gardener (we use the word here in its most extensive and most proper meaning) and skilful botanist, whose love for the welfare of mankind has prompted him to undertake it.

Mr. Worlidge assures us, that he himself cured a tree desperately diseased with the canker, by cutting off as many as he could of the cankered boughs, laying its roots bare during all the winter, and applying to them in the spring a great quantity of swines dung, not too new, mixed with the earth, which was then returned into its former hole. If this does not do, he condemns the tree to be grubbed up, as being past recovery. *Nourse's Discourse on the Benefits and Improvement of Husbandry, p. 138. Worlidge's Systema Agriculturae, cap. viii. sect. ii.*

CAPELLETS, in horses, are particular swellings which those animals are subject to, of a wenny nature, which grow on the heel of the hock, and on the point of the elbow; they rise from bruises and other accidents, and when this is the case, should be treated with vinegar and other repellers; but when they grow gradually on both heels or elbows, we may then suspect the blood and juices to be in fault; that some of the vessels are broke, and the juices extravasated. In this case the suppuration should be promoted, by rubbing the part with marshmallow ointment; and when matter is formed the skin should be opened with a lancet, in some dependent part towards one side, to avoid a scar: the dressings may be turpentine, honey, and tincture of myrrh. The relaxed skin may be bathed with equal

parts of spirit of wine and vinegar; to which an eighth part of oil of vitriol may be added. The contents of these tumours are various, sometimes watery, at others suety, or like thick paste; which if care be not taken to digest out properly with the bag, will frequently collect again: was it not for the disfigurement, the shortest method would be to extirpate them with a knife, which, if artfully executed, and the skin properly preserved, would leave very little deformity.

When those tumours proceed from an indisposition of the blood, they are best let alone, especially those of the watery kind, which will often wear off insensibly, without any applications: but when they are like to prove tedious, you should endeavour to disperse them by bathing the parts with repellers, and have recourse to rowels, purges, and diuretic medicines, to carry off the superfluous juices and correct the blood. *Bartlett's Farriery, p. 277.*

CAPO, a word used in Cheshire, to signify a working house.

CAPON, a cock-chicken gelded as soon as left by the hen, or at least as soon as he begins to crow.

Capons are very useful to lead chickens, ducklings, young turkeys, pheasants, and partridges, which they will do better than the hen, and at the same time make a stouter defence against kites and buzzards. The largeness of their body is also of great advantage, as they will cover between thirty and forty of them.

CARBERRY, a name given in some parts of England to the gooseberry.

CARCASE, a name generally given to the body of a horse.

The carcase of a horse ought not to be too small and slender; for a small carcased horse is generally weak. On the other hand, a very large carcased horse proves often heavy and inactive, and when he happens to be under-limbed, it is reckoned a great fault, though this remark often fails, and horses, that have been reckoned very much under-limbed, have proved as strong, and fully as serviceable as any other.

A low back is another fault that almost every body complains of, and indicates weakness, though a moderate sinking below the withers is not at all amiss, if the back be otherwise straight. When this sinking is not great, the forehead generally rises well. But when a horse has a low back, and is higher behind than before, it is not only ugly, but such horses are generally weak, are apt to be pinched in their shoulders, and have an awkward way of going, owing to the heaviness of their hind parts, which hinders them from getting on.

Some are fond of horses which are home ribbed, which is indeed a property that denotes both beauty and strength, as those that are open ribbed are looked upon to be weak and loose; but in some horses the short ribs approach so near the haunches, that they have scarce liberty to breathe, and such horses are the most out of wind of any other when put upon hard exercise, and easily get broken-winded. But a horse that is open and loose in his flanks, like a grey-hound, is liable to many disadvantages, which it would be tedious here to relate; such are always narrow over the chine, have little or no belly but what is forced by art and feeding; and though we find some of this kind more vigorous than others, and even exceed all expectation, yet the generality of such horses are seldom fit to carry a great weight, or to hold out in hard riding. Some are great admirers of short backed horses, which is a right way of judging, so far as this stands in opposition to a very long back. But some horses are so very short, notwithstanding they are otherwise of a good size, that they seem to be lost under common furniture. But when a tall horse happens to have a short carcase, and very long legs, like a spider, such horse is seldom good for much. If a horse's back be short, his whole body and limbs ought to be short, and then it denotes strength and firmness; but most of these make but a slow progress on a journey, though they will endure and hold out as long as any other, unless they are urged on with horses of greater speed.

It always denotes strength in a horse, when his carcase is of a moderate size, his ribs large, his flanks not hollow but snoot hand full, with a straight back, or but a very little sinking, his hinder parts, or uppermost haunches not rising higher than his shoulders. *Gibson on Horses, vol. I. p. 31.*

CARDOON, a kind of wild artichoke, propagated only by its seed, which is of an oval form, about as big as a grain of wheat, of a very dark green, or blackish colour, and marked with black streaks from one end to the other.

There are two seasons for sowing it: the first is from the middle to the end of April: and the other about a month later. The soil should be rich, deep, and fine. In a bed of such mould, four or five feet wide, two trenches should be opened, a foot wide, six inches deep, and at least three feet a sunder: or, to answer the same intention, the rows of holes of the same depth should be dug straight by a line stretched along the bed. These holes should be three feet asunder, and in quincunx order; or, if a trench is used, the quincunx form should be observed in sowing the seed, which is performed in the following manner. Five or six of the seeds are dropped nearly together, at the distances before mentioned, and then covered over: not with a design to let so many plants grow close together in a thick cluster; but, as the growth of these seeds is somewhat precarious, to be the more certain of having two or three plants at each stated distance: for if all of them come up, they are immediately thinned to that number; and if they miscarry entirely in any one spot, the chasm is filled up with plants taken from another place, generally a hot-bed, on which some of these seeds are most commonly sown when its heat is expiring, for a recruit in a case of need. The first sowing will generally come up in three weeks, and the latter in about fifteen days. Great care must be taken to keep those plants clear from weeds, and to water them frequently, in order to make them increase in bulk, and not run to seed. But this intention will doubtless be much better answered in every respect by a judicious application of the principles of the New Husbandry; we mean, by deep and frequent stirring of the ground on each side of the bed, letting the share or spade approach to within a very few inches of the plants.

Towards the latter end of October, the cardoons thus cultivated will be fit for tying up, in order to be blanched. In order to this, a dry day should be chosen, when all the leaves of each cluster being collected close together, wisps of straw, or long litter, should be twisted round them so as to prevent the access of the air to any part of them, except their very top, which should be left open. In a fortnight or three weeks the plants thus covered will become white and fit to eat.

This tying up, and blanching of cardoons, may be continued till the winter approaches, and then those who are fond of them as to think it worth their while to be at the trouble, may take them up, with some earth about their roots, and remove them into a green-house, if they have one, or into a cellar, and by that means keep them for use all the winter. Some of these may be replanted in the spring, in an open border, as before, to seed in June or July; or they may be cut down to the ground, when thus planted anew, and their second year's shoots may be tied up and whitened as before.

Besides the use which the Italians, French, and Spaniards, make of this cardoon, in eating it raw with pepper, salt, oil, and vinegar, many think it preferable to celery, when stewed, because it is mellow, and much more tender.

CARLICK, the same with charlock. *See the article CHARLOCK.*

CARPET-WAY, a green-way, or path left in an arable field, without being ploughed.

CANE, a hollow place where water stands. It also implies a wood of alder, or other aquatic trees in a moist boggy place.

CARRIAGE, a general name for carts, waggons, and other vehicles, employed in carrying timber, corn, persons, &c. from one place to another.

CARRIAGE, also signifies a furrow, or trench, for conveying of water to overflow and improve meadow-land. It is distinguished into two sorts; the main carriage, which should be made with a convenient descent; and the lesser carriage, which should be shallow, and as many in number as possible.

CARROT, the name of a root too well known to need any description here.

The Society for the Encouragement of Arts, &c. being persuaded that the cultivation of carrots for the food of cattle could not fail of being advantageous to the farmer, published a premium of twenty pounds to the person who should sow the greatest number of acres with carrots, for the feeding of cattle only; adding, that it was expected the person who received the premium should give an account of the soil, culture, time of taking up, and their effects on the cattle fed with them.

This premium was accordingly given in the year 1766 to

to Mr. Robert Billing, a very intelligent farmer at Weasenham in Norfolk, he having sowed thirty acres and two roods of land with carrots, for feeding cattle only. At the same time he sent an account of the methods he used in the culture of his carrots, which was so well approved of by the society, that it was published at their request: an abstract therefore of this pamphlet must, we presume, be very acceptable to the reader.

Mr. Billing observes, that the use of carrots for the winter-feed of cattle has been long known and practised in the eastern parts of Suffolk, where it is common to make carrots serve the same purpose turnips have many years done in most parts of the county of Norfolk; besides, that many are sent from thence to the London market: but carrots never have been sown in the latter county, for the maintenance of cattle, till he tried a small parcel in the year 1761, and another in the year 1762.

He thought it prudent, he says, to make these trials before he came a candidate for the premium offered by the Society; the hopes of deserving which encouraged him to venture a pretty large and unusual expence, as well as the loss of a great part of his winter crop, and which has thus become the means of making known, in his part of the country, a species of husbandry with which they had before no acquaintance but by hearsay, being above fifty miles from the country where it had before prevailed.

In the year 1763, he sowed thirty acres and a half by mensuration.

This quantity of land lying in three parcels, one, of thirteen acres, bore wheat in the year 1762; one, of half an acre only, had borne clover; and the last, of seventeen acres, turnips that year. The piece of thirteen acres is a cold loamy soil, shallow, and upon a sort of loamy gravel. The half acre is a soil much mixed, upon a moist clay, the seventeen acres may be divided into two parts, the one of fourteen acres, and the other of three. Both are a light and dry soil, newly improved with a marle; the former, an exceeding good tempered soil, upon a marle; the other, a shallow black sand, upon a kind of imperfect grit-stone, called, in Norfolk, a carr-stone.

Previous to giving an account of the success of his crop of carrots, and of the use he made of them in feeding cattle, he describes the manner in which he cultivated these several pieces of land, founded as well on the best information he was able to procure, as upon the observation afforded him by his own experience of the former year.

The wheat and clover stubble he split down with the plough early in the preceding November, and is satisfied, from all the observations he has made since he first begun the cultivation, that whether the wheat stubble be, as it is called in Norfolk, flat work, or in ridges, or the carrots are to be sown after clover or rye-grass, the land cannot be ploughed too early; so that the frost and snow may have their full effect in mellowing the ground for the reception of so small a seed; and this is the more necessary to be attended to, the stiffer and tougher the soil shall chance to be.

The land that had been turnips he let alone till the end of January, or beginning of February, thinking this time enough, because the earth was thoroughly cleaned by the cultivation and summer hoeing necessary for the crop of turnips.

Of the thirteen acres of wheat stubble, six were dunged for wheat, but not for carrots; four and a half not dunged at all; and two and a half for the carrot crop only. The clover land was dunged for the carrots: and of the seventeen acres that had been turnips in 1762, part had been tatted for the turnips, that is, where sheep had been folded; and the whole crop of turnips was fed off by sheep and neat cattle.

Four pounds of seed on an acre is sufficient: but as the seed is very small, light, and hard to separate and disperse equally on the ground, he was at first a good deal puzzled how to overcome this difficulty; and though he was advised to make use of a mixture of sand, he did not find it answer, because the weight of the sand carried it all to the bottom of the seed cot: he sows it therefore now unmixed, as they do turnips, after having forced it through a fine chaff-sieve by rubbing.

It will be three weeks, after sowing, and sometimes longer, before the carrots appear: this is the principal advantage, besides the difference of expence, the turnips have over them, for the latter are not sown till about Midsummer, and coming quicker to the hoe, get the better of the weeds

more easily; for weeds do not grow near so fast about Midsummer, as in the spring.

The carrots lying a longer time before they come up, and continuing afterwards a long time very weak, they are seven or eight weeks before they are fit for the hoe, and in the mean time afford the weeds an opportunity to get strength, in a season too, when unluckily they grow the fastest: Mr. Billing is therefore of opinion, that though it is necessary to sow carrots before turnips, it is better to sow them as late as you can with safety to the crop; for of his, those sown in April on the clover stubble came much the soonest to the hoe, though later sown.

The wheat and clover stubble were ploughed three times; the piece after turnips but twice; the first time shallow, the second as deep as the staple of the ground would permit; and on this ploughing the carrots were sown.

As it would remove some of the objections to a carrot crop, and lighten much the expence of weeding, could they be sown later, and as this might be done could the seed be made to come up sooner, this sensible farmer imagines the seed might be steeped in somewhat that would forward its vegetation, and afterwards sown, when dry enough to separate.

Yet however expensive the strength of the weeds in a crop of carrots makes the hoeing of them, the crop itself is not apt to suffer, for though the young carrots are quite covered in a thicket of weeds before hoeing, and should be buried in earth after the hoeing; yet they seem no way hurt if they get clear again, as they generally do in a fortnight after, if not cut off, or buried too deep, for want of skill in the labourer.

The Norfolk hoe is six inches wide. If the carrots chance to be tolerably clean, they may be hoed the first time for eight shillings per acre; but if the ground be full of weeds, occasioned either by much rain, the foulness of the ground before sowing, or the length of the time between the sowing and hoeing, the first hoeing will amount to ten or twelve shillings per acre.

About ten days or a fortnight after hoeing, they should be harrowed: this will displace the weeds, and prevent their growing again, which many of them will otherwise probably do, especially if it be showery weather: the harrowing does not hurt the carrot plants, but, on the contrary, does them much service, by bringing fresh earth to them, as well as killing the weeds.

About three weeks after harrowing, in case it has not perfectly cleared the ground of weeds, or in case new weeds come up, Mr. Billing hoes the carrots a second time, which costs about four or five shillings per acre, as the ground is more or less foul: and after this, if there still remain any weeds, which will be the case if much rain falls during the time of the second hoeing, a second harrowing is bestowed.

Where the weather has been favourable, and those employed in hoeing have done their duty, the carrots once hoed and harrowed have been as clean as those on which two hoeings, and as many harrowings have been bestowed.

Mr. Billing next proceeds to inform us of the success he had in the year 1763, on the several parcels of ground already described. His carrots proved best on the piece of two acres and a half that had been wheat, not dunged for the crop of wheat, but dunged for the crop of carrots, and on the half acre clover stubble dunged for the carrots.

Many of the carrots out of both pieces measured two feet in length, those on the former from twelve to fourteen inches in circumference at the upper end, and those of the latter from twelve to sixteen; a difference of bulk owing, perhaps, both to the different soils, and the effect of former crops.

On the two acres and a half Mr. Billing computes he had from twenty-two to twenty-four loads per acre, and about fifty-five, or fifty-six cart-loads on the whole: the half acre on clover stubble produced about twelve loads; the six acres and a half dunged for wheat, but not for carrots, produced from eighteen to twenty cart-loads per acre, and in the whole about one hundred and four loads; the four acres not dunged for either wheat or carrots, produced from twelve or fourteen loads per acre, and in the whole fifty-two loads.

He had but an indifferent crop of turnips the succeeding year, on the seventeen acre piece, but had from sixteen to eighteen cart-loads per acre of carrots on fourteen acres of it, but a very poor crop on the three remaining acres; so that

that he computes he might have on the seventeen acres after turnips not quite two hundred and seventy loads, which make, with the former, about five hundred and ten loads of carrots, equal in use and effect to near one thousand loads of turnips, or three hundred loads of hay, as experience has convinced him from the various methods in which he had tried them.

Mr. Billing thinks it is not improbable that he might besides lose five or six loads, which the poor people took, instead of a single load they might have stole, had the land been cropped with turnips; but this loss will be evidently much lightened, should the growth of carrots become general in the country.

The best method of drawing the carrots is with a four tined fork, with which a man breaks the ground six or eight inches deep, very carefully without injuring the carrots; and is followed by a little boy, who gathers the carrots, and throws them in heaps.

Our farmer began to draw his carrots for use about three weeks after Michaelmas; but as the cattle he intended to feed on them had never been used to so hard food, he thought it best to give them, at the same time, both cabbages and carrots, lest they should suffer by a distaste at the beginning.

He had about forty load of cabbages growing on one half acre, equal in use, as appeared on trial, to about seventeen or eighteen loads of carrots. He observed, that cattle of every sort naturally eat the cabbages as readily as they would have done turnips; and soon after having gradually learnt to eat carrots, began to prefer them. Both the cabbages and carrots, and afterwards the latter with turnips, were brought from a place where they grew, to a pasture close; and, without any other preparation than shaking off the dirt, they were dispersed on the ground for the cattle to feed on promiscuously.

From the experience Mr. Billing has had in fattening cattle on turnips in houses or stalls, he is persuaded that by this means the carrots might have been made to go a great deal further; but besides the great trouble attending this method, especially if the number of beasts be great, and the hazard of beasts foundering in the way to London, an accident that often happens to stall-fed cattle, and that the benefit of their stale is lost to the ground, he is convinced the beef is not so good, though perhaps more slightly.

The first flock he began to feed in this manner consisted of twelve neat beasts, and forty-nine shearing weathers, or those not quite two years old: ten of the former were Norfolk bred steers, and began to feed on the first carrots he drew: at the same time he put on a cow, and a heifer three years old. At old Martinmas, Mr. Billing bought seventeen Scotch bullocks, which, with a cow from his dairy, made up the number thirty; and soon after he increased this number to thirty-three, by adding three more from his dairy.

It is, however, to be observed, that when the cabbages were spent, he allowed a load of turnips each day for some time for this flock of cattle, which, with three loads of carrots, was a sufficient provision for them. This enabled him to determine, that one load of carrots is nearly equal to two of turnips; for if the cattle had been fed on turnips only, it would have cost him little less than seven loads, computing on the experience of many years fattening cattle with turnips; yet he declares he never knew cattle thrive faster.

Nine of the steers were sold fat in Smithfield on the seventeenth of February, and weighed about forty Norfolk stone, that is, seventy London stone, each. Another steer and cow were killed in the country, the latter at Weasantham town, and which died very fat, about the same time: the Scotch were sold at St. Ives about the beginning of May: the steers sold in Smithfield for about seven pounds fifteen shillings each.

Our farmer being told the market was then low there, sold all the Scotch, except one, at St. Ives, where they fetched him about seven guineas each.

The former cost about four pounds ten shillings each; the latter three pounds fifteen. The other Scotch he sent to London, where, though it weighed but a little above sixty stone, it sold for eight pounds, and was said to be some of the fattest beef killed in London that winter, as Mr. Billing was informed by Mr. Brownworth the salesman: the others were not inferior.

The forty-eight weathers were sold at St. Ives in the month of May, at about fifteen shillings each.

These thirty-three beasts, and forty-eight sheep, brought Mr. Billing, according to his computation, about one hundred and twenty pounds profit; out of which deducting one tenth for the share the cabbages and turnips had in fattening them, which is rather too much, especially as the cattle soon began to leave the turnips, there remains one hundred and eight pounds to be carried to the account of the carrots.

The large quantity of carrots our industrious farmer had growing gave him also an opportunity of trying their use in feeding dairy cows, sheep, horses, and hogs.

In the month of April he found he should have nine or ten acres to spare, beyond what is necessary to complete the fattening his bullocks. This happened too at a time when his turnips, as well as those of his neighbours, began to decay, and enabled him to supply that defect, to which the Norfolk farmers are very subject in the spring of the year, and which no method of managing their turnips ever exempted them from, when the weather is wet and frosty by turns; and from this decay the carrots seem protected by their hardness. From this time he fed his whole dairy of thirty-five cows, and his flock of twenty-one score of sheep, on carrots.

At the same time he thought of a method of getting the carrots out of the ground with more ease and expedition than he had done before, which was of great use when he had other occasions for his servants; besides which it also prepared the land better for the ensuing crop.

They were ploughed up with a narrow-sharred wheel plough; going slow, the share opened the earth, and cut very few of the carrots; those few being only such as chanced to meet the very point of the share.

The plat or earth-board, turned most of the carrots out of the ground, and, by harrowing afterwards, were most of them quite cleared from the earth. Though the roots extended a good way in the ground, and below the pan, he did not think it necessary to plough so deep, and consequently the land suffered no damage which otherwise it might have done, as some few of the carrots instead of being turned out, were buried: it is also necessary to plough the land and harrow it a second time; but though this should be at an interval of a month, the buried roots will take no harm.

Mr. Billing turned his dairy cows and flock of sheep on this land after the ploughing, without any further trouble or preparation, and had all the reason in the world to be pleased with the event; both took readily to eating the carrots, though he thinks the cows more so than the sheep.

The former not only gave more milk than is usual at that time of the year, but many continued to give milk, which would with such turnips as he had then to give them, have been nearly dry. The butter made was likewise much better than that of turnips; and both sheep and lambs did much better than he ever remembers them to have done at this season of the year: besides this, the land was evidently very much improved from the stale of the cattle, of which he plainly perceived the benefit in the ensuing crop.

It is proper to observe, that in this method, some few of the carrots continued buried, even after a second ploughing; but these were turned out upon a third ploughing, when barley was sown, and were clean eaten up by a flock of sheep, without any injury to the new sown barley.

In this manner the cows and sheep were fed for three weeks, which Mr. Billing values at about twenty pounds; and, considering how he might have suffered, had he wanted turnips, and not been able to supply that want with carrots, he thinks, he might value his feed at a great deal more.

In November 1763, he began to feed sixteen horses, which did all his farming work, with carrots: they had neither hay nor corn, except his team that carried his corn to Brancaster, a sea-port, at fifteen miles distance: to this team he allowed a bushel of oats a day: the rest had nothing besides carrots, except pease-straw and chaff, until the sowing barley. In April he increased their work so much, that he thought it necessary to give them a few oats; but they continued to subsist chiefly on carrots, until they were turned to grass, the latter end of May.

Mr. Billing declares he never knew his horses in better order or do their work better; and they were so fond of carrots, that he frequently found, that when the team mentioned before was so fatigued, that they refused to eat their

their corn, they would eat it when mixed with the carrots chopped.

It may be proper to observe, that he always chopped off the heads and tails of the carrots he gave his horses, and sometimes gave them another cut. Though he could not find it was necessary, he mashed them also for his horses, none of which trouble he found at all requisite, or even useful for other beasts: the gathering and removing the carrots, and dispersing them about the pasture-land where he feeds cattle, were sufficient.

Mr. Billing gave the sixteen horses two loads of carrots every week; and these two loads, he computes, saved him more than a load of hay; which, at twenty-five shillings a load, amounted to thirty-five pounds.

To this might be added, the benefit received by the swine, to which he threw all the tops and tails of the carrots used for the horses; and they thrive exceedingly, and were so fond of them that he never could find that any dirt which might stick to them, prevented their eating them: but as the principal part of the food of the swine was milk at first, and afterwards pease, our farmer has not set any value on this part of his profit: the total of what he has estimated is on the other articles, amounting to one hundred and sixty-three pounds.

Of the thirty acres and a half, four were sown in the year 1764, with oats, all the rest with barley: the four acres were part of the land where he ploughed up the carrots; the rest of this piece was sown with barley; both produced a prodigious crop, not less than three loads of corn in the straw, per acre: on the rest of the land his crop was less bulky, and shorter, yet very good, perhaps not less in the quantity of grain than the other. And here it may not be improper to mention, that when in a former year, he had sown the two ends of a large close with carrots, without dung, and the middle with turnips, for which the land was well dunged, yet, when the whole enclosure was, the next year, sown with barley, that after the carrots was the best.

Another recommendation of carrots is, that our intelligent farmer finds them a more certain crop, both for growth and duration, than turnips: the latter are exceedingly apt to fail, as well as rot, towards the spring, when most wanted. Perhaps the former is, in some measure, owing to the lands in Norfolk being, as the farmers express it, surfeited with turnips, to which they have been so long accustomed. But however this be, there are many reasons for chusing both, that if one fail, we may rely, for so necessary a winter provision, on the other.

This candid farmer thinks he ought not, however, to conceal, that at the first beginning of a new sort of husbandry, many difficulties stand in the way: the expence is very heavy, much beyond the expence of turnips, and is, perhaps, increased by the awkwardness of labouring men and servants, who are both ignorant and perverse about most new employments: besides this, the cleaning of carrots from weeds is much more necessary than of turnips, and yet goes on much slower, so as sometimes hardly to be completed: and, moreover, if a long continued frost should happen, it will be very difficult to get carrots out of the ground (indeed the turnips in this case are apt to spoil;) but this inconvenience may, in some measure, be prevented, by drawing the carrots before the frost; though this will be attended with difficulty when the quantity amounts to fifty or a hundred loads.

Such is the account given by Mr. Billing, with regard to the culture and use of carrots, for the feeding of cattle. And as these experiments were made so much at large, the farmer may, without hesitation, adopt this method; and if his soil is adapted to the growth of carrots, he need not doubt of greatly increasing his annual profit. That they are wholesome feed for cattle has been long known: but that such advantages resulted from their use as Mr. Billing relates, few farmers could have imagined.

The advantage resulting from carrots is pretty fully set forth in this experiment, but would have been still more obvious had Mr. Billing ascertained the weight of his loads of carrots, and other vegetables made use of.

Carrots are also very useful for feeding hogs, as appears from Mr. Young's experiments on that subject, one of which may be proper to insert here.

"In January 1766, says he, I drew from the herd ten hogs, as equal in size as possible, and weighed them alive in five lots.

	stone.	buishels.	stone.	lb 6
N ^o 1. weighed	13	4 eat of pease	16	weighed 27
2.	12	6 pollard	80	27 9
3.	13	0 buckwheat	27	29 13
4.	12	11 potatoes	28	25 7
5.	13	1 carrots	49	31 0

- N^o 1. was fatted with white-pease, that weighed 66 pounds per bushel, the price 1l. 10s. a quarter.
 2. with pollard, weighed 22 pounds per bushel, the price nine-pence per bushel.
 3. with buck-wheat, weighed 47 pounds per bushel, price 2s. 3d. per bushel.
 4. with boiled potatoes, weighed 54 pounds per bushel, price 2s. per bushel.
 5. with boiled carrots, weighed 55 pounds per bushel, raw, price 1s. 1d. per bushel.

"I thought it best to fix on a given sum, as proper to fat each hog. The people I consulted with were of opinion, that eight bushels of white pease were necessary to fat one such hog well. This I accordingly fixed on as my criterion. The account of the expence therefore stands thus:

	l.	s.	d.
N ^o 1. Pease 16 bushels value:	3	0	0
2. Pollard 80 bushels.	3	0	0
3. Buck-wheat 27 bushels	3	0	9
4. Potatoes 28 bushels, 2l. 16.	3	0	0
Labour and coals 4s.			
5. Carrots 49 bushels, 2l. 13s. 2d.	3	0	0
Labour and coals, 6s. 10d.			

Each lot was weighed as soon as the food was done. The result was as appears above in the third column.

"It is evident, says Mr. Young, from this experiment, that carrots boiled are superior to any other food. I did not expect that potatoes would be so much inferior: but I have found from divers other trials since, that it is requisite to mix the meal of some kind of corn with them. Pollard in this trial, as in the last, is superior to pease."

The superiority of carrots over potatoes in this experiment, does not consist in their being more feeding than potatoes: for 28 bushels of potatoes advanced the weight of the hogs, lot No. 4, 12 stone and five pounds; whereas 49 pounds of potatoes, the weight of the carrots made use of by lot No. 5, would have advanced them 21 stone 5 pounds, and the carrots advanced them but 18 stone. The reason of the carrots appearing superior in the experiments, is on account of the price, the carrots being rated at only half the value of the potatoes per bushel; a disparity that seems too great to hold generally: for potatoes may be cultivated more extensively than carrots can be, as they require a more particular soil than potatoes; and the expence of cultivating them is greater than that of potatoes, particularly in the articles of hoeing, and taking up according to Mr. Billing's experiment.

It appears likewise from other experiments, that as weighty a crop of potatoes, or nearly so, may be raised upon an acre of land, as of carrots; and in that light the potatoes will go farthest in feeding hogs, which, will be a principal consideration with farmers, who have the option of raising either of these crops. Upon the whole, both these roots are highly valuable to farmers for the purpose of feeding hogs, as they are for feeding various kinds of cattle; in which respect, indeed carrots appear to be the most universal.

Wild CARROT, Bird's-nest, or Bee's-nest, the name of a biennial weed common in pasture grounds. It greatly resembles the cultivated carrot, of which indeed it is only a species. The wild sort however differs from the cultivated in its roots, which are small and sticky. In both sorts, after they have done flowering, the umbels contract themselves into the shape of a bird's nest.

Carrots are very hearty and nourishing food for all sorts of cattle, and very proper to feed or fatten them. They cannot, however, be brought into so general use, as some other roots, such as potatoes, turnips, or as cabbages; unless they could be cultivated in strong land, which hitherto has been supposed improper for them; because their lateral roots are so very slender and weak, that they cannot spread or penetrate into strong land. The sandy soils are some of them rich, and such are found to be very proper for

carrots. Yet strong land is generally richer than sands, and not only consists of more minute parts than sandy land, but is capable of a higher degree of fertilization, with the assistance of good tillage and manure. The only difficulty here is, by what means strong lands can be kept open, and in fine tilth, while the carrots are growing in it; for in regard to the preparation of the land, before the carrot seed is sown upon it, that it may be done by deep ploughing, and bringing the land into fine tilth for the reception of the seed. Gardeners do, indeed, raise carrots upon different sorts of land, strong as well as light; but they do not desire their carrots to grow large, and for that reason they sow the seed thick, and allow their carrots to stand close upon the ground, not usually more than eight or ten inches distant from each other. They likewise cultivate their ground well, and deep; manure it highly, and give it several hand hoeings, which destroys the weeds, and loosen and improve the surface of the land. These operations are expensive, but are notwithstanding necessary; and as we shall shew, will, with some variation, be very profitable to farmers, even in large concerns. A valuable instance of this we have in Mr. Baker's report to the Dublin Society, for the year 1771.

In 1769, and 1770, he laid a large quantity of manure upon the head lands of one of his fields, ploughed them well and mixed the manure with the land, and then carried off all the staple thus mixed, and spread it on a field for a dressing, the under stratum of this ground was a strong poor earth, upon which he had a mind to sow carrot seeds for an experiment.

"I intended, says he, to sow the carrot seed in March, but the extreme drought and husky winds, which we had all the spring of this year 1771, prevented my getting the ground into that fine order, which I conceive to be necessary for the reception of carrot seed. At best, no one will conceive this ground to be well adapted to carrots, after having taken away the natural staple. But I was inclined to try them upon my land, with an hope that if I succeeded here, I might have expectations upon some other field of the farm; and accordingly have determined upon a field of four acres for this purpose, which I shall prepare as fast as I can.

"As I could not sow the seed, for the experiment now before us, when I intended, I rubbed a pound of it in about half a bushel of fine riddled mould, and kept it there three weeks, with an hope that the seed would be somewhat forwarded, thereby to make it vegetate the sooner, and to break its natural cohesion, which renders it very difficult to sow: accordingly when I came to sow it, I found it a good deal swelled, and the adhesion very much abated."

[The hairs on the borders of this seed occasion it to adhere so closely, that it is impracticable to sow it even till these hairs are rubbed off; which if not done before the seed is mixed with mould, by which it is swelled and softened, it cannot be well rubbed afterwards to get off the hairs without damaging the seed; for which reason, the best way is to get off the hairs at first, by rubbing the seed once or twice through a fine wire sieve. A seedsmen, who can sow turnip-seed well can sow carrot-seed even and alone, when thus prepared, much easier than can be done when mixed with earth, sand &c. because such mixtures being of a different specific gravity from the carrot-seed, they fall upon the ground unequally; by which the seed is unavoidably sown in patches too thick, in some parts, and in other too thin as happened in this case; though the quantity of seed one pound to eighteen perches, (the quantity of land of this experiment) was more than sufficient to have sown it all very thick.]

"On the 20th of April we had gentle rain; the 21st and 22d light showers: I caused the ground to be three times ploughed and harrowed without intermission. On the 22d of April I had the seed sown, and bush-harrowed the ground: after the second ploughing I drew out twenty-one horse-cart-loads of dung, spread it over the ground, and ploughed it in.

"I frequently looked to see if there was any appearance of the carrots, but to no purpose for a long time: at length I imagined they were coming up very thick; but behold what I took for carrots proved to be what the labourers call dog-fennel; a weed which excoriates and inflames their skins in harvest where it touches. It appears to be a sort of fingle, or wild chamomile; however, at last some carrots were distinguishable enough; but the long continuance of dry weather prevented their going on with any vigour; and therefore, not distinguishable enough to venture the hoe among them; and that more particularly, as I have not an experienced and expert hoer.

"However, on the 28th of June I began to hoe them; for the weeds were so immensely thick that the few carrots which were distinguishable, were almost lost.

"The hoe we began with was a very light four inch hoe: in a moment I saw from the dryness and hardness of the ground, and multiplicity of the weeds, many with strong roots, that this instrument would never do; and the clods were so hard as to kick them about in spite of the man's greatest care, and by which mischief was unavoidable. I instantly ordered an hoe to be made with a bevel edge under, and flat above; a little like an adze, two pounds and a half weight, well steeled and tempered like an axe, with an hammer over the eye to break the clods. It was pleasing to see with what facility he cut up the weeds with safety to the carrots; the weight and sharpness of the instrument, added to its particular set and bevel edge, gave it a power which no arm could have given to the other.

"The continuation of dry weather soon parched up the weeds, and the carrots looked very pert in a few days; but vastly too thick on one side of the ground, and abundantly too thin on the other, wholly from unequal sowing.

"The rain we had on the 9th of July, and again some days after towards the 19th gave new vigour to the carrots; and where they were not very thick, they were of a fine black green, but a new creation of weeds also appeared. On the 23d of July the carrots were hoed again, thinned, and set out as near as could be a foot asunder: some of them were pulled up, most of them 9 and 10 inches long, quite strait, but a little indented in their sides, and about as thick as my thumb: their being indented I attribute to the extreme hardness of the ground from the dry weather. The 25th, 26th, and 27th, rain stopped the hoeing: on the 29th the hoer proceeded again; the rain stopped him again, and he did not finish this second hoeing until the second of August: he was four days at it, which came to three shillings and four pence.

"August 20th he began to hoe them again the third and last time; when I had the mortification to see great damage had been done by stealing them: this hoeing took the man two days and a half at 10d. per day, amounts to 2s. 1d. They grew away at a great rate indeed; and although my crop, from having chosen improper ground, unequal sowing, and plunder, was not large; yet I shall be encouraged by the attempt to proceed farther upon this farm in their culture.

"On the 8th of November I had the crop dug with three pronged forks, the common forks I found too weak for this use: when the carrots were brought home, I had them topped and pointed, and all the particles of dirt rubbed off, and then weighed; they weighed one ton thirteen hundred and a half; the tops and points weighed ten hundred and a half.

"It was a great pleasure to me in the sequel of this experiment, to find that I had many carrots after being trimmed, that weighed two pounds and three quarters: I weighed several, and I am confident there were hundreds of the same size. This fact is a great encouragement, since carrots of two pounds each, at a foot asunder, will afford 63 tons an acres; a produce that it is reasonable to imagine will bear almost any expence in culture.

"I shall now state our whole expence, in order to ascertain what these carrots cost per hundred weight.

DR. CARROTS, CULTURE, &c.

		per experiment.			per acre.		
		l.	s.	d.	l.	s.	d.
April 22.	To ploughing three times as deep as possible, - - -	0	1	2½	1	6	0
	To sowing and bush-harrowing three times, - - -	0	1	0	0	5	0
	To drawing out 20 loads of dung, (say 320 loads per acre)	0	1	10	1	6	8

		£ 1	11	6½	£ 15	17	17

By 10½ C. of tops and points, at half the value of straw, i. e. 4½d. per C. which I believe they were worth for the cattle and swine, - - - - - 0 0 11½
£ 1 7 7

" Thus we see that these carrots cost me 11. 6s. 6½d. which, according to our produce of 33½ C. is per C. 9½d. If in the judgment of the reader the tops and points should not be valued at any thing, which I own in my estimation would not be just in such an enquiry as this, in that case, the carrots cost 11 ¼d. per hundred weight.

" Mr. Young in his general estimates of the value of carrots, values them from 12 to 14 pence per bushel; and I collect from his writings that a bushel is about half an hundred. Now, if this valuation shall hold good in the general application of them for horses, horned cattle, and swine, even at the price they cost me per hundred in this my first attempt upon this farm, they surely must be a crop of very noble profit: however, as I believe we are not yet arrived to that excess of price for meat which I hear prevails in England, since I left that kingdom; in our culture of carrots we cannot expect to make so much of them as Mr. Young's experience has afforded in England: but suppose with us they should be found worth twenty shillings a ton, the experiment now laid before the reader, even in that case, shews a profit which is very inviting.

" The produce in this experiment I consider not half a crop, owing to late sowing, long drought, improper ground, imperfect hoeing, irregular sowing, (for one side of the ground had only here and there one) and the hand of violence; and yet the produce cost, including all charges, only 16s. 3d. a ton. This fact I have pleasure in laying before the public, because it is an important one.

" As to the application of the present crop, my quantity was insufficient to do any thing with accuracy: I shall only observe, that they have been consumed by the swine in the house; where they are greatly preferred to any garden carrots, on account of their extraordinary sweetness.

" We see, that including every article of the charge, that in the commencement of the carrot husbandry upon a farm, an Irish acre of carrots, according to the charges incurred upon the experiment before us, will cost about sixteen pounds, (nearly ten pounds per English acre) I own a formidable sum; but if the crop shall be worth from twenty to sixty pounds, the expence is surely well laid out.

	Ton.	C.	qr.
Our acreable produce of clean trimmed carrots was - - - - -	15	5	2
Of tops and points - - - - -	4	14	2

It appears from this experiment, that carrots will thrive well in strong land, if properly prepared for them; a circumstance of great importance to farmers, as they may obtain good crops of this valuable root on most sorts of land, whether strong or light, provided the land is dry, or free from springs.

The culture of these carrots was very expensive, particularly the hand-hoeing, which cost 3l. 16s. 10d. though only about half the land was planted; and is at the rate of near 2s. 8d. per acre for hand hoeing; whereas had these carrots been drilled in rows a foot asunder, the hoe-

ing would not have cost above one third of that sum - and less than half the seed sown here would be sufficient to drill.

But as a good depth of mould is a material consideration in the culture of carrots, it is much better to drill the seed upon the ridges than upon level ground: I have found upon trial that excellent carrots may be raised upon a strong loam, ploughed into three feet ridges, one row upon each ridge horse-hoed; but ridges about four feet broad are better; for they may be trench-hoed, or to the depth of two furrows; by which it was obvious the carrots will grow to a great size, much larger than they can be advanced to by hand-hoeing, and upon level ground, and, which are material considerations, at a less expence, and the land more improved than by any other method of culture. Many of Mr. Baker's carrots were two pounds and three quarters each; and if upon four feet ridges, and six inches distant in the rows, this is two carrots upon every four square feet of ground, which weighing three pounds each, is above twenty-nine tons per English acre.

That this estimate is a very moderate one, may appear from what Mr. Young relates, " that from light sandy loam, or rather absolute sand, so loose that a shovel with very little force would penetrate into it a yard deep, carrots were raised upon this soil, which when taken up in October, some of them were as large as the body of a quart bottle; very long and straight; and they had often upon this land from twenty to twenty-four loads on an acre, each forty bushels." See the Farmer's Letters, p. 216. A bushel of carrots weighs about half a hundred weight, or 56 pounds; so that these crops were from 20 to 24 tons of carrots upon an acre, a very valuable crop obtained by hand-hoeing. It is a circumstance of great encouragement to farmers to cultivate carrots, considering that they may obtain as large crops of them upon poor strong land, as from such rich sand as Mr. Young mentions here; and that even greater crops may be had from ordinary land, and at a less expence by the horse-hoeing culture.

The whole expence of this culture, viz. horse and hand-hoeing, will not amount to half the cost of hand-hoeing in Mr. Baker's method; with this further advantage, that by deep ploughing the earth from one side of the rows, the carrots may be drawn up easily with a fork, or even by hand, at a very small expence; and one pound of seed is more than sufficient to drill an acre; for by some trials I found that a pound of carrot seed rough, (or before the hairs were rubbed off) evenly sown broad-cast will furnish full sixty seeds to every square yard of land. If therefore this seed is drilled upon four feet ridges, a single row upon each ridge, every two feet and three inches length of the ridge contains a yard square of ground, upon which 60 seeds being drilled, they will not lie quite half an inch in the row; and every six inches length of row will have 13 seeds in it, and only one carrot is necessary in 6 inches to produce the above crop.

Carrots are of singular use to farmers, being very nourishing food for all sorts of cattle, which are all fond of them. In Mr. Billing's experiment upon carrots, he takes notice

notice that in feeding his cattle with them, he found that two loads of carrots went nearly as far in feeding them as three loads of turneps; and they are not only a surer crop, and liable to fewer accidents, but also more proper to be stored for feeding cattle in winter and spring than turneps; but the turnips do not occupy the land so long.

Mr. Marshall recommends 6 or 8 lb of carrot-feed to be scattered on an acre, in flutes, a foot apart, and two or three inches deep; covering the seed in such a manner as to leave obvious traces of the rows. This will give an opportunity of keeping down the interval weeds with the double hand-hoe, before the carrots come up. As soon as the plants are distinguishable, hand-weed the rows, and continue to hoe the intervals.

CAR-SICK, a term used in some of the northern counties to signify the cart-rut, or gutter, made by the wheel of a cart or waggon.

CART, a vehicle mounted upon two wheels, and drawn one or more horses.

The chief difficulty in the construction of wheel-carriages, consists in properly adapting the wheels and axle, which ought to be done in such a manner, that the carriage may move with the least force possible. *See the article WAGGON.*

The carts of Norfolk, Mr. Marshall says, have a singularity pertaining to them. The shafts instead of being fixed hinge-wise to the axle, or to the bottom of the cart, are a continuation of the side-pieces of the bottom itself: of course, the Norfolk carts do not tilt in the manner in which carts in general do. In setting on manure, a long-belly-band is made use of; so that the shafts rise with the fore part of the cart; the shaft-horse being the only stay to its tilting up entirely, nor is this an uncommon circumstance; the shaft-horse, in this case remaining upon his hind-legs, until he be drawn down again by the fore-horses. This, to common observation, is an awkward and a barbarous custom: yet it is not often that the shaft-horse receives any injury from this practice. A broad soft belly-band, of leather or hempen, ought however to be used on this occasion. The iron chains, which are frequently used are painful to the eye at least.

Marling, it is probable, brought it into use: as the wear and tear of carts in this rugged operation is endless; the simplest, strongest, and least expensive cart, has of course been for ages, most used; and it is probable that a more simple, a stronger, or a less expensive cart, cannot be devised, than that above described. Carts of a common structure, of which there are few now used, here, for particular purposes, are called tumbrels.

CARTER. *See SERVANTS.*

CART-HORSES, agreeable to Mr. Marshall in his Minutes of Agriculture, are not equal to oxen, either in their support, labour, or profit. Indeed, he says that cast-off coach-horses or saddle-horses, if strong, though slightly tamed, do very well. If the work be light, they step quicker; and if not too gay, are preferable to heavy cart-horses for whip-reins. Horses are subject to fret and bathe themselves with sweat, while oxen seem unconcerned with the same labour, and chew their cud. The expence of their keep is considerably above that of oxen; viz. a team of horses for four months cost in keep between 25 and 30 pounds, while a team of oxen for the same space of time only cost about eight pounds. He has made a general remark, that whatever horses do, oxen can do temporally; but whether they can work every day in the year, he could not determine. But he says that horses kept only on hay with oxen, cannot support the fatigue of work so long as the oxen. He recommends discoloured barley in preference to oats, and three-fourths of the same quantity will be sufficient to have the horses improve upon it, and as the discoloured barley will fetch but the same price of oats there will be a saving of 25 per cent. Old cart-horses are not worth their keep in winter, while they are at dry meat. For experience shews, that when once a cart-horse begins to fail, whenever he is unable to give due mastication to his dry food, it is better management to knock him on the head, than to waste on him corn and hay. Mr. Marshall then observes, that 80 or 100 guineas are required to purchase four horses, which in six or seven years will be worn out and useless; whereas forty guineas will purchase the same number of oxen, which, after they have worked five or six years, and have been kept at two-thirds the expence of horses, will fetch as much or more than their first cost. Indeed it is a management so obviously eligible, and so glaringly preferable to that of

the use of cart-horses, that few will hesitate a moment which to pursue. In a political light, this management is still more eligible. Oxen, after they have fed the hungry, will themselves become the first of human food. Horses, after they have ate the food of the fatherless, become a nuisance to the animal world; or, buried in a corner, lie a total loss to agriculture and to the community.

CART-LODGE, a small out-house for sheltering carts, waggons, &c. from the weather.

Farmers should be very careful to place their waggons, carts, &c. under proper shelter, when out of use, as they will last twice as long by this means, as they would if exposed in the yard to all weathers; for as they are thus sometimes wet, and sometimes dry, they soon rot, and become unfit for use.

CART-LADDER, a kind of rack, placed occasionally at the trail of a cart or waggon, to make it hold the larger quantity of hay, straw, &c.

CART-RAKE, the cart-track, or furrow made by the wheels of a cart or waggon.

CART-RUT, the same with cart-rake. *See the preceding article.*

CARTWRIGHT, a person whose business it is to make carts, waggons, &c. generally called a wheelwright.

CARUE, or **KERUE**, four. Thus to carue, signifies to grow four, and is generally applied to cream.

CARUNCLE of the eye, the fleshy substance in the inner corner of a horse's eye, next the nose.

CASINGS, or **COW-BLAKES**, dried cows dung, used in several parts for fuel.

CAST, a flight of birds, insects, &c. Thus a cast of bees signifies a swarm or flight of bees.

CATCH-LAND, a name, given to such land as is not certainly known to which parish it belongs; and therefore the minister, who first gets the tithes of it, enjoys it for that year.

CATERPILLAR, a general name for all insects of the butterfly kind, while they continue in their reptile or worm state. They are by some called cankers.

It is well known, that all winged insects pass through a reptile state, before they arrive at perfection. This great change from a worm to a fly, or butterfly, was formerly esteemed a real metamorphosis, or change of one animal into another; but later discoveries have put it beyond all doubt, that the embryo butterfly, when all the lineaments of his parent, is contained within the external cases, or coverings of the caterpillar. When the included animal has acquired a sufficient degree of strength, these coverings are thrown off, and it appears in its genuine form of a fly, or butterfly. It must, however, be observed, that before the creature can free itself from these coverings, it must pass through a state of rest, called by naturalists nymph, or chrysalis state.

Mr. Hitt observes, that there are two sorts of caterpillars, at least those of two colours, which feed upon fruit trees, the one black, and the other green. The black generally make their appearance in March, if the season be dry, upon the pear, apple, and several other trees.

Sometimes great numbers of them are contained in a sort of kel, or web, and, if they are to be come at, should be taken off; for otherwise they will disperse themselves to all parts of the tree, and there feed upon the blossoms, leaves, or their buds, before they are unfolded. After they have lived some time in this active state, they generally conceal themselves in a bunch of leaves, or in a cavity of the rind of a tree, where many of their eggs are hatched the same summer, and become very destructive. There is also reason to think, that some of their eggs are preserved in those places during the winter, as many of them, and some kindled or animated, have been found in old nail holes, and under pieces of dead bark, during the month of February.

The walls should therefore be well washed, and the dwarfs and standard trees well dressed and cleaned at that season.

The green caterpillars, which may, perhaps, be the same with the former at their first appearance, till their colour is gradually changed by living wholly on green food, are never seen so early in the spring as the former; but are very prejudicial to both the young branches and fruit of the apricot, cherry, plum, apple, pear, currant, gooseberry, &c.

They

They are never seen in great numbers together inclosed in a kel or web; but are generally found single, wrapt up in the extremity of a new made branch of the above-mentioned trees, or in a bunch of blossoms of an apple, pear, or cherry tree, and sometimes on an apricot, with a leaf to cover them. Part of their bad effects may be prevented on wall-trees, or dwarfs, whose branches are within reach. If they are at the extremity of a branch, it will appear in a round knob, and they generally eat off the part they had wrapt together, which spoils the branch the next year. When they have inclosed themselves in a bunch of blossoms, or young fruit, then they prove very destructive, by generally eating into all they had joined together, which causes much fruit to drop off soon after, and others when they are more grown.

Some of those which are but slightly eat, will continue upon the tree till the time of gathering; but they never make good fruit, being generally ill tasted, and many times have a white grub within them.

When the caterpillars are first perceived upon the wall or dwarf trees, whether before or after they are wrapt up, a brine should be prepared, and the trees swept all over with a brush or besom dipt in it. This will destroy many of the insects, by beating some off, and killing others. This work should be often repeated, if there be a necessity for it, as there generally is in dry seasons. Perhaps a small engine would be the properest and most effectual instrument for this work.

But gentlemen, who have leisure sufficient, may easily preserve their fruit-trees from the ravages of caterpillars, by carefully inspecting them every-day in the spring; for it will easily be seen when a bunch of blossom-leaves, or young fruit, are joined together by a caterpillar; and, on the first discovery, the leaves are to be separated by the hand, and the caterpillars killed; this will save a young branch or bunch of fruit, which would otherwise have been certainly destroyed. Whoever perseveres in this work will never have much of their fruit destroyed by such insects, which experience has sufficiently demonstrated to be more destructive to the fruit than any other causes that happen in the spring, though many will attribute the scarcity of fruit to blasts or lightnings, or to the branches being sun-burnt, which are the common constructions put upon the effects of these insects.

When standard trees are properly ordered with cutting and dressing, they will not be much subject to be infected with caterpillars; for by taking off the old rind, and cleaning the cankered parts of those trees, many of the insects are destroyed, together with their eggs concealed in those places; and by keeping the branches thin and open, they are more easily shaken off by the winds. *Hitt on Fruit Trees*, p. 265.

Caterpillars not only destroy the leaves and blossoms of fruit-trees, but they also destroy cabbages, and other productions of the garden; and are generally the effect of great drought.

To prevent their numerous increase on trees, gather them off in winter, taking away the prickets, which cleave to the branches, and burn them; but if they get on cauliflowers or cabbages, take some salt water, or strong brine, and water the plants with it, and it will kill the insects: the same effect may be produced by taking some of the caterpillars themselves, bruising them with garlic, and infusing the mixture in water; or you may smoke them with whips of dry straw in March, just as the bud begins to open.

In the summer while they are yet young, when, either through the coldness of the night, or some humidity, they are assembled together on heaps, you may take and destroy them; or you may wash your trees with water, in which worm-wood, tobacco-stalks, and colocintida have been dissolved; or take lime-dust, and when the wind is high, and the trees wet, sprinkle the dust, so that the wind may blow it on the trees. *Mortimer's Husbandry*, vol. I. p. 325.

CATKINS, a name given to such flowers as have an aggregate of summits hanging down, in the shape of a rope, or cat's tail.

CATS'S-FOOT, a name given in some countries to ground-ivy.

CAT'S-TAIL, a round substance growing upon nut-trees.

CATTLE, a general name for beasts of pasture, that

are neither wild nor domestic, but generally confined to those of the ox kind.

Cattle are known to be very advantageous to the breeders of them; and therefore those in middling fortune would do well to apply some part of their time and farms to this useful work: but people in these circumstances, finding it impracticable to make large profits, too often reject, with disdain, the small advantages continually in their power. In vain the wise man informs them that whoever neglects small profits will daily decay; in vain reason dictates, that from a small stock they must be contented with small gain; but that a great number of small profits, which it is easy to multiply by labour, becomes in a short time an object of consideration.

It must not however be imagined, that in order to derive a considerable advantage from cattle, it will be sufficient to have a great number, and to give them the necessary fodder: there are many other circumstances to be attended to, without which it would be in vain to flatter ourselves with the expectation of riches. They are often kept in too narrow a cow-house, from whence many inconveniencies arise. Sometimes they fight, and wound one another. The most voracious starve their neighbours, from whom they carry off all the fodder within their reach; and the injured cows decay insensibly, become languid, or give little milk. In summer the heat incommodes them, a circumstance which makes them grow lean, and diminishes the quantity of their milk. Care must therefore be taken that they have sufficient room in their stalls; that they be cool in summer, and warm in winter. At all seasons let them be dry, for that is a material point. Even in summer, humidity is disagreeable to them, and in winter it chills them. To prevent this double inconvenience, it will be proper to pave the cow-houses on a gentle descent, and to dig a pit to collect all water and stale. By this means the cattle will lie always dry, and the stale be collected for good purposes. Horned cattle sometime contract a habit of licking one another; and that injures so much, that a butcher who perceives it, will give less money for them than for others. They are cured of this habit, by rubbing the places they have licked with cow-dung, the bitterness of which prevents them from pursuing it.

We shall insist on the advantages attending the breeding of young cattle, whatever trouble it may cost, because there is no prudent countryman who is not fully persuaded they are real. To buy what he may have of his own growth is to a farmer no acquisition, but a dissipation: because the land produces no money, which is only to be obtained by the sale of commodities, and very often the purchase of some goods destroys all the profit resulting from the sale of others. It ought, therefore, to be an inviolable maxim, especially with those in narrow circumstances, to spare no pains in improving their stock, not making small estimation of what has cost them no money, but frugal as if they had bought it. By this means, if we except unforeseen accidents, which can never be prevented, they will find wealth flow in upon them annually, though slowly and lay the foundation of a solid fortune. *Journal Oeconomique*.

Fattening and feeding CATTLE. Cattle are bought in to fat at spring, and about Michaelmas. Those you buy in at spring will be fat in July, August, or September, according as they are forward, and you have keeping for them; and those which you buy in August, September, or October, must be either to sell in winter or in spring, and must be forward in flesh to be improved the beginning of winter, and only kept up in flesh during the hard time of winter, either with burnet, hay, turnips, carrots, &c. to be fit for a good market whenever it offers; or they must be young lean cattle, that may by their growth pay for their wintering, and to be fit to fat the next summer. Some upon ordinary land buy in young Welch heifers, which, if they prove with calf, they sell in spring, with a calf by their side for the dairy; and those that are not with calf they fatten: all which ways turn to good account, according as prices fall out; but most commonly all meat, either at Christmas or in the spring, is one third part dearer than in summer: because all have not the convenience either of hay, turnips, &c. to fatten cattle with in winter; and it is but in a few places, especially near London, which is the chief market for fat cattle, that hay can be afforded to fatten them with; for

G g they

they reckon an ox that cost about six pounds, will require about two loads of hay to keep him up all the winter.

For the wintering of cattle, you must about September turn out those you design to keep up for a winter or a spring market, and your cows, that give milk into your rowens, till either snow or a hard frost comes on, as by that means they will need no fodder: but when either snow or frost comes, you must give hay to such cows as are near calving, or those that have lately calved, or that give a great deal of milk, and also to your fattening cattle. This must be done every morning and evening, in proportion to the quantity of rowen you have upon the ground; for the more rowen you have, the less quantity of hay will do, and even the four grass which your cattle would not eat before, will, when the frost hath taken it, become good sweet food for them, and what they will eat with pleasure, if it be not covered so deep with snow, that they cannot come at it. But for your lean cattle, and those that give but little milk, straw will do well enough to fodder them with; only you must observe to give barley-straw first, and the oat straw last, except you value your milk: if you do, give such cows your oat-straw, provided, the quantity of milk they give doth not deserve hay, or hay be scarce with you; for barley-straw will quite dry up the little milk they have, though it is good food for dry cattle. But if your hay and carrots fail you, pour scalding hot-water upon your malt-dust, and, when near cold, give it the cows you design to continue the milk of, and it will cause them to give a great deal, though they eat straw with it. A bushel which costs about three-pence, will be sufficient for a cow in a week. But about London, where they have grains in plenty they give them to their cows in winter, which makes them give a great deal of milk; but is apt to rot them, if given in too great quantities, and for too long a time.

When your rowen is quite eaten up, which will commonly be about February, you must house your milch-cows, which you give hay to all night in your cow-house, and your other cattle in your yard; for which use you should have two yards; one for your cattle which eat straw with racks and other conveniences to fodder them in: observing to feed them often, and not to give them too much at a time; because when they have blown upon it, they will not eat it; both your yards ought to be well sheltered, and made as dry as possible, and a good deal of straw given them to lie dry and warm in, which is a very great advantage to them, and will greatly increase the quantity of your dung.

As to the buying of fat cattle, milch-cows, or lean cattle, experience, and the advice of such persons as understand them, are the best instructors.

For the feeding of land, you may do it with beasts and horses together, or with beasts first, and horses afterwards; and after both put in sheep. But let not your grass be too rank before you feed it; for if you do it will be sour, and your cattle will eat the tops only, so that the other part will lie untouched, and rot upon the ground, as hardly any beast will eat four grass, till the frost hath taken it, except Welch heifers. Observe also where you have inclosures, to be often changing of your cattle from one pasture to another; for by that means you will give your land an opportunity of getting a fresh head, fresh grass being a great help to the feeding of cattle. *Mortimer's Husbandry*, vol. I. p. 231.

Cattle are frequently well fed in winter with rye-straw, mixed with a little hay; with the straw or halm of buck-wheat; with the leaves of white beet; with turnips, the turnip-cabbage, carrots, cabbages, burnet, and the bruised tops of surze; as may be seen under each article. They are also well fed and fatted with the cakes of linseed and rape-seed, or cole-seed. See the articles COLE-SEED and LIN-SEED.

It is really surprising that though plants have been constantly obvious to the eyes of every man, nothing has been delivered down to us in any book, concerning the kinds of plants proper for the different kinds of cattle; the consequence of which inattention frequently is, that the farmer, by not distinguishing and selecting the seeds or proper grasses, fills his pastures with weeds, or which is here equivalent to them, with bad grasses, unfit for the nourishment of the animal he intends to rear.

The illustrious Linnæus in his journey through Dale-

caria in the year 1734, made the first attempt to lay down rules for the farmer's direction in this interesting subject. In his journey he observed, that the horses easily distinguished wholesome from noxious food; for being very hungry, they devoured all sorts of plants, except the meadow-sweet, valerian, lilly of the valley, angelica, loose-strife, marsh-cinquefoil, crane's-bill, hellebore, monkshood, and several shrubs. This gave him a hint to recommend to the curious to apply themselves to examine what plants such animals as live on vegetables will not touch.

The ingenious author of the Swedish Pan, in order to encourage inquiries of this kind, very properly observes, that we admire the wisdom of the Creator, which has made some vegetables absolutely disagreeable to some animals, while they are agreeable to others; and plants, which are poisonous to some, are wholesome to others. This did not happen by chance; it was ordained for wise purposes: for if the author of nature had made all plants equally grateful to all kinds of quadrupeds, it must necessarily have happened, that one species of them having remarkably increased, another species must have perished by hunger, because it would have got into better pasture. In like manner we find it contrived in relation to the plants themselves, which do not all grow in the same country and climate; but every plant has its place, in which it grows more abundantly than elsewhere. From hence we may observe that those animals which live chiefly upon particular plants, abound most in certain places. Thus one animal leaves that which is poisonous to itself, for another animal, which feeds upon it deliciously. Long-leaved water-hemlock will kill a cow, whereas the goat browses on it greedily. Monkshood kills a goat, but will not hurt a horse. Parsley is deadly to small birds, while sheep, hares, rabbits, and swine eat it safely; and pepper is mortal to swine, and wholesome to poultry. Hunger will often drive animals to feed upon plants which nature never intended for them, but after this has happened once, they become more cautious for the future.

Perhaps many of the terrible diseases to which cattle are subject and which has swept away innumerable multitudes, may, in part at least, be owing to the mixture of noxious plants among their food. The great Linnæus was of this opinion: and the following passage in the writings of that admired naturalist is too interesting to be omitted in a work of this kind.

"When I arrived, says he, at Tornea, the inhabitants complained of a terrible disease then raging among the horned cattle, which died by hundreds, soon after their being let into the pastures in the spring. They desired I would consider this affair, and give them my advice what was to be done in order to put a stop to this evil. After a proper examination, I thought the following circumstance worth observing:

"1. That the cattle died as soon as they left off winter fodder, and returned to grazing.

"2. That the disease diminished as the summer came on; at which time, as well as in the autumn, few died.

"3. That this distemper was propagated irregularly, and not by contagion.

"4. That in the spring, the cows were driven into a meadow near the city, and that they chiefly died there.

"5. That the symptoms varied much, yet agreed in this: That the cattle, in grazing indiscriminately on all sorts of herbs, had their bellies swelled, were seized with convulsions, and in a few days expired with dreadful bellowings.

"6. That no man dared to flay the recent carcasses; as they found by experience, that not only the hands of such as attempted it, but their faces too had been inflamed and mortified, and that death had ensued.

"7. The people enquired of me, whether there were any kind of poisonous spiders in that meadow; or whether the water, which had a yellowish tint, was not noxious.

"8. That it was not a murrain was clear because the distemper was not contagious, and because that distemper is not peculiar to the spring. I saw no spiders but what are common all over Sweden; and as to the water, the sediment at the bottom, which caused the yellowness, was nothing but what came from iron.

"9. I was hardly got out of the boat which carried me over the river into the meadow, before I guessed the real cause

cause of the disease; for I there beheld the long-leaved water-hemlock. My reasons for guessing this were the following:

"10. Because in that meadow where the cattle first fell ill, this poisonous plant grows in great plenty chiefly near the banks of the river. In other places it was scarce.

"11. The least attention will convince us, that brutes shun whatever is hurtful to them, and distinguish poisonous plants from those which are salutary by natural instinct; so that this plant is not eaten by them in the summer and autumn, which is the reason that few cattle died in these seasons; those only which eat of it by accident, or were driven to it by extreme hunger.

"12. But when they are let into the pastures in the spring, partly from their greediness after the herbs, and partly from the hunger they had undergone during the winter, they devour every green thing that comes in their way. It also happens that herbs, at this season, are small, and scarcely supply food in sufficient quantity. They are besides more juicy, and covered with water, and smell less strong; so that what is noxious is not easily discerned from what is wholesome. I observed likewise, that the radical leaves were always bitter, and the others not, which confirms what I have just said.

"13. I saw this plant in an adjoining meadow mowed along with grass for winter fodder; and therefore it is no wonder, that some cattle, though but a few, should die of it in the winter.

"14. After I left Tornea, I saw no more of this plant, till I came to the vast meadows near Limingen, where it appeared along the sides of the road; and when I got into the town I heard of the same complaints as at Tornea, of the annual loss of cattle, with the same circumstances.

"15. It would therefore be worth while to eradicate carefully these plants, which might easily be done, as they grow on marshy grounds, and generally by the sides of pools and rivers. But if this cannot be performed, the cattle should not be suffered to go into such places, at least during the spring: for I am persuaded that later in the year they can distinguish this by the smell alone." *Lin. Flora Lapponica.*

Were experiments carefully and judiciously made on the above beneficial plan, we should soon know with certainty what species of animals any pasture affords the best nourishment for. We see, for example, heifers fall away in enclosures, where the meadow-sweet grows in abundance, and covers the ground so that they can hardly make their way through it: while the country people, imagining that the pasture is too rich for them, are quite amazed, and never dream that the meadow-sweet affords them no nourishment: whereas the goat, which stands bleating on the other side of the hedge, is not suffered to go in, though he longs to be browsing upon this plant, which is to him a most delicate and nourishing food. Long experience has taught us, that sheep take up poison in marshy grounds, though no one till lately knew what the particular poison was: yet the spider-wort, the mouse-ear scorpion-grass, the mercury, the sun-dew, the hairy-wood-grass, the lesser spear-wort, and the butterwort, have evidently suspicious marks.

Hence we see, that what makes low grounds so noxious to sheep is not wholly the moisture, but the plants which grow there; for it is remarked by shepherds, that the great danger to sheep is immediately after a fresh spring of grass, when it is natural to think they lick up the young and tender shoots of poisonous plants along with their proper food, not being then able to distinguish the one from the other.

From the observations of this kind the husbandman may form a right judgment of his meadows, and turn into each the animals best adapted to the nature of the pasture.

"The industrious farmer, says the author of the Swedish Pan, may judge from hence, when he sows his meadows with hay-seeds for pasture, that it is not indifferent what kind of seeds he chooses, as the vulgar inadvertently think: for some are fit for horses, others for cows, &c. Horses are nicer in choosing than any other cattle. Plants, whose seeds grow in pods, are particularly relished by them. Goats feed upon a greater variety of plants than any other cattle: but then they chiefly hunt after the extremities and flowers. Sheep, on the contrary, pass by the flowers, and eat the leaves. And again, different animals have different dispositions as to grazing more or less near the ground. The husbandman, who understands these things, and who, in consequence thereof, knows how to lay out his lands, so

as to assign to each sort of cattle its proper food, will necessarily have his flocks and herds healthier and fatter, than he who is unacquainted with these principles. The good manager will also observe the same precautions in the making of his hay: for although many herbs are eaten when dry, which would be refused while green, it does not from thence follow, that they yield good nourishment. Much might be added concerning the propensity of cattle to this or that plant: for example, that sheep delight above all things in the fescue grass, and grow fatter upon it, than on any other kind of grass; that goats prefer certain plants, but, being led by an instinct peculiar to themselves, they search more after variety, and do not willingly stick long to any one kind of food: that geese are particularly fond of the seeds of fescue grass; that swine hunt greedily after the roots of bullrush, while they are fresh, but will not touch them while they are dry." *N. Hasselgren. Amant. Academ. Suec. tom. II.*

If a farmer, says the intelligent Mr. Lisle, intends to graze cattle in a hill country farm, these three things are especially to be regarded; first, to raise a good quantity of French grass for hay and aftermaths. Secondly, to turn a good quantity of hill country meadow into rich pasture, by feeding it, dunging it, and laying on it other manure, to make it fit for raising the bullock or heifer in the spring, when he comes first from hay into grass-lease, and to receive him with a vigorous aftermath, when other grasses, as clovers, and French grass aftermath goes off. Thirdly, to have hovels in your bartons, inclosed with close court-walls, to shelter your cattle in the winter from wind and rain. All these three things are necessary and uniform, corresponding with one another; without them, grazing must be carried on very defectively, and to little profit, by the hill country farmer.

By the methods here prescribed, in order to the fattening of cattle, plenty of French grass hay will enable the grazier to purchase barren beasts before the spring grass comes, when it is most likely they will be cheap, and may be bought to the best advantage, allowing the value of the hay they may eat in consideration with the purchase; and if by winter-hayning some meadow-ground (after it has been kept high in heart by feeding and soiling it) you can early in the spring, by April, or sooner, have a bite to take off such grazing beasts from hay to grass, it will be very advantageous before clovers can be ready, which are seldom so, in the hill-country, till a week or a fortnight in May; and by hayning up such meads for an aftermath, which towards the end of summer are in very good heart, you will support your bullock, and carry him on when the spirit of other grasses fail. Then such cattle as are unfinished being brought to French grass hay, and tied up under hovels or coverings, and within court-walls, will proceed in thriving by being secured from the wind and rain, and the tedious hill-country-rimes, that often continue whole winter days, all which makes cattle brought from grass to pitch, and mashes them out. Besides, if you have not plenty of French grass hay, you cannot make the best of a milch-cow that warps, or of a cow that towards the latter end of winter you may perceive proves barren, or of a fat cow that casts her calf before you kill her. The necessity of French grass hay only, and not of clover hay, is mentioned here, because it is supposed that the hill country farmer, who provides store of French grass hay, will be wise enough not to mow his clover to feed them, in order to improve his lands; for the hill-country farmers have generally so much land for their money, that all they can do is little enough to keep their arable land in such heart as it ought to be in for their profit.

If the foregoing cautions are not observed, the ill consequences that will follow must be such as these: if the first of the three foregoing cautions be disregarded, your cattle cannot at any time of the year be made fat, as they ought to be, and then you must be under the necessity of selling them half fat, of which necessity the buyer never fails to take the advantage; and sell them you must, notwithstanding there be ever so fair a prospect of prices rising in a month or two; and you will commonly find, that you have nothing for the meat they have eat whilst they have been fattening. In the second place, we will suppose that very few will be so unwise as to begin to fat a beast in October with hay, and so to keep him upon hay during the winter: but we may reasonably suppose, that warping beasts, barren heifers, &c. may, and commonly are, begun to be fatted with hay from Christmas, in which case, though hay be

be plenty, yet if an early spring grafs be wanting, such cattle must be kept on it at least to the middle of May; for till then, in the hill-country, it will not give a beast a bite, and then commonly, where the master is at a loss and disappointed, the cattle evidently suffer before he can make the most of them, and, in this case, he will find a beast plainly pitch before he can find a purchaser for him. Again, if early spring-grafs be wanting, you cannot begin summer fattening of cattle, nor buy a barren heifer till towards the middle of May, and then they are commonly very dear: and in the hill-country, from so late a beginning, the summer grafs will hardly fat a beast, the ground falling early off its strength, being generally poor. And then, if you have not a quick growing aftermath treasured up, by keeping such ground as was formerly meadow in good heart for that purpose, it is plain you must again run into the first evil; and, if you have such an aftermath, you may again often want hay in November and December, to finish summer fattened beasts; so that plenty of hay is always necessary, &c. And, lastly, though you have both hay and grafs, if you want winter shelter, the cattle must suffer.

All fattening cattle, whether lambs, sheep, barren cows, or oxen, require a proportionable progression from coarser to better food, as they grow more and more into good flesh; otherwise when half fat they will go back, and you will not without great difficulty raise them again, which will be a great loss; nor will such beef spend kindly.

A gentleman, who would make a good hill-country grazier, ought, against the time he buys in his heifers to take care to be provided with an overplus stock of middling good hay, or of winter vetches, or of barley straw, and autumn grafs, mixed together, layer and layer of each. Be it what it will, it ought to be at least better than barley-straw; for he is to suppose he has bought barren heifers, which have been kept all the winter upon straw: if they have been kept better, for instance, on straw and rowet, there is still the greater reason for him to mend their keeping; and he is, from the time of buying, to consider, that he ought to begin to raise them in flesh; for the better case they are in when turned to spring grafs, they will take to fattening the kinder, and bear their first scouring the better. If he could turn them into the field, for an hour or two in the day where there is a little rowet, it would do well, and to have change of the above dry meats would keep them the better to their stomachs.

Oxen are turned off to fattening at two seasons of the year, which, in several respects, are very convenient. The first is about May-day, when the labour of the ox is pretty well over for the spring season, the spring corn being then generally all sown. The second is the beginning of winter, namely, from the first of October, to the middle of November, when the wheat and winter vetches are generally all sown, and the ploughman's hurry relaxes.

Oxen turned out at May-day will hardly get fat before Christmas, and if not turned out till June, will not be fat till March, April, or May; which again falls out very fortunately, because from Christmas until the latter end of May cow beef is very scarce, and is generally supplied with ox beef; but then it is obvious, when an ox gets half, or three quarters fat by or before winter, he must be supported and carried on by a great quantity of hay, and that very good, for the beast will then grow nice.

Those that are turned from the plough in October and November, ordinary food will serve for some time; for should you lay the best hay before such an ox, then hungry and poor, he will devour more than the profit. The most you can propose by this method is to get him fat by July, instead of September or October; during all which interval of time, heifer-beef will be plenty, and sink the price of ox-beef; so chargeable a method therefore will not quit costs.

What the grazier ought to do in this case is to bring his ox easily and gently into good flesh by a rowet; for which purpose he ought to have hayned up his grounds, and of which rowet he should give him the worst first, except it be of so sour a kind as to want the correction of the winter frosts before he will eat it, of which kind stubble rowet commonly is, and in such case that food must be reserved till then, or rather for young beasts and milch-cows. He ought to give him variety of dry meat along with his rowet, in which he should consult his tooth, by flinging before him, alternately, every sort of good straw, giving now and then a lock of winter vetches, or coarse hay, but of every

thing good in its kind, *i. e.* sweet and well made; and thus the ox ought to be carried on throughout the winter. About the beginning of March he ought to have better hay; not only because the rowet may be supposed to be all gone, but also because the ox, mending in flesh, grows nicer, and will be weary of dry meat, through the tediousness of being foddered so much with it during the winter; therefore his hay must be mended, for not proceeding is going back. Against April, if possible, a short head of grafs should be got for him in your pasture grounds for cow-cattle, by hayning the pasture in February, that he may have grafs along with his hay, as was before observed in the fattening of barren heifers: and against May a head of hop-clover must be in readiness, in the hill country to receive him into his first full grazing; for it is not to be supposed that the meadows of the hill-country, which according to this scheme are to be converted into pasture, can be fit before the first of June to entertain a grazing ox; and it is also to be noted, that in the hill-country, in the month of May, hop-clover will not afford a good bite for an ox or cow, unless the autumnal bud be hayned, and preserved by being fed by sheep: in the month of May, if it should prove a dry spring, the fattening oxen and cows must also have good hay given them, with their hop-clover, if it be short.

Fattening in the hill-country, especially if you give your cattle hay in the winter, is more chargeable than in the vale; not only because hay is dearer there, but also because the winter season begins a month sooner, and continues a month later in the former than in the latter. The farmer in the hill-country must likewise, by forcing nature as it were, provide rowet and several sorts of grasses in their due order, exactly accommodated to the season of the year, besides winter meat, &c. Whereas all may be procured by the latter in the natural course, with very little care and trouble.

It will be necessary to observe, that every hill-country grazier goes to work without his tools who does not lay down from fifty to an hundred acres of land proper for it, with French grasses, not only on account of making up the deficiency of the meadows not laid down to pasture, being converted to other uses, but also to answer many other demands. *Lisle's Observations in Husbandry, vol. II. p. 18.*

A stalled ox in the winter, if he be kept to hay only, will eat at least a load every two months. *Ibid. p. 5.*

Fourteen pounds weight of hay is the constant allowance on the road to every fat beast that is drove to London; they that entertain cattle sling fourteen pounds of hay for each beast into the rack in the evening when they come into the inn, which is to serve also next morning for their breakfast; so that half a tod, or seven pounds of hay, is supposed sufficient for a fat ox's bait at night, and the same in the morning. *Ibid. p. 9.*

For the manner of feeding and fattening cattle with cabbages, carrots, turnips, turnip-cabbages, &c. See the articles CABBAGE, CARROT, &c. and plate III. for a cattle shed.

Mr. Marshall, who treats largely on the subject of cattle, in his Rural Economy of Norfolk, says, "In treating of this species of live stock, it will be proper to consider, separately,

1. The present breed of cattle, in this district, is not less peculiar to the country, than its breed of horses was formerly (*see* HORSES), and is strongly marked with the same leading characters.

The native cattle of Norfolk are a small, hardy, thriving race; fattening as freely, and finishing as highly, at three years old, as cattle in general do at four or five.

They are small-boned, short legged, round-barrelled, well-loined, thin-thighed, clean-chapped; the head in general fine, and the horns clean, middle-sized, and bent upward: the favourite colour a blood-red, with a white or mottled face.

The breed of Norfolk is the Herefordshire breed in miniature; except that the chine and the quarter of the Norfolk breed are more frequently deficient.

This, however, is not a general imperfection. I have seen Norfolk spayed heifers sent to Smithfield, as well laid up, and as full in their points, as Galloway or Highland "Scots" usually are; and if the London butchers be judges of beef, there is no better fleshed beasts sent to Smithfield-market.

These two qualifications, namely, the superior quality of their

their flesh, and their fattening freely at an early age, do away every solid objection to their size and form. Nevertheless, it might be advisable to endeavour to improve the latter, provided those two far superior qualifications were not by that means injured. But it might be wrong to attempt to increase the former, which seems to be perfectly well adapted to the Norfolk soil.

The medium weight of a well-fatted three-year old is forty stone (of fourteen pounds each).

Bulls of the Suffolk polled breed have, at different times, been brought into this district: and there are several instances of the Norfolk breed being crossed with these bulls. The consequence is, an increase of size, and an improvement of form: but it is much to be feared, that the native hardiness of the Norfolk breed, and their quality of fattening quickly, at an early age, are injured by this innovation; which was first introduced by gentlemen, who, it is probable, were unacquainted with the peculiar excellency of the true Norfolk stock; and the mongrel breed, which has arisen from the cross, yet remains in the hands of a few individuals.

A few years ago, a Highland Scotch bull was brought into this neighbourhood, by a man who stands high in the profession of grazing, and who has crossed his own stock, of the true Norfolk breed, with this bull. The produce of this cross proves, that if the genuine breed can be improved, by any admixture of blood whatever, it is by that of the "Highland Scot." The chine is, by this cross, obviously improved; and the hardiness, as well as the flesh, and proneness to fat at a certain age, cannot receive injury from this admixture. The only thing to be feared from it is, that the stock will not fat so early, as will that of the genuine breed; and, if the opinion of the oldest, gravest, and I had almost said, the best farmer in the district has any weight in this case, this evil effect is much to be apprehended: he is clear in that a "Scot" does not fat kindly even at three years old, much less at two; at which age many hundred head of cattle are annually fatted in this country.

The fact appears evidently to be, that the Norfolk husbandmen are in possession of a breed of cattle, admirably adapted to their soil, climate, and system of management: and let them cross with caution, lest by mixing they adulterate; and, in the end, lose, irretrievably, their present breed of cattle; as their forefathers, heretofore, lost a valuable breed of horses; the loss of which can, now, be only lamented.

If, through the laudable spirit of improvement, attempts be made with foreign breeds, they ought to be made with caution. But, from what I have seen and known of the Norfolk stock, and what I have since seen of the improvement of the breed of cattle, in other counties, it appears to me, evidently, that nothing more is wanted to improve the form of the present breed of cattle in Norfolk than a due attention to the breed itself.

While such cows, and such bulls, as I have sometimes seen, are suffered to propagate their deformities, no wonder some valuable points should be lowered. But if, in the reverse of this unpardonable neglect, men of judgment and enterprise would make a proper selection, and would pay the same attention to the Norfolk breed as is paid to the long-horned breed, in the midland counties, and to the short-horned in the north of Yorkshire; every point might beyond a doubt be filled up, and the present valuable qualities be at the same time retained.

But the great cause of neglect in the breeding of cattle in Norfolk is, that men of judgment and spirit rather choose to purchase of the Scotch drovers, or of their poor and industrious but less judicious neighbours, than to go themselves through the tedious round of rearing. However, if we consider the present universal scarcity of cattle (1786), and that the Scotchmen, through recent improvements of their plan of husbandry, are now enabled to fat a part of that stock, which formerly they drove wholly to the southward; it seems highly probable that the Norfolk grazers will, henceforward, find their advantage in increasing and improving their own breed; and they may rest assured, that he who first sets about its improvement will have it in his power to keep the lead; and reap, of course, the highest advantage.

The prime intention of keeping cows in this country is the rearing of young stock; the produce of the dairy, unless in the neighbourhood of large towns, being a secondary object.

But the number of cows kept, even by the rearing-farmers, is few: eight or ten may be considered as a middling dairy of cows upon a middle-sized farm; I mean on the east side of the county.

In West-Norfolk, especially on the marsh land side towards Cambridgeshire, large dairies of cows are kept, for the purpose of making butter, which is sent weekly to London under the denomination of Cambridge butter.

This is a fortunate circumstance to the East-Norfolk breeders, who draw an increase of rearing-calves from that quarter of the county: whose dairymen, in their turn, are benefited, in being by this means enabled to get rid of their calves, at an early age; jobbers making it a business to transfer them from one side of the county to the other.

By this means, and by buying up the calves of cottagers, farmers, and gentlemen of the neighbourhood, who do not rear their own, an East-Norfolk breeder is able to rear a greater number of calves than the number of his cows amount to.

Ten or twelve calves may, perhaps, be considered as the medial number reared at present, on a farm of one hundred and fifty pounds to two hundred pounds a year.

In the neighbourhood of Norwich and Yarmouth, cow-keeping is frequently applied to the fattening of calves for the ped-markets.

Also, in the neighbourhood of these and other towns, but-ter becomes an object of sale. Mr. Marshall further says,

Rearing cattle calls for a threefold division; viz.

Calves,

Yearlings,

Two-year-olds.

The rearing of cattle is become, in my opinion, a subject of the first importance to this country: an universal and growing scarcity of neat stock is experienced, more or less, throughout the kingdom. I have therefore paid more than common attention to the rearing of calves (the first and most difficult part of the business) in this district: not only as being a primary object in the East-Norfolk system, but because the practice here is, in many respects, peculiar to the country.

The number has already been mentioned in general terms: it varies, however, with the quantity of meadow or other natural grassland belonging to a given farm; and sometimes, but not always, with the time at which the cows happen to come-in.

Some farmers "bring up" all the year round;—rearing every calf he has dropt. Others rear in winter, only; fattening his summer calves for the ped-markets; or, at a distance from them, for the butcher. Norfolk farmers, in general, begin early in winter to rear their calves: some so early as Michaelmas; in general, if their cows come in, before Christmas: not only as being fully aware of the advantage of rearing early; but in order that they may rear as many of their own calves as possible; "drove calves" being always hazardous, and sometimes scarce.

No distinction is made as to sex: males and females are equally objects of rearing, and are both, occasionally, subjected to castration; it being a prevailing custom to spay all heifers intended to be fatted at three-year-old; but such as are intended to be finished at two-years-old are, I believe, pretty generally left "open:" as are, of course, such as are intended for the dairy.

There are two reasons for this practice: they are prevented from taking the bull too early, and thereby frustrating the main intention; and by this precaution they lie more quietly—are kept from roving—at the time of fattening. This may be one reason why spayed heifers are thought to fat more kindly at three-years-old, and to be better fleshed, than open heifers.

The method of treatment depends in some measure on the time of rearing: winter calves require more milk than the later-dropt ones do.

The general treatment of calves dropt at Christmas may be said to be this: sucks, twice a day, the first fortnight: has the pail, twice a day, for the next month or six weeks: and once a day, for a month or six weeks longer:—with hay in a rack, and turneps in a manger; and, sometimes, with oats and bran among the turneps: which last, after a calf has taken freely to them, serves as both meat and drink.

In this consists the chief peculiarity of the Norfolk method of rearing calves: which may be said to be with milk and turneps: the last a species of food, which, in every

other part of the kingdom, is, I believe, entirely neglected, or unthought of.

As soon as the weather gets warm enough, the calves are turned out, in the day, among the fattening bullocks, or on to a patch of turneps, or upon a piece of wheat, or a forward grass-piece, and housed again at night: until the days growing long, and the nights warm, and the clover and dandelion have risen to a full bite, they are turned out altogether; and continue to have the first bite of every thing, which is good and palatable to them, throughout the summer.

This, may be called the general treatment of calves dropt at Christmas; but the managements of no two farmers are exactly the same. The lattermath and stubbles being finished, the yearlings—provincially “buds,”—are put to turneps: either as followers to the bullocks, or have some fresh turneps thrown to them: in either case, they sleep in the par-yard, and generally have a separate par allotted them; though sometimes they are parred with the two-year-olds.

In the yard, the best of the “stover” is allowed them, and, perhaps, a little ordinary hay: it being a maxim, pretty generally adopted among good farmers, to keep their young stock as well as they can the first winter.

In spring, and summer, they follow the bullocks, and run in the meadows; or, if these be wanting, are sometimes sent out to summer grass in the marshes or grazing-grounds.

The two-year-olds, run in the stubbles and broken grass till Christmas, or until turneps can be spared them; when they generally follow the bullocks. In winter, they are always “parred” at night; sometimes with the cows; sometimes with the buds; sometimes alone. Good farmers generally keep them separate:—if parred with the buds, they rob them; if with the cows, they are liable to be “horned,” and are never at rest; except while the cows are eating up the best of the fodder.

Some farmers, when turneps run short, “put out” their two-year-olds in winter; and others when they are plentiful, “graze,” that is, fat their two-year-olds.

In general, however, they are “kept over-years,” on meadows or lays, or are sent to the marshes or grazing-grounds, as situations and circumstances point out; and, at Michaelmas, are put to turneps as fattening-cattle.

The agistment price for two-years-olds, from May-day to Michaelmas, varies with the keep.

Bullocks is the grand object to which every part of the Norfolk husbandry more or less tends, and which distinguished it, from the husbandry of all other countries.

The practice of fattening bullocks on turneps is, however, now beginning to creep into every part of the kingdom: but it may be said to be still in a state of infancy every where, except in Norfolk; and an accurate account of the practice of this parent-country cannot fail of being useful to every other turnep-land district.

Impressed with this idea, I spared no pains, nor let slip any opportunity, of making myself acquainted with the subject. The grand divisions of the subject are,

The species of bullocks fatted.

The method of obtaining them.

The method of fattening them.

The only species of cattle fatted in East-Norfolk may be said to be home-breds and Scots. Some Irish beasts have, at different times, but not regularly, been brought into the country, and have generally done very well. In West-Norfolk, great numbers of Lincolnshire and Yorkshire oxen were formerly, and some few, I believe, are now, fatted; but in this district they have always been considered as much inferior to the Scotch and home-bred stock.

Home-breds consist of steers, spayed heifers, open heifers, barren cows, running calves.

The last is a species of fattening cattle peculiar, perhaps, to this country. They are calves, which are suffered to run with their dams until they be a twelvemonth or more old: the cow being all the while at head-keep, of which the calf partakes, as well as of the milk of its dam: which, herself, in the mean time, generally gets fat enough to be sent to Smithfield, with her calf (perhaps, as heavy as herself) by her side.

The Scotch cattle fatted in Norfolk consist of Galloway Scots; other Lowland Scots; Highlanders; Isle of Skys.

The Galloway Scot is large, thick, short-legged, mostly hornless, and of a black or brindled colour: the flesh well grained; and the form altogether beautiful: chine

full; back broad and level; quarter long and full at the nache; round barrel; deep girth; and the bone, head, and chap, in general, fine.

This I apprehended is the genuine original Galloway Scot; and a principal part of the bullocks brought into Norfolk under that name are of this description: but the droves are generally adulterated with a mongrel sort; the produce of a cross with the long-horned breed.

This species of adultery is said to be committed and encouraged by the nobility and landed gentlemen of the countries they are bred in; but the fact appears to be, that they have already one of the finest breed of cattle in the world upon their estates; and it behoves them to hand it down to posterity as pure at least as they received it. In this age of improvement, it might be laudable to endeavour to improve it to the utmost: not, however, by foreign admixtures; but by giving the most beautiful females to the most beautiful males of their own breed. They appear to me to have much to lose, but nothing to gain, from crossing, not even with the present long-horned breed of the inland counties.

This species of Scotch cattle appears to be originally of the county of Galloway, which forms the southern extremity of Scotland; but they are now, it is said, propagated in other parts of the Lowlands, especially in the rich-land countries of Lothian, in the neighbourhood of Edinburgh. I have known them fatted to eighty stone; and have been informed, from authority which I have no reason to doubt, that they have been known to reach near one hundred stone (of fourteen pounds each).

Lowland Scots are the ordinary breed of black-cattle, in the Lowland counties, size below the Galloways, and appear to be a mixture between these and the Highland Scots. Sixty stone is a good weight for a Lowland Scot. His form and inclination to fat partake of the Galloway breed: the former, however, is seldom so near perfection as is that of a true Galloway Scot. Lowland Scots are some of them horned, some of them polled: their colour black, or brindled, or dun.

Highland Scots. This seems to be a distinct breed. The size is beneath that of the Lowland Scots: forty to fifty stone is the ordinary weight of a Highland Scot. In form, flesh, and fattening quality the Highlanders resemble much the Galloway Scots; except that their backs in general are coarser, their bone proportionably larger, and in that they have, in general, but not always, horns, of the middle size, and mostly bent upward, like those of the Welsh cattle but finer.

In general appearance there is a strong resemblance (their horns apart) between the Highland Scots and the black cattle of North-Wales; but with respect to flesh and fattening quality, the main objects, the comparison is greatly in favour of the Scotch breed which the gentlemen of North-Wales are said to fetch annually out of Scotland, or to buy them up at the English fairs, to be fatted for their own tables.

The Isle of Sky appears to be only a variety of the Highland breed; contracted by soil, or climature, or both. They are, in point of size, the lowest in the gradation. But with regard to flesh, fattening, and growth while fattening, they may be said to stand foremost. I have known an Isle of Sky Scot, brought at two years and a half old for less than forty shillings, reach, in about twenty months, to forty five stone.

At that age their growth in England is astonishing; owing, perhaps, not more to their nature than to a change of climature, and a change of food. Much, however, depends upon their age. If they be intended for immediate fattening, four years old is the properest age. An Isle of Sky or a Highland Scot at two or three years old will grow, but he will not fat; at five or six he will fat, but he will not grow, while fattening, equal to a four-year-old bullock. At this age the weight of Isle of Sky Scots, when fat, varies from twenty to forty stone.

These are the four species or varieties of cattle which are brought by the Scotch drovers to the Norfolk fairs, and which are bought up and fatted by the Norfolk farmers, under the foregoing names. There may be other breeds and admixtures of cattle propagated in Scotland; but, not being sent to this market, they are foreign to the present subject.

The method of obtaining bullocks for fattening, is either by rearing, or by purchase.

Some farmers rear all their own fattening-stock: others purchase

purchase the whole. But the more general practice is to rear part, and buy in part. Much depends upon situation; but more, perhaps, upon judgment: and still more, perhaps, upon an ample and regular supply of the means of purchase. It is allowed, that the affluent fortunes which were formerly made by some few Norfolk farmers, were chiefly acquired through a superior skill in the purchase of stock, seconded by a full supply of money; by which means they were always able to time their purchase to the best advantage. But in men of inferior judgment, and who have not money at their command to purchase when the price of stock is low, it is undoubtedly prudent to rear the whole, or a principal part, of their own stock; for, in doing this, they travel a beaten track, and tread on sure ground.

The purchase of home-breds is chiefly at the fairs; or at the breeder's houses; or on at the Castle-hill at Norwich, where there is a weekly market; sometimes pretty full of different sorts of live stock.

The purchase of Scots is, in this district, chiefly at the fair of St. Faith's, a village near Norwich; to which the Scotch drovers bring annually great numbers.

These Scotch dealers have a succession of fairs, which keep them some months in the country; during which time a continued stream of cattle is kept flowing from its various sources in Scotland to its general efflux: which is judiciously removed from place to place, that the diffusion may be more regular and easy.

East Norfolk, as observed above, is principally supplied at St. Faith's. The northern hundreds sometimes draw an additional supply from Hempton-Green; and the southern ones from Haleworth and Hoxone, which, with the other fairs in Norfolk, lie within the reach of the Norfolk farmers.

The Highlanders and Isle-of-Skys are chiefly or wholly oxen; but the Galloway, and other Lowland Scots have a mixture of spayed heifers; a species of fatting cattle which is coveted by judicious graziers.

The most common age is four years old; but many of the Scotch cattle brought to these fairs are probably much older: some of them have been worked: even some of the Highlanders are said to be worked at the collieries. There are also many three year olds, and some two years old or under. These are bought to be kept over year in the meadows, marshes, and grazing grounds.

For the same purpose, two year old home-breds are also purchased, the first day of these and at other fairs.

But, for immediate fatting, the desired ages are three years old for home-breds, and four years old for Scots.

In the method of fatting, the first thing to be considered is, the proportion of bullocks to a given quantity of turneps. This depends on the size of the bullock, and the quality of the turneps. The general calculation is a middle-sized bullock to an acre of good turneps. Taking turneps on a par, a fatting-bullock and a follower, come, perhaps, nearer the real proportion.

The time depends on the growth of the turneps and the possession of the bullocks: the home-breds are usually put to turneps about Michaelmas; the Scots, as soon as they are purchased. It is observable here, that notwithstanding a Scotch bullock, especially of the smaller kind, never saw, perhaps, a turnep, yet, when thrown to abroad, in company with two or three home-breds, he generally soon learns to break his turneps. Some particular bullocks, however, will receive a check before they take to them.

The place for fatting bullocks on turneps is either the field, the yard, sheds, or hovels.

The first requires least attendance and attention, and is highly beneficial to light land: the second makes a great quantity of manure, but a waste of stover: the last requires less litter; but incurs a greater portion of labour.

In a dry, open season, bullocks at turneps do best abroad; in wet, pinching weather, best under cover.

Out of these established facts arises an obviously eligible plan of management, where circumstances will admit of it. In autumn, so long as the weather continues moderate, let bullocks remain abroad; but, whenever it sets in very wet, or very severe, take them up under cover; and there let them remain until they be finished, or until the warmth of spring calls them abroad again.

But the most eligible method of fatting depends on a variety of circumstances: these Mr. Marshall says, are

The soil and situation;

The conveniencies in the yard;

The season; and

The species of stock to be fatted.

Cattle which have been accustomed to lie abroad in a severe climate, will stand the winter in the field better than those which have been used to a sheltered yard, in a warmer climate.

No general plan of management can, therefore, be laid down. All that can be done is, to point out the various modes of use, and leave every man to consider well his own particular circumstances, and make his election accordingly."

In Mr. Marshall's Rural Economy of the Midland Counties, he gives the following directions on the subject of cattle and livestock:

"In the midland district, the four principal species are found in peculiar plenty, and in a singular state of improvement. The other three I shall pass over. Rabbits cannot be deemed an object of the rural economy of this district; and with regard to poultry and bees, nothing sufficiently striking has occurred to me in it, to require particular notice: except that game fowls are here in the first estimation, as a species of poultry; as producing more eggs, and being themselves better fleshed and better flavoured than fowls in general.

"Therefore this division of the present work will be confined to horses, cattle, sheep, swine.

"A country that has deservedly obtained so much credit by its management of live-stock, especially the three species first mentioned, and which has carried on the improvement of the several species, more particularly those of cattle and sheep, with a spirit unknown before, and has raised them to a height unattained, perhaps, in any age or nation, is entitled to every attention. It would indeed be unpardonable, and altogether inconsistent with this undertaking, to pass over its practice in a superficial manner. The spirit of improvement is now in the zenith, and the improvement itself, taken in a general light, is now, probably, at its height. The breed of horses in this district is allowed to be on the decline. Its breed of cattle are probably at its height; and its sheep are at present so near perfection, that it is not probable they should hereafter receive much improvement. Beside, the grand luminary of the art has passed the meridian, and though at present in full splendor, is verging toward the horizon.

"It must not however be understood, by those who are not locally acquainted with this district, that Mr. Bakewell, though he has been long, and most deservedly, considered as the principal promoter of the art of breeding, and has for some length of time taken the lead, is the only man of distinguished merit in this department of rural affairs, in the district under survey. It abounds, and has, for many years, abounded with intelligent and spirited breeders. I could mention some fifteen or twenty men of repute, and most of them men of considerable property, who are in the same department, and several of them eminent for their breeds of stock.

"Nevertheless, it must be and is acknowledged, that Mr. Bakewell is at the head of the department; and whenever he may drop, it is much to be feared, and highly probable, that another leader, of equal spirit, and equal abilities, will not be found to succeed him.

"Having said this, however, it will be proper to apprise my readers still farther, that the following account must not be understood as a detail of the practice of Mr. Bakewell; but as a more enlarged register of the practice at present established in the midland counties. For, notwithstanding I have been repeatedly favoured with opportunities of making ample observation on Mr. Bakewell's practice, and have as repeatedly been favoured with his liberal communications on rural subjects, it is not my intention to deal out Mr. Bakewell's private opinions, or even to attempt a recital of his particular practice, any other than as it constitutes the valuable part of the district under survey.

"In registering this practice, it will be requisite, beside a separate account of the several breeds and their improvement, to describe the methods of breeding and rearing each species, and to detail the business of grazing, and the dairy management.

"To give full scope to the enquiry, it will be necessary to take a separate view of each species of live-stock, that are here the objects of attention, and previously to convey some general ideas respecting the principles of improvement

ment which have here been laid down, and the means by which they have been successfully and rapidly raised into practice. The subject is new, at least to this work, and will therefore require a degree of attention adequate to its importance.

The most general principle is beauty of form; a principle which has been applied in common to the four species. It is observable, however, that this principle was more closely attended to at the outset of improvement (under an idea, in some degree falsely grounded, that beauty of form and utility are inseparable) than at present, when men who have been long conversant in practice, make a distinction between a useful sort and a sort which is merely handsome.

"The next principle attended to is a proportion of parts, or what may be called utility of form, abstractedly considered from the beauty of form: thus, of the three edible species, the parts which are deemed offal, or which bear an inferior price at market, should be small, in proportion to the better parts. This principle, however, appears to have been differently attended to in different species; and will require to be examined, in taking the separate views of each species.

A third principle of improvement, which has engaged the attention of the midland breeders, is the texture of the muscular parts, or what is termed flesh; a quality of live-stock which, familiar as it may long have been to the butcher and the consumer, has not, perhaps, been attended to by breeders, whatever it may have been by graziers, until of late years in this district; where the flesh is now spoken of with the same familiarity as the hide or the fleece; and where it is clearly understood, that the grain of the meat depends wholly on the breed, not, as has been heretofore considered, on the size of the animal.

"It appears however, in the Practice of Yorkshire, of late years, that circumstances led the breeders of that country to pay some attention to the flesh of cattle; and, I have been informed, by a gentleman conversant in the Herefordshire breed of cattle, that similar circumstances took place, and probably about the same time, in that quarter of the island.

"But the principle which at present engrosses the greatest share of attention, and which, above all others, is entitled to the grazier's attention, is fat, or rather fattening quality: that is, a natural propensity to acquire a state of fatness at an early age, and, when at full keep, in a short space of time: another quality which is found to be hereditary, depending, in some considerable degree at least, on breed, or what is technically termed blood; namely, on the specific quality of the parents.

"Thus it appears, that the midland breeders rest every thing on breed; under a conviction, that the beauty and utility of form, the quality of flesh, and its propensity to fatness, are, in the offspring, the natural consequence of similar qualities in the parents: and, what is extremely interesting, it is evident from observation that these four qualities are compatible, being frequently found united, in a remarkable manner, in the same individuals.

Without admitting, or endeavouring to confute, in this place, that the four qualities here explained are the only ones necessary to the perfection of the several species of live-stock now under review, we pass on to the means whereby those principles have been applied, in attaining the degree of perfection at present observable in the district under survey.

"The means of improvement, in the established practice of the kingdom at large, are those of selecting females from the native stock of the country, and crossing with males of an alien breed; under an opinion, which has been universally received, that continuing to breed from the same line of parentage tends to weaken the breed.

"Rooted, however, as this opinion has been, and universally as that practice has prevailed, there is little doubt of the fact, that the superior breeds of stock of this district have been raised by a practice directly contrary; that of breeding, not from the same line only, but the same family: a practice which has now been so long established, as to have acquired a technical phrase to express it. Breeding *in-an-din* is as familiar in the conversation of midland breeders, as *crossing* is in that of other districts. The sire and the daughter, the son and the mother, the brother and the sister, are, in the ordinary practice of superior breeders, now permitted to improve their own kind; and through

the assistance of this practice, as will appear, the bold leader of these improvements produced his celebrated stock.

"The argument held out in its favour is, that there can be only one best breed; and if this be crossed, it must necessarily be with an inferior breed; the necessary consequence of which must be an adulteration, not an improvement.

"How far this novel practice may, in a general light, be considered as superiorly eligible, would be improper to be discussed in this place; in which I mean to convey only a general idea of the present practice of the district; in order to save repetition, and to enable the reader to follow me through the several parts of the enquiry with greater ease. To this intent, it must likewise be understood, that although much has probably been done by breeding in-and-in, much also has been done by crossing; not, however, by a mixture of alien breeds, but by uniting the superior branches of the same breed.

"The degree of excellency obtained, however, through these means, is not more remarkable than the rapidity with which the improvement of the several breeds has been carried on and extended, not over this district only, but to various parts of the island.

"But these circumstances likewise have arisen principally out of a mere point of practice, which, though not peculiar to this district, is no where, I believe, equally prevalent (except in Lincolnshire) and enters not, in any degree, into the practice of the island at large; in which breeders of every class rear or purchase their male stock.

"Here, on the contrary, breeders mostly hire them by the season, of a few leading men in the line of breeding males for the purpose, returning them at the end of the season to their respective owners, who, during the time of letting, have their shows or exhibitions, to which dairy-men, graziers, and stallion-men repair, to choose and hire males for the coming season.

"Beside these private exhibitions, there are, annually, public shows in different parts of the district, for the same purpose: thus Ashby has its stallion show, Leicester its show of rams, and Bosworth has its show of bulls; not however merely for letting, but likewise for sale.

"The practice of letting male stock, by the season, is a department of rural affairs not known to the kingdom at large, forming a new subject in the rural science.

"In practice, however, it generally happens that a breeder of male stock; provincially, for want of a better term, called a tupman, is likewise a dairyman, and frequently a grazier; Mr. Bakewell being the only man in this district who confines his practice solely to breeding and letting.

"It must not however be understood that dairymen and graziers universally, throughout the district, hire their males of these superior breeders. Many of them still go on in the old track of rearing, or of purchasing of each other, agreeably to the practice of other districts.

"The practice of letting out male stock by the season being a subject new to this undertaking, it will be proper in this place to examine it with due attention.

"Its origin does not clearly appear. It has probably arisen in the letting of stallions for the spring season. A domestic industrious man has a good horse; but is too attentive to the ordinary business of his farm, to follow him every week to three or four markets, and too diffident to set him off to advantage, and to enter into contests and unavoidable squabbles with stallion-men; while, to a man of more leisure and less modesty, a loose calling is most agreeable. Thus both parties are served: the latter, by receiving a certain sum and his horse again; the hirer by getting a greater number of mares than the owner could have got. This mode of disposal would of course give a loose to the breeding of stallions; for the breeder not only got rid of the disagreeable part of the business, but, if his own neighbourhood were overstocked, he could by this means send them to other districts. Similar circumstances might lead to the letting of bulls and rams.

"Be this as it may, the letting of rams has long been the practice of Lincolnshire; and the letting of horses has probably been practised, on a small scale, in many districts. But the letting of male stock, viewed in the general light we are now viewing it, was never applied, generally, to the three principal species, until of late years in this district. Mr. Bakewell, though he cannot be deemed the projector, has certainly been the principal promoter of this branch of rural business.

The effect of letting male stock has probably been greater than was foreseen. The great improvement which has been made in the stock of this district is striking, but may be accounted for in this practice. A superior male, the best for instance, instead of being kept confined within the pale of his proprietor, or of being beneficial to a few neighbours only, became through this practice a treasure to the whole district; this year in one part of it, the next in another. Hence, even one superior male may change considerably the breed of a country; but in a year or two his offspring are employed in forwarding the improvement. Such of his sons as prove of a superior quality are let out in a similar way; consequently the blood in a short time circulates through every part, and every man of spirit partakes of the advantage.

The breed of the midland counties, is the longhorned: a breed which appears to have occupied, a length of time, the central parts of the island.

In a general view, the old stock of the country, notwithstanding the singular efforts that have been made toward improvement, remains with little alteration. Each division of the district has still its own breed, distinguishable from that of the other divisions. There is a similar distinction between the breeds of Staffordshire and Derbyshire, for instance, as there is between those of Herefordshire and Gloucestershire. The breeds of other divisions of the district have characteristics sufficiently strong to show, that the longhorned breed of cattle have, during some length of time, been the prevailing stock of the country; and that, viewing the district at large, Leicestershire excepted, no radical change, nor any obvious improvement or alteration, has yet taken place. A striking instance, this, of the slow progress with which improvements in this department of rural economy are made, even when carried on with every advantage.

But notwithstanding the whole stock may still be said to be in possession of the country, every division of it wears, at present, strong marks of improvement. Warwickshire, Staffordshire, and Derbyshire, may contend for some share of this beneficial change; and in Leicestershire, the improved breed may be said to have gained, already, a degree of establishment.

The history of this extraordinary improvement would be interesting and useful; as it might furnish useful ideas to the improvers of other breeds. All I am able to give is a sketch.

Craven in Yorkshire has long been celebrated for a superior variety of the longhorned breed of cattle. From this source, it is well known, the Lancashire cows have been, and, I believe, still are drawn:—the flower of these celebrated cows originating in Craven-heifers.

Formerly, the Craven breed seems to have extended, in a similar way, into Westmoreland, also an adjoining county. From Westmoreland, bulls and heifers of this breed found their way into the midland counties. The present improved breed is traceable, by the indisputable evidence of many persons still living, to what was here called the “true old Westmoreland sort.”

It is generally understood, here, that through this breed, and some fortuitous circumstances, rather than from any fixed principles of improvement, Mr. Webster of Warwickshire (of Canley near Coventry) became, some forty or fifty years ago, possessed of a superior breed of cattle; and continued, during many years, the leading breeder of the midland counties. I have, indeed, heard it said, by a man who has himself been a breeder of some eminence, “that Mr. Webster had the best stock, especially of *beace*, that ever were, or (he believed) ever will be, bred in the kingdom.”

To this bold assertion, however, I am not ready to give full credit. I register it merely as an evidence of the high degree of excellency which Mr. Webster acquired. It is improbable that, after twenty or thirty years anxious attention, not of one man only, but of several, the breed, though excellent then, should not, since, have received some degree of improvement.

Be this as it may, Mr. Bakewell is well known to have got the lead, as a breeder of cattle, through the means of the Canley stock. His celebrated bull Twopenny, that may be said to have first given the lead to Mr. Bakewell, was out of a cow, purchased, when a heifer, of Mr. Webster, and was got by a bull from Westmoreland; a bull purchased in Westmoreland.

Mr. Fowler of Oxfordshire (of Rollright on the borders of Warwickshire), whose stock is at present in the first estimation, owes the superiority of his breed to the same source. His cows are of the Canley blood; and his bull Shakespear, the best stock-getter, I believe, the midland district ever knew, was got by a grandson of Twopenny, (out of a daughter of Twopenny) and a cow of the Canley blood.

Mr. Princep of Derbyshire (of Croxall in this district) acknowledges to have raised his present noble herd of cows, the first dairy of longhorned cows in the kingdom, I believe, for form and size taken jointly—from a cow by the name of Bright; purchased of the late Mr. Chadwick of Castle Bromwich: which cow was got by Mr. Webster's Bloxedge bull, that is spoken of here, as being the purest fountain of the Canley blood.

The present state of the improved breed of the Midland counties, which might well be distinguished by the Canley breed, is the following:

Mr. Bakewell is in possession of many valuable individuals, males and females. His bull D. generally known by the name of the “mad bull,” is a fine animal; and is a striking proof of the vulgar error, that breeding in and in, weakens the breed. He was got by a son of Twopenny, out of a daughter and sister of the same celebrated bull; she being the produce of his own dam. Nevertheless, D. is the sire of Shakespear, by another daughter of the same bull, and is probably the most robust individual of the longhorned breed; while D. himself, at the age of twelve or thirteen years, is more active, and higher mettled, than bulls in general are, at three or four years old.

This has long been esteemed Mr. Bakewell's best bull; and has been kept, principally, for his own use. He was never let, except part of a season to Mr. Fowler; but has had individual cows brought to him, at five guineas a cow.

Mr. Bakewell's cows are of the finest mould, and the highest quality: and his heifers beautiful as taste could well conceive them: clean and active as does. Mr. Bakewell's exhibition of cattle would gratify the most indifferent spectator, and could not fail of being highly satisfactory to every lover of the rural science.

Mr. Fowler's cattle are, at present, in the highest repute. His cows have long been considered as of the first quality:—of the best Canley blood. And his bull Shakespear, already mentioned, has raised them to a degree of perfection, which, in the opinion of the first judges, the breed of cattle under notice never before attained.

This bull is a striking specimen of what naturalists term accidental varieties. Though bred in the manner that has been mentioned, he scarcely inherits a single point of the longhorned breed; his horns excepted. When I saw him in 1784, then six years old, and somewhat below his usual condition, though by no means low in flesh, he was of this description.

His head, chap, and neck, remarkably fine and clean. His chest extraordinarily deep; his brisket down to his knees. His chine thin; and rising above the shoulder points; leaving a hollow on each side, behind them. His loin, of course, narrow at the chine; but remarkably wide at the hips; which protuberate in a singular manner. His quarters long, in reality; but, in appearance, short; occasioned by a singular formation of the rump. At first sight, it appears as if the tail, which stands forward, had been severed from the vertebrae, by the chop of a cleaver, one of the vertebrae extracted, and the tail forced up to make good the joint: an appearance, which, on examining, is occasioned by some remarkable wreaths of fat, formed round the setting on of the tail: a circumstance, which, in a picture, would be deemed a deformity; but, as a point, is in the highest estimation. The roundbones snug; but the thighs rather full, and remarkably let down. The legs short and their bone fine. The carcase, throughout (the chine excepted), large, roomy, deep, and well spread.

His horns apart, he had every point of a Holderness or a Teeswater bull. Could his horns have been changed, he would have passed, in Yorkshire, as an ordinary bull of either of these breeds. His two ends would have been thought tolerably good; but his middle very deficient. And I am of opinion, that had he been put to cows of these breeds, his stock would have been of a moderate quality. But being put to cows, deficient where he was full (the lower part of the thigh excepted), and full where he was deficient, he has raised the longhorned breed to a degree of

perfection which, without so extraordinary a prodigy, they never might have reached.

No wonder that a form so uncommon should strike the improvers of this breed of stock; or that a carcase they had been so long striving in vain to produce, should be rated at a high price. His owner, however, happened to be among the first of his admirers, and could never be induced to part from him, even for a season; except to Mr. Princep; who had him two seasons, at the extraordinary price of eighty guineas a season. A price at which no other bull has yet been let.

This extraordinary animal is now (1789) eleven years old, and firm in his constitution; but so lame, in his hind quarters, as to render him at present, and during the last season, entirely useless.

His owner, however, has less to regret, as he is in possession of many valuable females of his produce; and of one male, now three years old, by the name of Garrick.

This bull was out of a cow got by a bull of Mr. Bakewell, called the Hampshire bull.

Thus, though we find Mr. Fowler, at present, in possession of the lead, he has evidently obtained it through the assistance of Mr. Bakewell's stock. But whether he has gained the ascendancy by accident, merely, or whether he had the better basis to build upon, may be a moot point difficult to determine.

Mr. Fowler's cows (about five and twenty in number) are many of them an extraordinary mould; especially in the fineness of the foreend, and the width and fatness of the hind quarters. A daughter and sister of Shakespear, being got on his own dam, is among the first of his herd: another evidence of the good effect of breeding from the same family. Mr. Fowler conducts his business on the old principle of selling, not on the modern way of letting, his bulls. Such heifers, too, as his own dairy does not require, he sells, and at high prices. Mr. Coke of Norfolk has had all the cow calves he could spare, during the last three or four years, at, I understand, ten guineas each; taking them while young. Mr. Fowler has now (October 1789) ten bull calves (all, I believe, by Garrick), for which, it is said, he has refused five hundred guineas.

Mr. Princep's cows, of his own breed, have been mentioned as being of a very fine quality: nevertheless, his present herd wears evident marks of improvement. Every cow and heifer of the Shakespear blood is distinguishable at sight;—by the extreme fineness of the foreend,—the width of the hips,—and the formation of the rump; an impression which they have received with singular exactness.

Mr. Princep has two valuable bulls, by Shakespear: one of them out of the celebrated Bright.

Beside the three herds that are here particularised, there are many others, in the midland district, that are entitled to great attention; but which, for various reasons, I think may, with propriety, be omitted in this register. Therefore what remains to be added to the foregoing account of the present state of the breed, is a general description of its higher class of individuals.

The foreend long; but light, to a degree of elegance. The neck thin; the chap clean; the head fine, but long and tapering. A thick short head, with a snub nose, and a hollow face—provincially a Dutch head—is condemned, here, as a most hateful point.

The eye large, bright, and prominent.

The horns vary with the sex, &c. Those of bulls are comparatively short—from fifteen inches to two feet:—those of the few oxen that have been reared of this breed are extremely large:—two and a half to three and a half feet long:—those of the cows, nearly as long, but much finer; tapering to delicately fine points. Most of them hang downward, by the side of the cheeks, and, if well turned, as many of the cows are, shoot forward at the points. Too frequently, however, the double bend does not take place; the horns continuing to shoot downward, until they would reach the ground, or point inward until they would gag the mouth which supports them, were not the points from time to time removed: and, in some individuals, while one horn is pointing to the ground, or winding under the jaw so as to prevent its opening, the other is shooting away from the head, or taking some other awkward direction: thus tending to disfigure and destroy the animal which nature ordained them to ornament and defend.

The shoulders remarkably thin and fine, as to bone, but thickly covered with flesh; not the smallest protuberance of bone discernible.

The girt small, comparatively with the shorthorned and middlehorned breeds.

The chine remarkably full, when fat; but hollow, when low in condition. This is considered by accurate judges, as a criterion of good flesh; as the large, hard, ligatures, which in some individuals, when low in condition, we see tightly stretched along the chine, from the setting on of the neck to the fore part of the loins, is a mark of the flesh being of a bad quality.

The loin broad, and the hips remarkably wide, and protuberant. The protuberance of the bones of the hips, is a point at present in the first fashion; but is always, I observe, mentioned in the language of enthusiasm, not of reason. A wide loin, with the hips protuberating in fat, is indisputably a most desirable thing. But what use, or even ornament, two knobs of bone can produce, is not to me evident. In some individuals they have to me an artificial appearance; as if the loin were a lid, and the hips handles to remove it. I can admire a full hip, and conceive its utility; but I am clearly of opinion, that there are many points of a bullock better entitled to the breeder's attention, than a protuberant one; yet, it is more than probable, that, in the improvement both of this and the shorthorned breed, points of some consequence have been sacrificed to this idol.

The quarters long and level; the nache of a middle width; with the tail set on variously, even in individuals of the highest repute.

The roundbones small; but the thighs in general fleshy; tapering however, when in the best form, toward the gam-brels.

The legs small and clean, but comparatively long. The feet in general neat, and of the middle size.

The carcase as nearly a cylinder as the natural form of this animal will allow. The ribs standing out full from the spine; receiving the entrails within them. The belly of course appears small. The smallness of the belly is held out as a superior excellency. The viscera being lodged within the ribs is certainly such. But I cannot believe that a paucity of intestines is a valuable property of cattle: intestines are to them what roots are to trees. The ideas of offal, and largeness of bone, have, perhaps, in more points than one, led the improvers away from perfection. This, however, by the way.

The flesh, of the superior class I am describing, seldom fails of being of the first quality.

The hide of a middle thickness.

The colour is various: the brindle, the finchback, and the pye, are common: the lighter they are, the better they seem to be in esteem. This colour, however, appears to be merely a matter of fashion. Nevertheless, it strikes me that a light colour of cattle is advantageous to the grazier. It is a fact, in the nature of vision, that white objects appear to the eye larger, than black ones of the same size; and a light-coloured bullock, no doubt, appears larger in a market, than a darker-coloured one, of the same weight.

It may be remarked, in this place, that the six cows which formed the basis of Mr. Webster's breed, were red, and it is observable that some of Mr. Fowler's best cows are of that colour.

The fattening quality of this improved breed, in a state of maturity, is indisputably good.

As graziers' stock, they undoubtedly rank high.

As dairy stock, however, their merit is less evident: dairy-women here, and elsewhere, bear witness against them: nevertheless, the advocates for the breed assert their eligibility in this character: some, indeed, go so far as to say, that a cow which is profitable to the grazier is so to the dairyman: a position that might be contradicted by a thousand evidences.

Nevertheless, it appears to me probable, that a cow may be so constituted, as to convert her aliment into milk, while milk is continued to be drawn from her, and, when the draught is stopt, but not till then, to convert the same current of chyle into fat: a versatility of constitution, however, which I believe, does not belong to the breed under notice; whose propensity to fatness appears to be too great, to permit their lactescent powers to preserve the ascendancy long enough for the purposes of the dairyman.

As beasts of draft, the carcase of the longhorned breed, viewed generally, renders them unfit: nevertheless, the carcase of some of the best of the variety under notice, is sufficiently powerful for the purpose of draft; while their natural

natural activity, and cleanness of limbs, are very favourable to this purpose.

But the enormous size of the horns, of the oxen of this variety, would invalidate all their qualifications, were they greater than they really are. If they happen to take a convenient form, they may be dispensed with; but standing out awkwardly, as they frequently do, they become an insuperable objection.

A method of preventing their growth, or even of checking their exuberance, would be a most valuable discovery; to those, especially, who are in possession of the breed, and wish to make them useful as beasts of draft.

From this description of the improved breed of cattle of the Midland counties, it appears very evidently, that the principles of improvement, laid down afore-going, have, to this species of livestock, been judiciously applied. The utility of form has been strictly attended to: the bone and other offal small; and the forend light; while the chine, the loin, the rump, and the ribs are heavily loaded; and with flesh of the finest quality.

The males and females require to be treated of separately, in breeding.

Viewing the district at large, its economy with regard to bulls, is the same as that of other places. Dairymen in general, use their own bulls, generally of their own rearing; and smaller cowkeepers employ those of their neighbours. But dairymen who pay a closer attention to their stock, purchase their bulls, or hire them by the season, of bull-breeders; who rear, perhaps, five to ten bulls yearly; the superior breeders, for letting; the inferior, for sale.

The practice of letting this species of male stock, probably originated in this district; and in the practice of Mr. Bakewell; about twenty-five years ago.

In the spring, previously to the season of business, the breeders have their private shows; and beside these, as has been intimated afore-going, there are public shows; more, however, for the purpose of sale, than of letting.

The prices given for bulls, by purchase, run from five to a hundred pounds; by the season, from ten to fifty or sixty; by the cow, from half a crown to five guineas.

The let bulls are sent out in April or beginning of May; being generally led in halters; or driven singly; and are returned at the end of the season—generally in August, in the same manner.

With respect to the age at which bulls do business, as it is technically termed here—the practice of this district differs from that of most others; where from two to four years old, namely three seasons, is the ordinary period of employment. But, here, they are pretty commonly allowed to leap while yearlings; and, if good stock-getters, are kept on so long as they will do business; perhaps till they are ten or twelve years old. If they grow vicious, they are kept wholly in the house; if they throw gates or break pasture, they are humbled by a bull chain, fastened ingeniously to the nostrils.

It is observable, in this place, that the bulls of this improved breed are not unfrequently even while youthful, deficient in vigour:—the hired bulls being sometimes returned prematurely on this account.

This might be laid hold of as an argument against the practice of breeding in-and-in. It is, however, more probably owing to a different cause.

A handsome bull,—a bull nearly perfect in all his points, is most difficult to breed: yet the breeder's object is to render him, to the eye at least, as near perfection as may be. He is, therefore, made up for the show, by high keep; as well to evince his propensity to fatness, as to hide his defects; thereby showing him off to the best advantage: the consequence of which is, being taken from this high keep, and lowered, at once, to a common cow pasture, he flags.

Hence, it is become a practice of judicious breeders, when their bulls are let early enough, to lower them down, by degrees, to ordinary keep, previous to the season of employment.

There is only one instance, I believe, of cows being kept solely for the purpose of breeding: the dairy being here, as every where else, a joint attention.

Such as are not employed in the rearing of calves, ought certainly, in common good management, to be made to pay for their maintenance by milking or working: the last, a use to which Mr. Bakewell alone, perhaps, has put them.

One circumstance in the management of breeding cows, practised by leading breeders at least, is noticeable. In the

practice of less spirited and less judicious breeders, a cow or heifer, if she happen to miss the bull, is proscribed, let her form and blood be what they may; and, as soon as her milk is obtained, is condemned, even for the first offence.

This, when dairying alone is the object of cowkeeping, is undoubtedly judicious; but, when breeding is a principal or even a joint object, as it is in the practice of most dairymen, such a conduct may be highly blameable. For though it may be easier to breed handsome good cows, than bulls of that description; yet, when we consider how much of the success of breeding depends on the female, it is evidently a want of common policy, to cut off a valuable cow, for one miscarriage.

If she do not breed this season, let her maintain herself by working, until the next. Mares are kept, year after year, without breeding. And if mares are found nearly equal to geldings, in work; why should not cows be nearly equal to oxen, in the same intention?

The rearing of cattle is here confined to bulls and heifers, for breeding, and the dairy: there is not, in ordinary practice, a steer reared in the district; excepting some few of late years, for the purpose of draft.

The method of rearing, here, differs little from that of other districts; except in the rearing of bull calves, and sometimes high-bred heifers, by suffering them to remain at the teat, until they be six, nine, or perhaps twelve months old; letting them run, either with their dams; or, more frequently, especially where the dairy is an object, with less valuable cows or heifers, bought in for the purpose; and, when the intention is fulfilled, sold, or fatted: each cow being generally allowed one male calf, or two females.

The effect of this practice is a quick growth; and, perhaps, like rearing vegetables in a rich soil, the practice may assist in meliorating the constitution, and enlarging the frame. Be this as it may, the growth of calves, reared in this way, is strikingly rapid.

The best method of the dairymen is this:—The calves suck a week or a fortnight, according to their strength (a good rule): new milk in the pail, a few meals:—next, new milk and skim milk mixt, a few meals more: then, skim milk alone; or porridge, made with milk, water, ground oats, &c. and sometimes oilcake,—until cheese-making commence: after which, whey porridge, or sweet whey, in the field; being careful to house them, in the night, until warm weather be confirmed.

Turneps are not thought of as a food for calves: nor, in the ordinary practice of the district, is either corn, cake, or linseed in use; milk, whey, hay, and grass, being the sole food of rearing calves, until autumn, when turneps are usually given.

The time of rearing extends, in this district, through the winter months; but is confined, in a great degree, between the beginning of December and the latter end of March.

In the treatment of young stock, I find little in the practice of this district, that requires particular notice.

The bulls, in the common practice of dairymen, are suffered to ride while yearling; namely, at fifteen to eighteen months old; and the heifers to take them, while two years old; bringing them into the dairy at three years old: generally keeping them from the bull until late in the summer,—as the latter end of July, or the beginning of August;—it being a pretty general opinion, that heifers should come in at grass: beside, by this practice, one bull serves both the dairy cows and the heifers. I have known a dairy of twenty or thirty cows, and ten or twelve heifers, served by a calf;—a yearling bull.

In the practice of superior breeders, heifers are sometimes kept from the bull until they be three years old; bringing them in at four: especially in that of their enterprising leader; in whose superior practice, maiden heifers, as well as dry and barren cows, are occasionally enured to harness: a laudable example, that might be profitably followed by every other breeder of cattle.

In the choice of cows, dairy farmers are guided by criteria different from those which have been enumerated as the favourite points of graziers and modern breeders, for which, *see* DAIRY.

In Mr. Marshall's Rural Economy of Yorkshire, he speaks of cattle in that county, and says, "Within the memory of a person now living: namely about seventy years ago; the ancient breed of black cattle, which probably once prevailed

ailed throughout England, and whose name is still very improperly used in speaking of cattle in general, were the only breed of cattle in this district. By description, they appear to have resembled the present breed of the Lowlands of Scotland; mostly all black; but some with white faces: mostly horned; but some of them "humbled;" that is hornless.

To these succeeded a black and white breed; probably a variety of the original species. But still the red cow's milk was considered as medicinal; and many inveterate disorders were no doubt cured with it, that is to say by a perseverance in milk-diet.

The black mottles, probably a transient sort, were succeeded by the long-horned or "Craven breed;" the probable, and, I believe, undoubted origin of the present celebrated breed of the Midland counties.

But in a country where the business of aration was carried on principally by oxen, this breed was found extremely inconvenient. Horns a yard long were not only troublesome but dangerous in yoke; especially in the narrow roads and hollow ways with which the district formerly abounded. Accidents were frequently happening to them; by getting their horns entangled in the hedge or the back; sometimes breaking off their horns; but more frequently breaking their necks.

This was a sufficient inducement for adopting the short-horned or "Holdernefs breed;" probably of Dutch extraction. This change took place some forty or fifty years ago: and the short-horned breed still prevails; though it has undergone several alterations since its first introduction.

The first variety of this species of cattle which I can recollect, was a thick, large-boned, coarse clumsy animal: remarkably large behind, with thick gummy thighs. Always fleshy, but never fat; the flesh being of a bad quality. This, however, was not the worst: the monstrous size of the buttocks of the calf was frequently fatal to the cow. Numbers of cows were annually lost in calving. These monsters were stigmatized with the epithet Dutch-buttocked. This was probably the worst breed the Vale ever knew.

The unprofitableness of the Dutch breed being evident, men of discernment began to set out about improving it. In the course of the last twenty years the bone has been lowered, the hind-quarters reduced, and the flesh and fattening quality very much improved; not by foreign admixtures and unnatural crossings, but by choosing the cleanest and best-fleshed bulls and heifers from among their own or their neighbours stock.

It is very observable, however, that in effecting this improvement, the horn has been considerably lengthened; the present prevailing breed appearing as if it were a cross between the old short horizontal horn (provincially, buckle-horns) and the middle elevated horn of Herefordshire and Suffex: not, perhaps, from either of these breeds having been employed in the improvement, but merely from the circumstance of a fine horn, namely, a clean, small, sharp, horn - having been fashionable for the last twenty years.

This shews how much the appearance as well as the nature or constitution, of a given breed of stock may be altered and improved, without calling in the assistance of alien breeds. Even the Dutch bullocks were probably bred in England.

The Holdernefs breed, on their first introduction into the Vale, were said to be thin-quartered, too light behind, and too coarse before; large shoulders, coarse necks, and deep dewlaps. This form being found disadvantageous to the butcher, encreasing the quantity of the coarser parts, and reducing the weight of the prime pieces, the breeder endeavoured to enlarge the hind-quarters; and had he stopped when he had got to the happy medium, he would have wrought a good work. But the fashion was set; cloddy bullocks were in estimation; and their evil qualities were overlooked until they were rendered too obvious, and the consequences above mentioned had taken place.

The form and size of the present breed of the Vale may be seen in the following dimensions of a working ox rising five years old; above par as to form, but somewhat beneath it in point of size.

Height at the withers, four feet eleven inches.

— of the brisket from the ground, twenty inches.

Smallest girt, seven feet four inches.

Largest girt, eight feet five inches.

Greatest width at the shoulder, twenty-two and a half inches.

— at the huckle, twenty-three and a half inches.

Greatest width at the round-bone, twenty-one inches.

Length from forehead to nache, eight feet five inches.

— the centre of the shoulder knob to the centre of the huckle, four feet one inch.

— the centre of the huckle to the extremity of the nache, twenty-two inches.

Length of the horns, fourteen inches.

Width of the horns at the points twenty-two inches.

The eye full and quick.

The head and neck clean.

The bone somewhat large.

The chine and buttocks full.

The flesh soft and mellow to the hand.

The colour blood-red, marked with white.

But a variety new to the Vale is now creeping into it: the Tees-water breed; a variety of the short-horned species. This variety is established on the banks of the Tees, at the head of the Vale of York, and is held out as the true Yorkshire short-horned breed. Be this as it may, much attention has been bestowed on its establishment; and it appears to be at present a most valuable breed of cattle: valuable, I mean, to the grazier and butcher: the bone, head, and neck fine; the chine full; the loin broad; the carcase throughout large and well-fashioned; and the flesh and fattening quality equal, or perhaps superior to those of the present breed of the Vale; which, however, appear to be more active, more athletic, and fitter for the yoke or harness.

In forming that variety, a horn very different from that which is prevalent in the Vale has been produced. The buckle-horn is in this case, as in the other, somewhat lengthened; but the fashionable horn on the banks of the Tees is a clubbed down-hanging horn, as if in forming it, a dash of Craven blood had been thrown in: and it may be a moot point whether the horns of the two breeds, now particularly under notice, may have been produced by fashion alone; or whether the Tees-water horn may not have been altered from the original short horn, by a slight intermixture of the Craven breed; and whether the Holdernefs breed from which the Vale cattle have indisputably originated, may not have had a similar admixture of the middle-horned blood.

I wish to trace the origin and progress of the different breeds of cattle in the island; but I find it will be a difficult task to do it with strict accuracy.

The horn is the best criterion for distinguishing the different species, if the term be applicable, of cattle. It is a permanent specific character. The colour, though not altogether accidental, is changeable; and neither the form nor the flesh are permanently characteristic of any particular species. Good form and good flesh may be found in every species; though they are by no means equally prevalent nor equally excellent in all. But a horn six inches long was never yet produced by the Craven breed; nor one a yard long by the Holdernefs breed. And the middle-horned breed of Herefordshire, Suffex, and other parts of the island, appears to be as distinct a species as either of the former.

These are my only reasons for being so minutely descriptive of the horns of cattle. I am not a bigot to horns of any shape or length. I would as soon judge of a man's heart by the length of his fingers, as of the value of a bullock by the length of his horns.

If his flesh be good and well laid on, and his offal be proportionably small; if he thrive well, fat kindly at an early age, or work to a late one if required; I would much rather have him entirely without horns, than with any which enthusiasm can point out.

The doctrine of horns has long appeared to me as a species of superstition among farmers, and as a craft convenient to leading-breeders, in their respective systems.

But lest I should have cause to repent of my rashness in speaking thus irreverently of horns, I will here allow them all the merit which, in my opinion, truth entitles them to.

The horn has been mentioned as a permanent specific character of cattle. Hence in varieties it may have its use as a criterion. Thus supposing a male and female of superior form and flesh, and with horns resembling each other as nearly as the horns of male and females of the same variety naturally do, no matter whether short or long, sharp or clubbed, rising or falling; and supposing a variety to be established from this parentage, it is highly probable that the horns of the parents would continue for a while to be characteristic of the true breed, and might by inferior judges be depended upon, in some degree, as a criterion.

But it is indisputable that horns remain the same, while the flesh and fattening quality change; and every man of superior judgment will depend more upon the form and handle of the carcase, than upon the length and turn of the horn. For it is a notorious fact, that the individuals of a given variety may have exactly the same horns, without having exactly either the same fashion or the same flesh.

If there be any criterion or point of a beast which may be universally depended upon as a guide to the grazier, it is the EYE, not the horn. The eye is a mirror in which the health and habit of the animal at least may be seen with a degree of certainty."

The same author, in his *Economy of Gloucestershire*, says, the Herefordshire breed of cattle,—taking it all in all,—may, without risque, I believe, be deemed the first breed of cattle in this island.

This superior variety of the middle-horned breed has been noticed: and its oxen minutely described. In general appearance, the Herefordshire cattle resemble very much those of Sussex, except in their superior size: and still more nearly the present breed of the Vale of Pickering: notwithstanding these several districts are separated near two hundred miles every way from each other; with other breeds of cattle intervening. Their frame is altogether athletic, with the limbs, in most cases, sufficiently clean, for the purpose of travelling. The form of many of them, as beasts of draught, is nearly complete.

Besides their superiority as beasts of draught;—and their being eligible as dairy stock (being in this respect similar to those of Gloucestershire):—the females at least, fat kindly at an early age; the strongest proof of their excellency as fattening cattle. I have seen three year-old heifers of this breed to use a familiar phrase—"as fat as mud": much fatter than any heifers of that age, I have seen of any other breed;—the spayed heifers of Norfolk excepted.

Viewing the Herefordshire breed of cattle in this light, which I believe to be a true one; how unfortunate, for the rural affairs of these kingdoms, has been the choice of the spirited breeders of the Midland counties! The superior varieties of the Midland breed, beside being beautiful in their form, are indisputably well adapted to the grazier, when kept to a proper age: and other varieties are well enough adapted to the dairymen: but for the arable farmer as beasts of draught, they are far inferior to many other breeds: which, with a small share of the attention and expence that have been bestowed on the longhorned breed, might, I am fully persuaded, have been rendered equally or still more profitable, as milking cattle and grazing stock; and, at the same time, have been fit for the purpose of draught:—a use, for which, not the horns only, but their general frame unfits them. I have seen them no where, in common use as beasts of draught.

Nevertheless, we see the long-horned cattle, not only in full possession of the more central parts of the island, but overrunning the marginal districts in every direction. A circumstance, which to my mind appears to be of serious importance. The working of cattle is in the way of being, perhaps, irretrievably cut off; and whenever the spirit of breeding shall flag, and the art fall into neglect, the intire country will be burthened with a breed of cattle, naturally, the worst, perhaps, it ever knew. The long-horned cattle in a state of neglect, might, in figurative language, be called creatures without carcase: all horns and hide. With every assistance which genius and spirit can give them, they are barely, if at all, superior, even as grazing stock, to other breeds, which have remained in a state of comparative neglect.

These observations result not from an antipathy to this breed of cattle; nor from a want of respect for its present distinguished breeders. Nor did they, I trust, originate in a want of knowledge of the breed itself. There is no other breed of which I have had so much experience. If, however, after fifteen years acquaintance, I still remain a stranger to its merits, and have in consequence formed a wrong judgment, I wish and ask to be set right.

I am the more desirous to form an accurate judgment of the longhorned breed of cattle, as I hope to have, very soon, an opportunity of digesting my ideas respecting it, and of pursuing its excellencies as far as facts will enable me. There are undoubtedly, some varieties of it raised to an almost incredible height. And lest, infatuated with the fairness of their form I may, in their praise, be led beyond truth, I have, here, compared their general nature

with that of a breed, which I consider as the first the island affords, that, by having a standard to refer to, I may be the better enabled to regulate my judgment.

In Herefordshire, working oxen are the principal object of breeding. Great numbers of cattle are here in use, as beasts of draught. Half the plough teams appear to be of oxen; which are likewise, often used in carriages: The ox cart—provincially "wain"—is here a common implement. They are still, in general, worked double, in yoke: even in the deer-forested parts of the district; with however, some few exceptions.

One circumstance in the management of cattle, in this county, is to me a matter of some surprise. The spaying of female calves is not here a practice. This circumstance is the more remarkable, as the excellency of spayed heifers, not only as beasts of draught, but as fattening cattle, is indisputable: and still more extraordinary, as, Herefordshire not being a dairy country, numbers of female calves must every year be fatted for the butcher. How much more eligible management it might be to castrate, indiscriminately, the handsomest and cleanest, of such males or females, not wanted for the purpose of breeding, as drop in the rearing season.

The oxen are bred chiefly in the north-western quarter of the county; but more or less, in every other: except the Ryeland quarters. They are moderately worked until they be five or six years old; at which age they are sold mostly in good condition, but some times out of the yoke, to the graziers; principally, I believe, of Buckinghamshire, Wiltshire, Warwickshire, Gloucestershire, and the neighbouring counties.

Mr. Marshall says, that "At Hereford fair the 20 October (1786) there were about a thousand head of cattle: chiefly of this breed, with a few Welch cattle. A large proportion of them were grown oxen, full of flesh, and sold, or worth at the selling prices of the day, from twelve to seventeen pounds an ox. The most valuable collection of cattle I have met with out of Smithfield: and by much the finest show I have any where seen. Had they been arranged in a proper fairstead, instead of being huddled together, as they were in the streets of the town, they would have formed a still finer exhibition. The impropriety of continuing to shew cattle for sale in the streets of towns is evident at Hereford; whose streets having been newly paved in the London manner, the town's people to save their windows, and to preserve a passage to their houses, very prudently run a rope on the outside of the foot pavement; by which means the cattle are either crowded together in the middle of the street creating a state of confusion, I have no where else observed; or, if headed against the rope, stand with their fore feet in the kennel! An awkwardness which needs not to be described.

Mr. Marshall, relative to Gloucestershire, says, "Cattle are the natural inhabitants of a vale country; and in this Vale we find every description of them abound: cows, rearing stock, fattening cattle; and each of these of various species, or breeds.

Formerly, and perhaps not long ago, one breed of cattle might be said to possess the Vale; a breed which still predominates in some parts of it. It is known by the name of the Gloucester breed; and has, I understand, been common to the district time immemorial. Welch cattle, no doubt, may have long been brought into the district, as fattening cattle; and of late years some considerable numbers of Herefordshire oxen have been fatted in it. But still the cows and rearing cattle were of the Gloucestershire breed.

Of still later date, however, an alien breed of cows have been introduced: the long-horned breed of Staffordshire and the other Midland counties, by the name or the "north-country sort;" a breed, that, in a few years, has made rapid advances, and is likely to dispossess, in no great length of time, the naturalized species. In 1783, dairies were mostly of the Gloucestershire breed: in some a mixture of the longhorned sort was observable; and, in the lower Vale, a few dairies were mostly of that breed. Now few dairies are left without admixture; and, even in the upper Vale, are some entire dairies of the long-horned breed. In general, however, they are an unsightly mixture of the two species; with, not unfrequently, a third sort, a mongrel kind, reared from an awkward cross between them. In the fairs and markets of the Vale, scarcely any other than the north-country sort and this mule breed are to be seen.

Of the long-horned cattle of the Midland counties I mean to speak fully at a future time. Welch cattle are extremely various: every province of the principality seems to send out a separate breed. They are invariably of the middle-horned species; but in regard to size they vary, in regular gradation, from the largest ox to the lowest Welch runt. The Gloucestershire, therefore, is the only breed which requires to be described in this place.

The Gloucestershire breed of cattle is a variety of the middle-horned species. In size, it forms a mean between the Norfolk and the Herefordshire breeds. The head mostly small, neck long, shoulder fine, and all of them generally clean. The carcass mostly long, with the ribs full, and the barrel large in proportion to the chest and hind-quarters. The huckle of due width; but the nache frequently narrow. The bone, in general fine; the hide thin and the hair short. The characteristic colour dark red, provincially brown, with the face and neck inclining to black, and with an irregular line of white along the back. The horns fine and rather long; but, in some individuals, placed awkwardly high on the forehead, and near at the roots: in others, however, they stand low and wide, winding with a double bend, in the middle-horned manner.

The principal objections of the Gloucestershire breed of cattle are, a deficiency in the chine, and too great length of leg, giving the individuals of this description an awkward uncouth appearance.

But no wonder: the breed has not had a fair chance of excelling. I have heard of only one man, within memory, who ever paid any especial attention to it; and this one man, by some election strife (a curse in every county) was driven out of the Vale about seven years ago; so that at present it may be said to lie in a state of neglect. Nevertheless, it still contains individuals which are unobjectionable, particularly the remains of the Boddington breed; and, with a little attention, might, in my opinion, be rendered a very valuable breed of cattle.

For dairy cows, I have not, in my own judgment, seen a better form. It is argued, however, that the north-country cows, being hardier, stand the winter better in the straw-yard, and fat more kindly when they are dried off. It should be recollected, however, that Gloucestershire is a dairy country; and remember that it was the Gloucestershire breed that raised the Gloucestershire dairy to its greatest height. Beside, the breed has long been naturalized to the soil and situation, and certainly ought not to be supplanted, without some evident advantage; some clear gain in the outset; nor even then without mature deliberation, lest some unseen disadvantage should bring cause of repentance in future.

The three classes, enumerated at the head of this article, now require to be separately considered.

This being a dairy country, the procuring of cows, and the size of dairies, as well as the treatment, the application, and the disposal of cows, will require to be shewn separately under the article DAIRY.

Dairymen in general rear their own cows: some, however, purchase the whole, and others part, of their dairies.

The point of a milch cow which is here principally attended to, and which, no doubt, is the main object of attention, is a large thin-skinned bag: I have, however, heard a large tail spoken of, in the true tone of superflation.

The following are the dimensions of a cow of the Boddington breed. A genuine, and a fair specimen, as to form, but not as to size: the cows of that celebrated breed were, in general, considerably larger. As a milker she has had few equals; and, in my eyes, she is, or rather was, one of the handsomest and most desirable dairy cows I have yet seen. These dimensions were taken when she was five years old, off; she being then several months gone with her fourth calf.

Height at the withers four feet three inches.

—— of the fore dug twenty-one inches.

Smallest girt six feet and half an inch.

Greatest girt seven feet eleven inches.

Length from shoulder-knob to huckle four feet one inch.

—— from the huckle to the out of the nache twenty inches.

Width at the huckle twenty-two inches.

—— at the nache fourteen inches.

Length of the horn twelve inches.

The eye full and bright.

The ears remarkably large.

The head fine and chap clean.

The bosom deep, and the brisket broad, and projecting forward.

The shoulders thin with the points snug.

The thigh likewise thin, notwithstanding the great width at the nache.

The bag large and hanging backward, being leathery and loose to the bearing.

The teats of the middle size; gives much milk, and holds it long.

The tail large, the hide thin, and the bone remarkably fine.

The colour a dark brown, marked with white along the back and about the udder; with the legs, chap, and head, of a full, glossy, dark, chocolate colour.

The horns of a polished white, tipped with black.

The reasons given, by the dairymen of this district, for rearing their own cows are, "that they should soon be beggared if they had their cows to buy;" and "that they know what they breed, but do not know what they buy."

The latter has much the most reason in it; for, as they observe, if a heifer is not likely to turn out well, they sell her: on the contrary, if they went to market for their cows they must buy the outcasts of other breeders. Besides, they endeavour to breed from known good milkers; such as milk well, not only presently after calving, but will hold their milk, through the summer, and the latter months: whereas, in the market they are subject to chance, and the deceptions of drovers: the most they have to judge from is the size of the bag at the time of the purchase. In suitable situations, there can be little doubt of the propriety of every dairyman's rearing his own cows.

The place of purchase, in this district, is chiefly the market of Gloucester, held every Saturday; to which, in the spring, from fifty to a hundred cows, of different breeds, with calves by their sides, are brought, by dairymen and drovers; but principally long-horned cows, brought from a distance by the latter. In the Lady-day fair at Gloucester, there were not less than four hundred cows.

Mr. Marshall, in speaking of Cotswold Hills, says, "A good many cattle are kept in this district. Some cows are kept in the vallies; and on the skirts of the hills there are considerable dairies."

The species of cattle are the Gloucestershire, the long-horned, and a mongrel breed between those two.

In the higher townships, more particularly, perhaps, in the township of Northleach, cows are kept on "cow-downs" (old upland grass) in the day, and foddered in yards at nights, with weeds, rough grass, or other herbage, mown in the byeways and hedges. The craftsmen and farm labourers have each of them a cow: by this means they not only obtain a relief for their families, but acquire at the same time habits of industry. I mention this circumstance, as in all probability this was formerly the practice in most open upland townships throughout the kingdom.

The fattening of cattle is not the common practice of these hills: nevertheless they may boast of at least one good grazier. His practice is to buy in large Welch bullocks at Gloucester in autumn and winter. He gives them the run of the straw yard the first winter; and summers them on raygrass and clover leys, as companions to his fattening sheep, to eat off the bents of raygrass, and thereby not only give the sheep a freer better bite than they otherwise would have, but at the same time turns to a valuable purpose that which would otherwise (if not swept off with the scythe) remain an incumbrance to the surface. The ensuing winter, they are finished in stalls, with hay and secondary barley: a new, but an excellent practice.

His method of stall fattening merits particular notice. His fattening cattle are all tied up, some in single, some in double stalls. His reason for this practice is not altogether that of saving room; he is clearly of opinion that they do better, fat faster, than bullocks which are kept in loose stalls. His reasoning is fair: besides the indisputable advantage of their not being liable, in this case, to foul their meat and water; he holds out another which is not so obvious, but may nevertheless perhaps be equally true: cattle which are tied up are more cadish (tamer, less wild) than those which are kept in loose stalls. A loose bullock (some loose bullocks at least) when a stranger enters the shed, or any disturbance happens in it, will rise and fly into the yard for refuge; while a bullock which knows that he has not the power of flight will lie still and chew his cud. In the yards,

yards, loose bullocks are equally liable to disturbance; and quietness is no doubt essential to quick fattening.

Each bullock has two troughs; a small one for corn, a large one for hay, with a water trough, which runs the whole length of the shed, and is covered by a board; each bullock having a hole (large enough to admit the nose) to drink at. The water-trough (a hollow tree) forms, as it were, a top rail to the partition wall of the gangway. The others are beneath it, nearly level with the bed of the stall.

The corn is ground, and given to them, mixed among cut hay, two or three times a day; beginning with about half a peck, and encreasing to about a peck a day.

The method of feeding with hay, which in this instance is practised, does the practitioner infinite credit. He feeds his bullocks with hay as cart horses are usually fed with corn; giving it to them by handfuls at once: never more at a time than the two hands can grasp; continuing to feed them in this manner until they lie down, or until they refuse to eat. Thus they never have any hay to blow upon, (the great objection against tying up bullocks) even at night, they have not a mouthful left before them. The leading principle of this practice is, that fattening cattle should never be cloyed with food; should always eat with an appetite. In the morning they are fed with the worst of hay, (if any difference) for being then hungry, they eat it with an appetite. Thus the hay is eaten up clean, and the bullocks are preserved in a thriving habit, while the extraordinary expence, where a number of cattle are fatted at once, is inconsiderable. In this case it is proper to appropriate a man's time to their attendance, and he might as well be employed in feeding them by handfuls until they lie down, as in cloying them with armfuls, and idling the rest of their time away.

In Mr. Marshall's Rural Economy of Yorkshire, this experienced gentleman observes, that "Young cattle are, I believe, invariably, housed the first winter; generally loose, and are generally indulged with the best hay the farm will afford. Their summer pasture is such as convenience will allow them: mostly of a secondary nature. In the open-field state, the common was generally their summer pasture.

The second winter, oat straw is the common fodder of young cattle; generally tied by the neck in hovels, or under sheds. Their summer pasture, commons, woody wastes, rough grounds, or whatever best suits their owner's convenience.

At two years old the steers, provincially stots, are generally broke-in to the yoke; but are not, by good husbandmen, worked much at that age.

At two years old, also, the heifers, provincially whies, are generally put to the bull. This, however, is not an invariable practice. In the state of commonage they were frequently kept from the bull until they were three years old: now, in the state of inclosure and improvement, and at the present high rents, they are frequently suffered to take the bull when yearlings, bringing calves at two years old.

This is an interesting subject in the management of cattle. Farmers in every district differ in their opinions respecting it.

The arguments for bringing heifers in at two years old are, that they come sooner to profit; and that farmers cannot afford, at the present rate of rent, to let them run, unprofitably, until they be three years old.

On the other hand, the argument in favour of bringing them in at three years old is that, not being stunted in their growth, they make larger, finer cows than those which are suffered to bear calves at a more early age.

But I have not yet met with any man who even attempts to prove which of the two is, upon the whole, the more profitable practice.

The gardener seems to be well aware, that suffering a tree to bear fruit too early checks its growth; and there may be some analogy, in this respect between vegetables and animals. But even admitting this, if the cow receive no injury as to thriving, calving, milking, nor any other than that of being checked in point of size, the objection appears to me to fall. If, however, early production check not only the cow, but her progeny likewise, an objection no doubt will lie against it.

I have long been of opinion that it is, in general, the farmer's interest to let his heifers take the bull whenever nature prompts them. There is undoubtedly some pre-

sent profit arising from their coming in at an early age, and whether a middle-sized cow may not afterwards afford as much neat profit as one of larger stature, is certainly an undetermined point.

Much however depends upon keep. A starveling heifer will not take the bull at a year old. Nor ought any yearling heifer which has taken the bull, ever afterwards, to be stunted in keep. If she be ill kept while with calf, there will be danger at, or after, the time of her calving. If afterwards pinched, there will be danger of her not taking the bull the next year.

Hence we may infer, with a degree of safety, that the propriety, or impropriety, of bringing heifers into milk at two years old depends principally upon soil and situation.

On a good soil, and in a genial climate, in which heifers do not experience a check from the time they are dropped, they ought, I am clearly of opinion, to be permitted to take the bull whenever nature prompts them.

But in less genial situations, where lean ill-herbaged lands are to be pastured with young cattle, it appears to me equally evident, that heifers ought not, in strictness of management, to be suffered to come into milk before they be three years old.

The present dearth, arising beyond dispute from a real scarcity of cattle, appears to be a matter of serious import to the community. Had it not been for the immense influx of Irish cattle, which have, during the last three or four years, poured into this island, the grazing grounds could not have been fully stocked, nor the markets well supplied. There is not, generally speaking, any aged cattle left in this kingdom.

There can be only two reasons of this scarcity: either the consumption of beef must have lately increased, or the rearing of cattle must have diminished; or the effect must have been produced by the joint operation of the two causes.

I wish to bring the matter to a rational issue, and have endeavoured to collect evidences in the districts I have visited. This district affords two, which appear to be admissible.

Twenty or thirty years ago there was not, for the smaller markets of this district, a single beast killed (except upon some extraordinary occasion) during the winter, spring, or summer months. In autumn, particularly in the month of November, considerable numbers were butchered, to be salted and hung for winter provision; hung-beef being formerly a standing dish, not only in this, but in other districts. But the number which were then killed in autumn was small, compared with the much greater numbers that are at present butchered in the district; every market of which is now plentifully supplied with beef the year round; and this, notwithstanding considerable quantities are still hung in autumn. The market of Malton might well vie with the London markets. If only twice the quantity of beef be consumed in the district now, of what was consumed fifty years ago, the evidence is good.

Twenty or thirty years ago, great quantities of young cattle, bred in the common pastures, and in the rough grounds of the marshes, and other central parts of the Vale, were annually sent out of it. The number of lean oxen, too, which were sent out of the country was very considerable. Now, the Vale, perhaps, barely rears its own stock. A few young cattle may go out of it every year; but a number of Scotch and some Irish beasts, and generally more or fewer young cattle from the Tees-water quarter, are annually brought into it. A few lean oxen, (few in comparison with what formerly went out) and some barren cows; and a surplus of fat cattle driven to the ports of Whitby and Scarborough; may be said to be the only cattle which the Vale at present sends to market.

The causes of this decline are the increase of horses; the increase of tillage in the lower parts of the Vale; and the increase of the dairy upon its margins; an increase of grazing grounds in the richer parts; and, throughout, an increase in the consumption of beef.

This too may be fairly admitted as a circumstantial evidence, at least, of a growing scarcity of cattle at present in these kingdoms. I mean a scarcity comparative with the present consumption.

I shall, in their proper places, have other evidences, to produce. At present, therefore, I do not attempt any general conclusions.

Although grazing has of late years gained some footing in

in the Vale, it does not yet fall under the denomination of a grazing country. A detail of management must not therefore be expected: and the only incident of practice which has occurred to my notice, and which appears to be entitled to a place in this register, is the following: at once evidencing the propriety of finishing fattening cattle; and giving a favourable specimen of the Yorkshire breeds of cattle.

The subject of this incident is a cow which was bred and fattened in this neighbourhood. Her dam was of the improved breed of the Vale, with an admixture of the Craven or long-horned breed. Her sire a Tees-water bull of the first blood; being leaped at half-a guinea a cow; which, twelve years ago, was a very high price.

From the time of her being dropped she was remarked as a good thriver; she came in at three years old; had one cow-calf which was reared: and three bulls, all of which died before they were three weeks old! they being seized about that age with a numbness in their limbs; soon dying with jellied joints, and symptoms of a general mortification. Like most high-bred cows, she milked well for a few weeks after calving; but afterwards fell off her milk, and generally got to be good beef about Michaelmas.

After her last calf (in 1782) she was milked until August; when she was tolerable beef; worth, at the then low price of beef, about ten pounds. In autumn she had after-grass; in winter turneps, hay, and oat-sheaves (in the house), but no ground corn. In March 1783 she was sold for twenty pounds to return one guinea: consequently she paid more than six shillings a week for fattening.

Her dimensions, a few days before she was slaughtered, were these:

Height about four feet six inches (not accurately taken).

Smallest girt seven feet six inches.

Largest girt nine feet.

Length from shoulder-point to huckle four feet.

Length from huckle to the extremity of the nache, two feet two inches.

Width at the huckles from out to out, two feet two inches.

Her horns fine; of a whitish grey colour; sharp, somewhat resembling the Craven horn, but shorter; and turned upward at the points in the middle-horn manner: her head and neck small and clean; her legs short, and her bone throughout fine.

Her points as to fatness were not all of them full. Her kernel was small, and her shoulder bare; her fore-dug and flank not extraordinary; her chine and loin were well laid up; one dimple, but not regularly cloven; she was not what is called very fat upon: but her rib, her huckle, and her nache, were very good; and her twist remarkable; bulging out in an extraordinary manner.

She proved as follows: the quarters equal; exactly eighteen stones each; together seventy-two stones (fourteen pounds each); the tallow eight stones; the hide seven stones.

The weight is not remarkably great; but, that a small cow should lay it on in seven months is extraordinary.

Taking the dimensions of cattle, and describing their points with minuteness, is not merely a matter of curiosity. Nothing matures the judgment more speedily, nor gives a more adequate idea of the due proportions of the parts of a bullock. I never, however, understood that the admeasurement of cattle was reduced, any-where, to common practice, until lately. In the West of Yorkshire, I am told, the manufacturers, who kill their own beef, carry measuring tapes to market with them. The butcher by constant practice may be a match for the grazier with his eye alone: but it is certainly prudent in the clothier to take his measure with him also.

CAUTERY, a name given to a red hot iron, used by farriers to destroy fungous flesh, &c.

CAUTING-IRON, an iron with which farriers scar those parts of a horse that require burning.

CELLS, the small divisions in honey-combs, which geometers have observed, to be always regular hexagons.

CELLS, also denote the hollow places between the partitions in the pods, husks, and other seed-vessels of plants.

CENTAURY, the name of a weed abounding in arable lands, and generally called blue-bottle. See **BLUE-BOTTLE**.

CERES, a pagan deity, the inventor, or goddess of corn.

CERT-MONEY, a fine paid yearly by the residents of several manors to the lord thereof, and sometimes to the hundred, for the certain keeping of the leet.

CHAFF, the husks of corn that are separated by threshing and winnowing. See the articles **THRESHING** and **WINNOWING**.

CHAFF also signifies the rind of corn: thus, barley that has a thick rind is said to be thick chaffed.

CHAFF likewise implies straw, &c. cut small, and given to horses and other cattle, mixed with corn. See the article **CUTTING-BOX**.

CHALK, the English name of the white dry marl, with a dusky surface, found in hard masses.

Chalk is a lasting manure for such lands as it agrees with, which are particularly those of a cold sour nature, and stiff untractable clays. Pliny tells us, it was the custom of the ancient Britons to chalk their lands, by which they received a great and lasting improvement.

Farmers are apt not to distinguish sufficiently between the different kinds of chalk. The hard, dry, and firm, is much the fittest for burning into lime: but the fat unctuous chalk is by far the best to be used crude. This oily, viscous sort of chalk, is used in many places instead of marl, to which it is nearly allied, though of an inferior quality. It is even called marl in the isle of Wight, where their chalk is of a remarkably fat soapy nature; and they sometimes lay twenty-five waggon-loads of it upon one acre of ground. *Lisle's Husbandry*, vol. I. p. 66.

A correspondent of the editors of the *Museum Rusticum* strongly recommends chalk as a manure for clay-lands; but adds, it should be laid on rough, in large clods whereby the land will gradually receive the greater benefit by it. The salts in the air will penetrate, and crumble the clods; and the land on which the chalk is laid, will soon be brought into a state of fermentation, reduced and pulverised in a special manner, inasmuch, that afterwards, one ploughing will go as far towards bringing it into tilth as two before.

The quantity of chalk should be proportioned to the stubbornness of the soil; from fifteen to thirty tumbril loads on an acre.

The virtues of this manure are not exhausted unde, at least twenty years; nor are they much perceived till the third year; but for twelve or fourteen years the farmer will have reason to thank those who advised him to the step of chalking his clay lands: and happy is he who can afford to do it, provided he has a long lease; for lands not worth five shillings an acre have, by this means been, in a year or two, worth twenty. *Museum Rusticum*, vol. II. p. 305.

An old experienced farmer in the hundreds of Essex has, in the same work, given an excellent account of the benefits resulting from chalk laid on clay-lands, where, he justly observes, it insinuates itself into the small pores, and, raising a fermentation, exposes the clay more to the operations of the frosts, rain, sun, and air, by which means its too coherent particles are loosened, and it is reduced to a state of pulverization.

"We all know, adds this intelligent husbandman, that clay, when reduced, either by fermentation or attrition, into small and minute particles, is an excellent soil for affording plenty of nourishment to almost every kind of vegetable: it is therefore neutral to us, when possessed of a stiff clay, to go in search of means for producing these desirable effects.

"Chalk has been long allowed the palm in this respect: our ancestors, the ancient Britons, used it with great success; and the practice, as warranted by constant experience, has been handed down to the present age: is it not then a pity but a custom so profitable should not be made known to every part of his majesty's dominions?

"The chalk we use in Essex is mostly brought from Kent: it agrees well with our clays, and many fine fortunes have been made in this country by chalking farms: yet what may appear very strange, but is not less true, this same chalk, when laid on the clayey lands in Kent near the pits, does by no means answer the farmer's expectation.

"It has been a common saying among farmers, that chalk lasts only for a certain number of years, after which it leaves the land in a worse state than that in which it found it: but this is probably a mistake, owing to prejudice, negligence, or ignorance.

"When land has been chalked under a notion it cannot be hurt by cropping, they generally keep it in almost constant

constant tillage, and it pays well for the ploughings; but then the soil being, by such constant working, reduced to the pulverized state, the chalk escapes through the now-enlarged pores of the clay, and forms a crust under the loose stratum on the surface of the hard clay beneath, being washed down by the rains.

"The particles of clay being now deprived of their coatings of chalk, adhere one to the other, enlarge their surface, and become at length a coherent mass of stiff soil, like what it was before the land was chalked at all, not worse in quality, but nearly in the same state. Probably the chief reason which induces farmers to think the land impoverished by chalk, is, because they have, whilst the manure acted with its full vigour, being for many years used to great crops, forgetting, or perhaps never knowing, what crops the land yielded before any chalk was laid on it.

"A great deal of care is requisite in land after it is fresh chalked: if the large lumps are buried before they are strongly impregnated with the influences of the atmosphere, they will lie under ground undissolved, in a hard mass, for a great number of years, without benefitting the land in the least. For this reason, the farmer must not be in a hurry to bury his chalk: in fact, the longer it lies above ground the better, as it will then gradually be reduced into an impalpable powder, which, being mixed and incorporated with the clay, lessens the cohesion of its parts, enlarges its pores, and disposes it to yield that nourishment to vegetables, which, in its natural state, it is too retentive of.

"Clay is, by nature, possessed of a large stock of the food, whatever it be, which plants most delight in; but it is a stubborn soil, and will not, till compelled to it by some extraneous cause, give forth any of its riches. If it is pulverized by the instruments of husbandry which act by attrition, it becomes a proper bed for the reception of the roots of vegetables; but this pulverization is not to be effected without great expence of time and trouble: and it was the difficulty of this operation that induced our ancestors to search for some easier and shorter method for reducing the solid particles of clay; they effected it by means of fermentation, and this fermentation was raised, for the most part, by rotten horse-dung.

"When this manure became scarce, and difficult to be procured, it was necessary to have recourse to some other remedy to correct stiff soils. Chalk was found well adapted to the purpose: the use of it was after many years almost universally adopted, and experience has now, for many ages, justified the practice.

"It has been already observed, that chalk improves clay, not by adding to it any vegetative quality, but by mixing intimately with its substance, and lessening the cohesion of its parts.

"Let us, by way of illustration, suppose any given quantity of clay mixed and incorporated with a proper proportion of chalk, it will be found that the clay will possess a degree of lightness, which nature has denied it. Let this mixed earth be spread on a floor exposed to the weather in winter time; let it be frequently sprinkled with water, and be stirred about several times a day for some months: on an examination, it will then be found, that the chalk has subsided, and the clay become more compact than it was, but not so compact as it was before any chalk was mixed with it.

"The subsided chalk will form a complete stratum under the bed of clay.

"I have been the more particular in this account, because on the principle of subsidence I have founded a practice, which I have experienced to be profitable to myself, and therefore I think it not totally improper to be recommended to the notice of others.

"I had heard it long complained of, that the benefit resulting from chalk ceased after a course of years. I always thought, and indeed found, that the chalk subsided: this made me form an opinion that the chalk, even after it had subsided, might, in part at least, be retrieved; for the earth, which had been loosened to a certain depth, was, at the bottom of the loose mould, a hard compact body, which the chalk could not penetrate: here therefore it must, of course, rest in its subsidence, forming a thin coat on this hard body.

"About forty years ago I chalked the greater part of my farm in the manner prescribed by the custom of this country. For about fourteen years I enjoyed very good

crops; but at the end of that time they began to fail a little. As necessity is the mother of invention, I came to a resolution of trying an experiment on a field of twenty acres: accordingly, when the time came in which it was to receive a whole year's fallow for a crop of wheat, I caused the whole of it, soon after harvest, to be ploughed twice in a place, one plough following another in the same furrow.

"By these means I turned up an entire new earth, on which I immediately laid in the proportion of about three loads of chalk an acre, suffering it to lie rough all the winter.

"In the spring I gave it a second ploughing, and bestowed on it three more ploughings before Christmas, when I again left it rough for the winter.

"I must not, however, fail observing, that in all the ploughings after the first, the share went only the ordinary depth.

"In the second spring I raised as fine a mould as I could; by various operations, and sowed the field with barley, of which I had, at harvest, a crop to my entire satisfaction: my next crop was wheat, on which I sprinkled some clover-seed, which brought the land into the usual course of husbandry.

"The reason why my land begins to fail, in about fourteen years after chalking, is because I allow more ploughings to each crop than any of my neighbours, and these frequent stirrings cause the chalk, as I imagine, to subside sooner.

"My method answered so well, that I managed all my chalked land in the same manner with good success; and had, in consequence, a succession of good crops for ten years more.

"When the ten years were expired, I gave my land another trench-ploughing, which never failing to recover the chalk, I renew it at regular intervals, but lay no fresh chalk on it after the first trench-ploughing, being in all the rest content with what is already in the land.

"This method has stood the test of many years experience, and I have not the least reason to ascribe it to any thing peculiar in the quality of my soil: why, therefore, should it not succeed as well with others as it has done with me?

"Let me persuade such of your readers, as it may any ways suit, to make the experiment; it cannot be any great expence, and the result may turn out very greatly to their advantage.

"This doctrine of the subsidence of chalk is certainly founded on reason; the predominant natural soil will always precipitate that which is only adventitious, and in smaller quantity; for the same observation holds good when clay is laid on chalk.

"This subsidence may also be observed when clay is laid on sand, or sand on clay, as a manure; and might, perhaps, be extended to many other articles, so as to be deemed a general principle.

"Few know the benefits resulting on some occasions from deep ploughing: but in this, as well as in every other matter, discretion is to be the grand guide; and I would, by all means, advise the farmer to examine into the depth of his soil, by remarking what is thrown out of his ditches, or by the help of a borer. Let him judge by this, and he cannot well go astray.

"I must also give another caution to my honest brethren the farmers, which is, not to be in too great a hurry to crop a field after it has had a trench-ploughing; for the soil turned up from any considerable depth will be somewhat crude in its nature, till it is meliorated by the influences of the sun and air.

"I have generally found that one whole year's fallow is sufficient to effect this; but two winters and a summer I never knew to fail: it is chiefly frost which contributes to pulverize the chalk, and sweeten the soil; not but that it receives great benefit from the rain and sunshine, and particularly from snow, which is strongly impregnated with nitrous particles: all I mean to insinuate is, that one day's frost contributes more to sweeten a stiff, rough soil, than two days sunshine, rain, or snow.

"Let me in this place hazard a conjecture, which may, however, prove a fact: the reason why frost so much contributes to disunite the particles of clay, may be owing to its swelling the clods, and increasing their surface: the cavities occasioned by this swelling are filled with ice: when a thaw comes on, wherever the ice was, is a vacuum, and

the particles of which the clay is composed, being separated one from the other, crumble and fall in pieces; when they are in this state, and the land has been chalked, a single ploughing, well-timed, will cover their surfaces with the chalk-powder, and prevent them from speedily adhering one to the other.

"Your readers, who have been in countries where there are quarries of stone, must have observed, that, whilst in the quarry, it works better than after it has been exposed to the sun; for it hardens considerably after it has been out of the quarry some time. It is the same with chalk, which is apt to be hardened by lying a summer in the sun: for this reason, it is advisable, that the chalk intended for manure should be dug as soon as the winter sets in, and laid presently on the land. This method and time of chalking may occasion some increase in the expence; but the farmer will be paid for it in the end, and he will, by this management, soon reap the benefit of his labours.

"Let it not be imagined from any thing I have said here, that I trust solely to chalk for bringing me good crops: no, I always bestow, once in a course of three or four years, a reasonable coat of compost dung. I do not lay on the chalk with any intention that it should enrich the clay: my desire is, that it should bring it to the nature of a loam, as the dung will then take effect, and ensure the farmer a large crop, provided he guards himself against the depredations of weeds, which are too apt to have their seeds mixed with the dung made of long straw, and often grow faster than the corn, with which the corn should be cropped. Dung, when prudently applied, is, like many other things, of great use; but it is dangerous in the hands of an ignorant land-holder. The expence of procuring it in quantity will ruin him, and his crops will go near to be choaked by the encroaching weeds." *Museum Rusticum*, vol. III. p. 198.

This letter of the Essex farmer merits the particular attention of all those who have clayey, or very strong land, and are within a moderate distance of chalk, which is without doubt an excellent manure for such land. And it has been found that chalk, particularly the fat soapy kind, is likewise a very valuable manure for loams, and other lands much lighter than clays; and though in the lighter soils the chalk is apt to subside in a shorter time than it does upon clays, it is more easily recovered, and brought up again by ploughing a little deeper than ordinary, and at somewhat a smaller expence, than can be done when it subsides in a very strong land. Chalk therefore is a manure that appears to be of almost as general use as marle; of which indeed it seems to be a species, and not improperly called marle in the Isle of Wight.

"If chalk, says Mr. Lisle, be laid on clay, it will in time be lost, and the ground again return to its clay; and if the clay be laid on chalk, in time the clay will be lost, and the ground return again to its chalky substance. Many people think the land, on which the other is laid for a manure, being predominant, converts the manure into its own soil; but I conceive, in both cases, the chalk and clay is filtrated through the land on which it is laid, by time, and, being soluble by rains into small corpuscles, is washed through the land on which it is laid; for neither of these manures is able to unite, in its finest corpuscles, with the corpuscles of the land on which it is laid, so as to form so strict an union and texture with it as the land doth with itself, and is therefore liable to be borne downwards with rains, till no sign of it be left.

"It is said to be a common practice with many tenants in Hampshire, three or four years before they leave their farms, to chalk their meadows; by which means they will for three or four years sling out a great crop of grass, but that they will be much the worse for it ever after. This seems to carry some reason with it; for the chalk so mellow and opens the pores of the meadow, that it enables the land to exhaust its strength in all parts: for chalk does not carry so much fatness as dung does to the land it is laid on; but it disposes the land to bear such crops by its sweetness, and well disposing of, and correcting an ill quality the land had before: but still I do not see that this is any objection to the chalking of meadows, provided, whilst, by virtue of the chalk, they are bearing such burthens, you take care to refresh them with dung.

"Though chalk laid on meadows enables them to give a great crop for three or four years, and will then improve them, yet I take it to hold quite contrary in pasture; for the grass being thereby so much sweetened and increased,

keeps constantly so much the more stock, by which it is maintained always in the same vigour.

"It is probable, that chalk spread on sandy or wood-seary ground, laid up for pasture, may wash and sink in, and fill up the interstices, and thereby consolidate and mend the texture of such ground, and sweeten it; as it is a great alkali; and though in time most of the chalk may be washed downwards, so that the ground may loose its virtue, yet I do suppose the strength of the ground may still continue much better, by reason that such manure having made the sward of the grass come thicker and sweeter, the good pasturage on both accounts enlarges the quantity, and betters the quality of the dung the cattle leave on it, which, in return, maintains a better coat and surface to the ground: and as chalk fills up the vacuities of sandy, on wood-seary ground, so, on the contrary, it insinuates its particles into obstinate clayey and strong land, and divides it, by making, in a manner, a fissure, thereby hollowing and mellowing it; so that the two contrary extremes are cured by chalk.

"Chalk laid on hop-clover and rye-grass is a mighty sweetener and improver of these grasses, being laid upon it after harvest, at the beginning of the winter, or whensoever one can best tend it; the benefit will be soon conspicuous, especially if the ground be of a four clay, and apt to run to coarse grass." *Lisle's Husbandry*, vol. I. p. 66.

CHALKEY-Lands, are those which are impregnated with chalk, and from their white colour, are in some countries called white-lands.

The best produce of corn in chalky lands, is barley and wheat; oats will do well on them. Their natural produce for weeds is poppies, May-weed, &c. For grass-feed, saintfoin, trefoil, and, if rich, clover. The best manure for these lands, is rags, dung, folding of sheep, &c. These lands, if rain happens to fall on them just after sowing, before the corn gets up, will cause the earth to bind so hard, that the corn cannot get through it; but may be much helped by a light harrowing.

In Hertfordshire they manage these lands for corn in the same manner as they do their clay-lands. In Oxfordshire they commonly manure these lands with half-rotten dung, which, they say, prevents the binding of it, and some mix it with sand, which causes it to work short, especially if any thing dry; they commonly sow them there with wheat, mangel, and barley; only after wheat they sow pease or vetches: in sowing of which they are obliged particularly to take care to have fine weather, because of the land's binding; but if they have only two nights dry weather, they will do well enough. *Mortimer's Husbandry*, vol. I. p. 68.

Mr. Young, in his *Annals of Agriculture*, vol. ii. says, "that in Essex they use chalk as a manure. It is brought from Malden in Kent; a waggon load costs at the quay 10s. The method employed is this; the teams of five horses and a waggon and two men, go out about 12 at night, load at Malden, return, unload, bait, go again with the same waggon and horses, and return and unload, and all over by one o'clock at noon. This is, I think, the severest work I ever heard of: 24 miles with so heavy a load, twice to be loaded and twice unloaded by the same men, yet it is here common; they reckon that every load costs in the whole 20s. They lay from five to eight on an acre, either upon a clover lay while feeding, or on a summer-fallow; the effect exceeds any thing I have met with; a very thin dressing of it is seen immediately to an inch, like rotten dung, and lasts 20 years; 15 in great heart. I was shewn a field of wheat hanging on the side of a hill at the distance of half a mile, one part of which was evidently much inferior to the rest which was in general laid; that part was the only spot not chalked, the farmer not having time to finish the field; he was present and confirmed the account. The same farmer having chalked a field, brought some in a cart as they returned from the field, and spread it thinly on one spot in a piece of poor dry land; the whole was sown with turnips: during the whole season, from their coming up, that spot was to be seen at a great distance, and the roots were far larger than any where else.

"They think their lands will do nothing without chalk, insomuch, that the whole country will, in a few years have all been chalked. The soil on which it does such wonders is loam; they have very little clay, and no sand. On gravels the effect is but slight; it is good sound loam in which it answers like the richest dung.

It is a general opinion among them, that land which has once

once been chalked will not take it again, and this opinion seems to prevent the trial; they acknowledge, however, that mixed with earth and dung it is even then excellent. A very particular circumstance they have observed, is, that laying a slight dressing of chalk and earth, or dung, on a field never chalked, will take so much effect, that the same field will not then answer to chalk completely. Another remark they have also made, is, that the chalk presently gives the land a red colour; so that a part of a fallow that has been chalked will, from the tinge, be discernible at a distance.

"Upon my asking if they ever laid chalk upon meadows? I was informed they did not require it; besides, they supposed it would do harm, as they observe that it is a strong enemy to grazing; that is, to the ground covering itself with good grass. A field which before chalking will run of itself to a fine head of white clover, no longer does it after chalking: this is very remarkable, for one would suppose what is manure for corn would be so to grass.

"The chalk is not soft, but rather hard; the sharpest frosts leave very many lumps unbroken, so that they break them with pick-axes; and the hard bits that break to a clear white they say come from the bottom of the pit, and are esteemed better than the pieces which crumble between the fingers. I tried some pieces in vinegar and water, the effervescence with the former is pretty considerable though not near equal to what I have seen; but in water it falls very slowly, if at all.

"Some farmers have tried lime, and with great success, upon the soils proper for chalk; this is a fresh instance that the excellence of these manures much depends on the soil whereon they are laid; on good loams they take full effect, but on poor lands they find nothing to work on. About Enfield the same chalk does wonders, which at North-Mims has very little effect; the one is a rich loam, the other a poor gravel."

In the 4th vol. of the same work, Mr. Young gives an extract from a letter of Mr. Legrand's, of Guilton-House, near Sandwich, in Kent, wherein he says, "Chalk will improve, in some degree, any soil foreign to it. In a very high degree it will improve a sandy soil. I have paid in one year 50l. merely for the carriage, besides what I have fetched with my own teams. Quantity 40 loads per acre, at 40 bushels per load. It gives tenacity to a sandy soil, wonderfully improves it, and totally exterminates that pernicious weed the wild marygold, commonly called here the yellow bottle, so abundant in sandy soils. It is a received opinion, that chalk is slow in its operation; it is not always so. In the winter of the year 1783, the soil being hard frozen, and wheat upon the ground, I chalked over four acres, part of a field of 12; the produce 58 qrs. 5 bushels. The part chalked so greatly superior to the rest as to astonish every beholder.

"Through me (I say it not boastfully, I say it with pleasure) the dressing with chalk is widely extended in this neighbourhood.

"I have frequently tried chalk upon pasture land, but without the least success."

Mr. Young, in his *Experiments on Manures*, says, "The effect of chalk deserves notice. I have often remarked the wonderful degree to which some soils abound with the vitriolic acid; to lay on such large portions of a calcareous earth must naturalize this acid, and the salts thus produced are selenites; the crops have been the better for the chalk, resulting probably from that action on the acid; but not so much better as to give any reason to suppose the neutral body beneficial. Hence, therefore, upon these soils, chalk is only to be used as the means of improving that basis, whereon you in future intend to lay mucilaginous manures: how far this will answer does not appear; but I should observe, that the chalked portions were always drier, and more friable than the rest, which is a very great advantage."

CHANFRIN, the fore-part of a horse's head from one hand to the other.

CHANGE of crops, a very judicious part of husbandry, consisting in a change of different species of grain on the same soil.

Experience soon taught men, that even the most fruitful soil cannot constantly yield the same grain; and this of course laid them under a necessity of seeking for means to remedy the defect. They found the plough the most ready and perhaps the most effectual: and hence all the ancient writers so highly commend a thorough ploughing. At the same time the apparent loss of the produce of the ground,

during the year of fallow, put them upon enquiring how this inconvenience might be prevented, consistently with keeping the land in good heart. Repeated observations convinced the Romans, the most attentive of all nations to every thing relative to husbandry, that, besides the alternate resting of the land, wheat may, as Pliny observes, be sown after lupines, vetches, beans, or any other plant which has the quality of fertilizing and enriching the soil. This, says Mr. Lisle, deserves to be well noticed, because our farmers imagine they cannot make their rent, if they pay twelve shillings an acre, without sowing their land every year; nor will they be persuaded to lay it down to grass.

A judicious change of crops, is without doubt of great importance in the common tillage husbandry; as they enable the farmer to save the expence, and loss of crop in the fallow year; and to conquer his great enemies the weeds, by attacking them at different seasons in the year, and in different periods of their growth; especially when the intermediate crops are hoed, as those of beans and pease; for the repeated hoeings not only destroy the weeds; but also very much enrich the land. The benefit of changing the crops appears to arise from these, and the other circumstances above-mentioned, rather than from the different food that the several crops are supposed to extract from the soil; because the new husbandry proves, that the same kind of crops may be continued, without change, from year to year in that husbandry, so long as the hoeing culture is continued.

The most rational change of crops hitherto pointed out by any writer, is the following, planned by Camillo Tarello, and which he presented to the senate of Venice in the year 1566:

"Let the ploughings; hitherto given to corn-land divided into two portions (each of which being rested every alternate year, receive four ploughings that year) be transferred to the half of one of those portions; so that it be ploughed eight times, including the seed-ploughing; I mean that every farm in tillage be divided into four equal parts; and that only one of these parts, taking them alternately, be sowed with corn in any one year, after it has been ploughed eight times. Two of the other parts should be laid down to grass, and the fourth should be fallowed a year, during which it should receive the above-mentioned number of ploughings.

"He therefore who has now, for example, ten acres under corn, should for the future sow only five, and so in proportion for a larger or lesser extent; and all the manure and labour formerly bestowed upon his ten acres should be appropriated to the five only; that is, he should plough them eight times, unless the soil be extremely light.

"The husbandman should begin to plough in October or November, about ten months before he sows, or sooner if he can; but always in dry weather. He should lay on his dung before the last ploughing; and should not sow more than two thirds of the quantity of seed hitherto commonly used, and that seed should be of the growth of the country.

"Whoever follows this method may always depend of reaping the following advantages:

"1. This way of cultivating land lessens the expence and labour, it being easier to plough one acre eight times, than to plough two acres four times each; because, after the third time, an acre and a half at least may be ploughed as soon as an acre could have been before; and if he begins his work in October or November, while the land is in good condition for ploughing, he may continue it the following year, at such times as he will have little more urgent business, so as to have four ploughings done about the end of May. By this means the four summer ploughings will not require such strong ploughs as some people now use, to the great hurt of their cattle, and fatigue of the ploughman, because the ground will be already well loosened.

"2. These repeated ploughings will destroy the seeds and roots of weeds, which rob the corn of its food, choke it, and hinder it from growing.

"3. A field rested, and then prepared in this manner, will yield more than double the produce of two equal spaces of land cultivated in the common manner, as I have often experienced. This is more than doubling one's income.

"4. Over and above this great advantage, we likewise save two-thirds of the quantity of seed hitherto commonly used; for by sowing only a quarter instead of half of the
the

the land in tillage, there is an immediate saving of half of the seed formerly required; and by sowing only two-thirds of the usual quantity upon that quarter, we again save two twelfths, that is, one sixth of all the former seed: now half and one sixth makes two thirds, to be deducted from the former usual quantity.

" 5. We shall have a sufficiency of straw of every kind for all our uses; especially for litter and dung, so indispensably useful.

" 6. We shall have hay and fodder enough to keep many cattle, because we may, and should sow one half of our ground with grasses, which will thrive extremely well, while the land is thus rested for two years, in order to be afterwards broken up, ploughed, and sowed with corn in its turn: for I again advise sowing only a quarter part of the whole farm with corn, and breaking up another quarter immediately after seed-time, before winter; and, on the contrary, neither of the other quarters should be ploughed during two years. But as the earth is destined continually to yield productions of one kind or another, even while it rests, we shall do well in following the path pointed out by nature, by helping it to produce clover, and other plants fit for fodder, which are of singular service to us, not only on account of the hay we reap from them, but also because their roots greatly improve the soil. In the country about Brescia, plentiful crops of the finest flax are reaped from fields where a quantity of clover has been lately mowed; and lands are let there for a great price, not only because the soil is rich, and can be watered, but also because it has just been under clover. If such value is set upon land intended only for flax or millet, how much more would good wheat-land justly deserve?

" 7. A seventh advantage will be, that land rested regularly for two years (I say, with Virgil, that it rests when it is not ploughed) being well-conditioned, afterwards well prepared, ploughed, enriched by the roots of the grasses, and kept clear of weeds, will yield crops more than twice as great as any we now reap; a truth which I have practically experienced, which the most sensible and most judicious husbandmen that ever lived have long told us, and of which a trial will soon convince the most incredulous.

" 8. One of the most considerable advantages attending this method, is the ease with which a great number of cattle may be reared, by means of the increased quality of hay and green fodder. We shall consequently have more horses, more oxen, more cows, more sheep, and more poultry. Every one knows of what infinite service all these are, to feed us, to cloath us, and to help us in our work. He, therefore, who has hitherto been obliged to have two yoke of oxen, will, in this method, want only one, and may, instead of the other, feed two or three cows: for as the labour is hereby lessened, and the quantity of good fodder increased, two oxen will be sufficient to plough the land, especially as the soil will by this means be brought daily into better and better tilth.

" 9. From hence naturally arises a ninth advantage, which is, the quantity of manure produced by the increase of cattle and fodder; an advantage which no good husbandman will neglect to purchase, if the means of doing it are but pointed out to him.

" The tenth and last of the advantages which I shall here enumerate, as resulting from this new method of culture, is, that poor and barren lands are hereby rendered, by degrees, good and fertile: for such is the constitution of the earth, that ploughing and manuring alter its very nature, and improve it more and more, as experience repeatedly demonstrate. Valerius Maximus instances the striking example of Masinissa king of Numidia, who made agriculture flourish so much, that he left his country, which he found barren and desolate, stored with riches and every good thing. It is in our power to do the same. On the contrary, it is not less true, that even though the earth be rich and good, it will yield but little fruit, if it be not well cultivated; resembling therein the capacity of the human mind, which, according to Cicero's fine comparison, is enlarged only by study and exercise. Industrious labour will not only procure us the necessaries, nay the superfluities of life, but will even change a barren country into a kind of garden." *Ricordo d'Agricoltura di Tarello.*

M. Duhamel, after observing that the French farmers, in general, change their crops, not on any principle dictated by reason, but merely because it was the custom of their forefathers, or they themselves perhaps have occasion for

some particular growth, draws a parallel between the practice of dividing arable land into three part, or into two, in order to their being alternately sown, and rested. "I have," says he, some acquaintance with the methods of practice in Guienne and in part of Normandy; and am obliged to M. le Baron de Sournia, governor of Querebus, for enabling me to give an account of the methods used in the neighbourhood of Perpignan, where his estate lies.

" In this hot climate they sow their lands in September, and begin to cut wheat about the 10th of June; so that their harvest is generally finished by Midsummer.

" They divide their lands into two portions only; so that in one year they sow wheat, and the other the land should be suffered to rest. But, on such part of their lands as are most valued, they have several crops during the year of rest: this impoverishes their lands, and they are obliged to sow their wheat too late, which lessens the crop. We shall mention an instance given by M. Sournia.

" In land they can water, they sow clover immediately after wheat-harvest, scattering the clover-seed among the stubble. The land is then immediately watered, and is afterwards several times repeated during the summer: in the winter they feed it with sheep and lambs. Such as have no flocks sell their pasture to the upland farmers, who have flocks but no winter fodder, their land being covered with snow: this pasture therefore fetches a very high price.

" In spring, when the green fodder has been eaten down by cattle, they water the land, and by that means the clover sprouts apace; when it is in blossom they mow it, make it into hay, and lay it up with the rest.

" Immediately after this crop, they dung the land; and such as are not afraid of exhausting it, plough it, and sow either kidney-beans, or small millet: but as they cannot plough for wheat till these crops are off the ground, there is not time sufficient for giving the land proper tillage, the sowing is retarded, and the rich particles of the dung are partly consumed by these crops, while the manure might be more usefully employed on lands they cannot water. M. de Sournia is, by repeated experience, convinced that, to have good crops of wheat, they must be contented with the crop of clover, and only sow kidney-beans, millet, &c. in small quantities for the use of the family.

" In Guienne, as well as in Anjoumois, they raise a crop of maize, which is a great impoverisher of the ground, during the year of fallow.

" The good husbandmen also think, that in the rich lands, which they cannot water, it is the best, in a farm of three hundred and fifty acres of wheat, to be careful to give proper tillage to the one hundred and fifty acres that should be in fallow, to make them proper for the reception of wheat. This is also the practice of some districts of Normandy, where the climate being colder, and the soil more backward, they have scarcely an opportunity of having any crop but wheat. However, when the land has been well dunged and tilled for maize, as they bestow three ploughings on that plant, there is commonly the next year a very good crop of wheat.

" It is evident, that by dividing a farm that has three hundred acres in tillage, into two equal portions, which are sown alternately every other year, the tenant, during a nine years lease, will reap one thousand three hundred and fifty acres of wheat; whereas, if the land be divided into three portions, it will amount to nine hundred acres only. But in the latter case, the former has nine hundred acres of spring corn, which being estimated at half the value of the wheat, make it just equal to one thousand three hundred and fifty acres of wheat. It follows therefore, that in grazing countries, where they plough with oxen, and use but few oats, it is most advantageous to divide the land into two portions; but that this is not to be done in farms that are tilled with horses, because the necessary purchase of oats would amount to the value of four hundred and fifty acres of wheat extraordinary.

" The farmers about Bayeaux, in Lower Normandy have two methods of changing their crops.

" According to one of those methods, 1. They sow buck-wheat towards the end of June. 2. When the roots and stems of this plant are dead and withered, which is about All-Saints day, they plough, and immediately sow wheat: the wheat is therefore sown on one single furrow. These lands have indeed been ploughed for buck-wheat, and even thoroughly dunged; and plenty of manure can supply the place

place of good tillage, and the latter can supply the place of the former. 3. After reaping the wheat, they plough in the stubble as soon as possible; and, after giving the land a second ploughing in February or March, they sow it with oats; or a third ploughing is bestowed upon it, in order to crop it with barley. 4. They plough in the barley stubble in winter, and after giving the land one spring ploughing, sow either peas or tares. 5. Immediately after this crop is off, they turn down the land, that it may receive two ploughings before October, when it is sowed with wheat. 6. The following year they sow oats mixed with a little clove-seed; after which it is laid down in pasture for three or four years. It would be needless to mention that the farmer varies the order of his successive crops, according to the nature of the soils, and his own occasions; but by this method six crops are reaped in six years; two of wheat, two of oats, one of buck-wheat, and one of peas or turneps; and the field is then left in clover to be fed for four years.

"According to the other method, they sow no buck-wheat on the land they break up; it is left in fallow from February or March, when it is turned up, till October; and during this interval they manure it, and give it several ploughings to prepare it for wheat. In this case the crop is generally more plentiful than when buck-wheat has been sown. In other respects, the change of crops is the same as was mentioned before." *Culture de Terres, tom. VI. p. 34.*

The changing of crops, upon rational principles, though of infinite consequence in agriculture, seems to have been neglected, and even forgotten, after the time of the ancient Romans, till Camillo Tarello pointed out its great importance, as we have already observed in this article; nor do we, since him, find much attention paid to this essential part of husbandry, till very lately, when the culture of turneps probably gave the useful hint; the farmer observing, that his land, instead of being impoverished by that root, was enriched, and prepared to yield a better crop of barley in the spring. This might naturally suggest to him, that other succulent plants, which cover the earth with their leaves, might have the same effect. The success has answered his utmost expectation: for it is now found that a fallow does not become necessary in several years; the ground being kept in heart by a variety of crops, when rightly timed, and properly managed. The Society for the Improvement of Agriculture in Scotland, from whom we shall borrow the following judicious instructions, have the honour of setting this discovery in its proper light.

They observe, "That some crops, as peas, beans, clover, and all plants of the pulse kind, are enrichers and cleaners of the earth; while wheat, oats, barley, and the whole tribe of vegetables, whose roots are fibrous, and spread far, impoverish and rob the ground. The latter are also foul-ers of it, by giving way to weeds and grass, which, being the natural product of every soil, are more readily nourished by it than any plant which it does not spontaneously produce; and if the earth be fed with any sort of manure, it will, while the weeds and grass remain undestroyed, like a tender mother, cherish and nourish them in proportion to the food she receives.

"Wheat and oats are great robbers of soils. Wheat remains a long time in the ground, during which the land untills itself, coalesces, and becomes of the nature of uncultivated earth; while the weeds, meeting with no opposition, ripen, and shed their seeds. Oats do not continue so long: but they bind the soil by their strong roots, and give many weeds time to ripen. Barley, as it stands only a few months, and several ploughings are given for it, binds the earth less than either wheat or oats. Peas, beans, tares, &c. are supposed to draw much of their nourishment from the atmosphere, and that in proportion to the succulency of their stems and leaves, whereby it is probable their roots discharge a moisture under ground; and their leaves, covering the surface of the earth, return the moisture and dews descending through them, which mellow and rot them into a kind of manure." *Maxwell's Collection, p. 219.*

From the above observations, the farmer will be able to vary his crops in such a manner as always to keep his ground in heart, and free from weeds; particulars which cannot fail of producing very great advantages.

CHANNEL, of a horse, is the hollow between the two bars of the under jaw-bone, in which the tongue is lodged.

CHARCOAL, a sort of fuel, consisting of wood charred, or half burnt.

The dust of charcoal has been found, by repeated experience, to be of great benefit to land, especially to such as is stiff and sour. It is to be used in the same manner as foot and wood-ashes. See the articles ASHES and SOOT.

Mr. Marshall, in his Rural Economy of the Midland Counties, says, "that great quantities of charcoal are still used in the iron forges of this country: for although it has been discovered that iron, for common use, may be made with pit-coal; yet, for particular purposes, where a toughness of texture is wanted, as for wire-drawing, &c. charcoal is found to be requisite.

"In this country there are sets of men whose trade is the burning of charcoal. They cut and cord in the winter, and burn during the summer season.

"The minutiae of the process is this: The site or hearth being determined upon, the turf is pared off, and the sods laid on one side. The wood, about ten cord, is then laid in a ring, somewhat wider than the intended hearth; beginning on the outer circumference of the ring, with the smallest of the round wood, laying the larger pieces of top-wood, and the cloven roots or butt-ends, towards the center. With these last, some of them nearly as large as bushel-blocks, they begin to make their pile, leaving a kind of chimney in the middle (a vertical aperture from a foot to eighteen inches wide), and round this core of roots set up the top-wood (which has previously been cut at the time of cording, in such a manner that no forkedness nor other awkward crookednesses are left; or, if not cut in this manner, or cut improperly, it is prepared by the colliers themselves, previous to laying it ready for setting), joining the blocks, or rather fitting them in, as close to each other as possible; placing the convex side of the logs outward, forming the pile in the shape of an inverted bowl, nearly semiglobular.

"The pile being formed, it is tiled with sods; which are pointed, to keep in the heat the better, by filling up the seams with fine pulverized mould.

"The chimney is now filled with short pieces of dry wood; near the top a live coal is put; over this one layer more of dry pieces; and, upon these, a close cap of sod is placed: nevertheless, this one coal, not larger than the fist, and excluded from the open air, is sufficient to set the whole pile on fire.

"As the pieces in the chimney burn away, they are replaced with fresh ones: thus feeding the fire with fresh fuel.

"Paled hurdles are placed on the windward side of the heap, to prevent the fire from acting partially.

"When the fire begins to work itself out, at the outward skirts of the bottom of the pile, it is known that the coal is fully burnt (or rather the wood sufficiently charred) which it will be, in a pile of ten cord, and in fine dry weather, in seven or eight days.

"The fire, during the whole time, is carefully kept from breaking out, by throwing mould or ashes upon the weak part: so that, though the fire passes through every part of the wood, little or none of the phlogiston, or matter of fire, escapes.

"It is observable, that notwithstanding the intense heat, no part seems to be consumed; not the bark only, but even the moss upon it, comes out as entire as when it went in; the only apparent change is in its being rendered friable, and of a black colour. Wood that is charred seems to be only very highly dried. It shrinks considerably during the process of charring; but there is no visible derangement of parts. One of the smaller pieces, which is not broken in the drawing, appears as entire when it comes out as when it went into the pile. The brittleness after charring, however, shews that the texture of the wood is altered by the action of the fire.

"As soon as the fire is out of the coal, on the outside of the heap, the workmen begin to draw; which is done by running a peel between the coal and the hearth, raising up the coal in such a manner as to let the mould and ashes of the sods fall through between the pieces, upon the inward parts still full of fire. If this makes its appearance in any particular spot, a peel full of ashes is immediately thrown against it.

"Having got sufficiently near to the fire, the coals raised by the peel are raked off with long wide-toothed iron rakes; the teeth about a foot long, and standing about six inches

inches apart; the handle and head of wood, except a plate of iron on the back, with which the small coal is gathered together. No sieve, nor any rake with finer teeth than the above, is used. The coal being light, it is readily brought to the surface of the ashes and dirt; and, being there, is easily collected (though with a kind of slight) with the back of the rake.

"The side, thus drawn, being rounded up and secured with ashes, another, the coolest part, is drawn in the same manner.

"The drawing is an infernal business: the men work among fire and phlogiston enough to suffocate Satan himself.

"Such pieces as still retain fire, after they are drawn, are quenched with water; which the workmen have in plenty standing by them, in pails. If a large piece contain much fire (which hides itself chiefly in the chinks of the large pieces), it is plunged, bodily, into the water. If the heap itself prove too refractory to be kept under by the ashes alone, a sufficient quantity of water is thrown upon it, to keep the fire under. Such large pieces as are suspicious are laid on one side; in order that those which take fire may be the more readily discovered.

"A waggon attends to take away the coal, as fast as it is drawn. For, if it take fire, or get wet, in the hands of the burners, it is at their risque: and while in the waggon, it is at the risque of the waggoner. Every particle burnt is so much entire waste.

"The quantity of ashes arising from a charcoal hearth is considerable. There has been already four cart loads taken up from two small hearths, and a load or two more remaining.

"Charcoal ashes are in good esteem, here, as a manure; particularly for turneps, and for fining grass land. They arise principally from the sods used in covering; but, in part, from the bits of coal which break off in raking it out of the ashes."

CHARLOCK, called also *Chadlock*, *Catlock*, *Corlock*, and *White Rape*, is a weed too generally known to need a particular description: the figure we have given of it on plate V. fig. 32. will be abundantly sufficient. Almost the whole plant is covered with bent pellucid hairs.

There are two sorts of charlock, one bearing white, and the other yellow flowers; but they seem to be only a variety of the same plant. The young plants of charlock so nearly resemble those of turneps, that they are not easily distinguished but by the taste; the charlock being hot and bitter, and the turnep mild. Farmers should therefore be very careful in weeding their turneps, lest they mistake them for charlock.

Mr. Lisle observes, that cold wet lands are always more subject to charlock than white or chalky lands: because the charlock-seed being very oily, resists putrefaction, and is not easily opened or penetrated by moisture, whereas white and light earth is soon dry after rain, and the water does not continue long enough on it to make such seed germinate so effectually as in the other. By an experiment which he made in sowing charlock-seed and turnep-seed at the same time, he found that the turneps will appear in three days, but the charlock in not less than ten. A hint that may prove very useful to the husbandman." *Lisle's Husbandry*, vol. II. p. 297.

Mr. Mortimer after remarking that both the white and yellow charlock are very prejudicial to corn, and that some lands are very subject to it, especially if manured with cow-dung alone, which he thinks increases it more than any other manure, unless it be mixed with horse-dung, or some other hot manure, mentions his being told of a person who had vast quantities of this weed in a field of barley, mowed the whole when the charlock was in flower, and ready to seed, which is commonly about the middle of May, as low as he could, without taking off more than just the tops of the blades of the barley; and that this gave the corn an opportunity to get above it, in such a manner, that he had four quarters of barley on an acre. He adds, that where a fallow is full of charlock, it will be right to turn in sheep, which will eat it very readily. *Mortimer's Husbandry*, vol. I. p. 311.

Charlock is a more agreeable food to sheep than turneps: for I have seen where sheep have broke into a field of turneps, they have eat down the charlock almost to the ground, and have not touched any of the turneps.

CHASE, a word used in some counties to signify a row or rank. Thus in the planting of quicksets, a single chase implies a single row; a double chase, means another row planted below the first, not immediately underneath the up-

per plants, but under the middle of the intermediate spaces. *Lisle's Husbandry*, vol. II. p. 405.

CHATS, the keys of trees, such as the ash, sycamore, &c.

CHEDDER-CHEESE, a name given to a very large kind of cheese made at Cheddar, a village near Mendip-hills in Somersetshire, famous for its pastures. It is common in this place for three or four dairies to join their milk to make one great cheese, which generally weighs from one hundred and fifty to two hundred weight; and which they often sell at six-pence per pound on the spot.

CHEESE, a well-known species of food, prepared from curdled milk, pressed from the whey, and afterwards dried for use.

Mr. Marshall, in his *Rural Economy of Norfolk*, says, "To render my residence more commodious, as well as to gain some information on the subject of cheese-making, an art I was then a stranger to, I rented a small dairy of cows. I took them the rather as I had then in my service an excellent Wiltshire dairy-woman: who, I was in hopes, might be able to make some improvement on the Norfolk method of making cheese; which, I had been given to understand, was execrable.

"Having long considered this interesting subject as being allied to experimental philosophy, I placed it in that light, and paid as much attention to the different processes as an active scene of employment would permit me. What I have been able to do is only an essay; but it is sufficient to convince me, that with leisure and application, much might be done towards bringing this, at present mysterious, but important subject to some certain and fixed principles.

"In registering the information I have been able obtain, to it will be proper to digest it under the following heads:

The preparation of the rennet.

The coagulation of the milk.

The management of the curd.

The management of the cheese.

"The curd which happens to be contained in the stomach of the calf when butchered, together with the hairs and dirt which are inseparable from it, are used by the dairy-women of this country to coagulate their milk: hence, probably, the rancid flavor of the Norfolk cheese; perfectly resembling in scent the parent curd; and this, as nearly as may be, its more matured self.

"The rennet which I made use of was prepared in the following manner:

"Take a calf's bag, maw, or stomach; and, having taken out the curd contained therein, wash it clean, and salt it thoroughly, inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days; in which time it will have formed the salt and its own natural juices into a pickle. Take it out of the jar, and hang it up for two or three days to let the pickle drain from it; resalt it; place it again in a jar; cover it tight down with a paper pierced with a large pin; and in this state let it remain until it be wanted for use. In this state it ought to be kept twelve months: it may however, in case of necessity, be used a few days after it has received the second salting; but it will not be so strong as if kept a longer time.

"To prepare the rennet for use; take a handful of the leaves of sweet-briar, the same quantity of the leaves of the dog rose, and the like quantity of bramble-leaves; boil them in a gallon of water, with three or four handfuls of salt, about a quarter of an hour; strain off the liquor, and, having let it stand until perfectly cool, put it into an earthen vessel, and add to it the maw, prepared as above. To this is added a sound good lemon, stuck round with about a quarter of an ounce of cloves; which give the rennet an agreeable flavor.

"The longer the bag remains in the liquor, the stronger of course will be the rennet: the quantity, therefore, requisite to turn a given quantity of milk, can only be ascertained by daily use and observation.

"When the rennet is sufficiently strong take out the bag; hang it up two or three days for the rennet to drain from it; resalt it; put it down again into the jar; and thus continue to treat it, until its virtues are exhausted; which will not be until it has been used several times.

"By sufferings one or more bags to remain in the liquor, the rennet thus prepared may be raised to a very high degree of strength, as will appear in the following observations.

"The leaves and the spice, it is probable, have no other effect than that of doing away the ill flavor of the maw; which

which, if ever so well cleaned, retains a faint disagreeable smell ; whereas the rennet prepared as above, is perfectly well flavored.

" It is however, I find, an idea among the Wiltshire dairy-women, that the leaves correct any rankness or evil quality in the milk, arising from a rankness of pasture : they being further of opinion, that different pastures require different sorts of herbs to correct them ; and some of them, it seems, are, or pretend to be, so deeply versed in this art, that they will undertake to correct any milk, so as to prevent the rising, heaving, or blowing of the cheeses made from it ; and, consequently, the rancidness which usually accompanies a porous cheese.

" This is, no doubt, a grand object of cheese-makers ; but it is not, I apprehend, to be obtained by so small a proportion of vegetable juices as pass with the rennet into so large a proportion of milk. Nevertheless, it appears to me highly probable, that this grand desideratum lies within the reach of the chemical art ; and that by a course of judicious experiments, some vegetable or mineral preparation, adequate to this valuable purpose, may be discovered.

" Coagulation. Next to the art of correcting the milk (an art as yet in its infancy) seems to claim the attention of the experimentalist.

" It is known, from daily experience, that the warmer the milk is, when the rennet is put to it, the sooner it will coagulate, with a given quantity of rennet of a given strength.

" It is equally well known that the cooler the milk, and the longer it is in coagulating, the more tender and delicate the curd becomes : on the contrary, if the milk be too hot, and the coagulation takes place too rapidly, the curd proves tough and harsh.

" But it seems to be a fact, equally well established, that a cheese made from milk, which has been coolly and slowly coagulated, is longer before it become marketable than one made from milk which has undergone a less deliberate coagulation ; and which, being drier, and of a harsher texture, sooner becomes cheesy, and fit for the taster.

" Therefore the great art in this stage of the process lies in—

The degree of warmth of the milk when *set* ; that is, when the rennet is put to it ; or, in—

" The degree of heat retained by the curd when it *comes* ; that is, when the coagulation has sufficiently taken place ; or, in—

" The length of time between the *setting* and *coming*. Which length of time may be regulated either—

" By the degree of the warmth of the milk when *set* ; or—

" By the state of warmth in which it is kept during the time of coagulation ; or—

" By the quantity and strength (taken jointly of the rennet.

" To endeavour to gain some information on this subject, I made the following observations :

" 1781. June 5. Twenty-three gallons of milk, heated to ninety-six degrees of Fahrenheit's scale, with two tea-cup-fulls of weakish rennet, came in one hour ; the curd delicate and good.

" June 6. The same quantity of milk, of the same heat, with the same quantity of rennet, came in nearly the same time ; the curd somewhat tough ; owing, probably, to the milk having been burnt to the kettle in which it was heated.

" June 7. Twenty-seven gallons of milk, heated to ninety-four degrees, with the same quantity of rennet, came in about two hours ; the curd very good.

" June 8. Twenty six gallons of milk, heated to one hundred and two degrees, with one tea-cup-full of rennet, came in two hours and a half ; curd very good.

" June 9. Twenty five gallons of milk, heated to one hundred degrees, with a tea-cup-full and a half of rennet, came in about one hour and a half ; the curd good, but somewhat tough ; owing, perhaps, to the milk being kept too warm in the cheese-tub, by being covered up close with a thick cloth.

" Note, on the seventh and eighth, the whey retained a heat of about eighty-eight degrees, whereas the whey this morning was ninety-two degrees : so that, perhaps, it is not the heat when it is *set*, but the heat when it *comes*, which gives the quality of the curd.

" June 10. Twenty-five gallons : ninety-six degrees : two cups : uncovered : came in two hours and a quarter : whey eighty-seven degrees : curd very tender.

" June 11. Twenty-three gallons : one hundred degrees : more than a tea-cup : uncovered : did not come in two hours ; owing to the rennet being lower in strength than before : therefore, added in a little more rennet : which brought it in about three hours from first setting ; the whey eighty-seven degrees : the curd uncommonly delicate.

" June 12. Twenty-four gallons of milk : one hundred degrees : two cups of rennet : uncovered : came in two hours : whey eighty-nine degrees : curd uncommonly tender.

" June 13. Twenty-eight gallons of milk : ninety-two degrees : three cups (lay strongly renneted) : covered up with a coarse linen cloth : came in one hour and a half : whey eighty-six degrees : curd very good, and of a very fine colour : though perhaps would have handled tenderer, if it had not stood some time, after it came before it was broke up.

" Perhaps much depends on its being broke up in the critical minute.

" June 14. Twenty-eight gallons : one hundred degrees : two cup-fulls : uncovered : came in one hour and a quarter : whey ninety-four degrees : curd somewhat harsh, but of a good colour.

" The change of colour is therefore owing to the change of pasture.

" Note, The milk should be covered to make it come together : this came and grew hard at the bottom, half an hour before it was set at the top.

" June 15. Twenty-eight gallons : milk heated to ninety five degrees : with two cups of rennet ; and covered after it had stood three quarters of an hour : came in one hour and a half : whey eighty-nine degrees (the morning warm) : curd very good and tender.

" June 16. Thirty gallons of milk heated to one hundred and three degrees ; but lowered by two pails-full of cold water to ninety-six degrees ; with two cups and a half of rennet ; and kept close covered : came in one hour : whey ninety-four degrees : curd pretty good but not sufficiently tender.

" June 17. Twenty-eight gallons : ninety seven degrees : two and one-half cups : covered ; but not close : came in one hour and a half : whey not tried : curd somewhat tough.

" Note, the toughness is owing, perhaps, to some milk of a new-calven cow being among it.

" Note also, to try the exact heat of milk immediately from the cow, immersed a dish in the pail while milking. After it had lain long enough to receive a degree of heat equal to that of the milk in the pail, emptied it, and immediately milked into it from the teat (the cow being at this time about half milked) ; the heat ninety-five degrees.

" Note also, the cheeses of yesterday (the 16th of June) press remarkably elastic, and spongy (like a fungus) : perhaps owing to the milks coming too hot ; or perhaps to two or three of the cows being then a-bulling ; or perhaps, being made thicker than usual, the press was not heavy enough for them ; or perhaps this ill quality is owing to the cold water being put into the milk.

" I afterwards found that milk of a cow, on the day of amour, retained, after having stood some times in the pail after milking, ninety-eight degrees of heat. This shews that the state if not the quality of the milk is altered by the heat of the cow ; and a cautious dairy-woman always endeavours to keep such milk out of her cheese-tub.

" June 18. Thirty gallons : ninety-five degrees : covered : came in one hour and a half : whey ninety-two degrees : curd pretty good.

" June 19. Thirty gallons : ninety-two degrees : two cups covered : curd very good.

" June 21. Thirty gallons : ninety-eight degrees : lowered by half a pail of cold water of ninety-five degrees : the curd good ; but the cheeses like those of the 16th press, hollow and spongy.

" Therefore, it is probable, from these two incidents, that lowering the heat of the milk with cold water has an evil effect.

" June 23. (Evening) fifteen gallons of new milk warm from the cow, retaining a heat of ninety-two degrees, with two cups and a half of new weak rennet, and closely covered, came in three quarters of an hour : whey eighty-eight degrees : curd very delicate and good.

" June 25. Forty gallons of half-skim milk, heated to eighty-seven degrees, with three cups of rennet, slightly covered, came in three quarters of an hour : whey seventy-

seventy-nine degrees : curd remarkably good of this sort.

" Sept. 8. In observing the effect of some remarkably strong rennet, I found that an ordinary tea-cup-full coagulated sufficiently upwards of forty gallons of milk, heated to only eighty-eight degrees, in thirty-five minutes.

" From these observations it appears, that curd of a good quality may be obtained from milk heated from 87 to 103 degrees of Fahrenheit's thermometer ; provided the rennet be so proportioned, that the time of coagulation be from three quarters of an hour to two hours and a half ; and provided the milk be kept properly covered during the process of coagulation.

" And from these as well as from a variety of other observations, which I made in the course of the summer, but which are not minuted, it appears to me, at present, that from 85 to 90 are the proper degrees of heat ; that from one to two hours is the proper time of coagulation ; and that the milk ought to be covered so as to lose in the process about 5 degrees of its original heat.

" But climate, seasons, the weather, and the pasture, may require that these bounds should sometimes be broken. A few observations, made in one season, and in one place, how accurately soever they may have been taken, are by no means adequate to the entire illustration of this very abstruse subject.

" In Norfolk this stage of the process is very short. Part of the whey being laded off, the remainder, with the curd, is poured into a cloth : the whey drains through ; the curd is shook in the cloth ; kneaded down into a vat ; put under a light press, or perhaps under a stone ; the cloth once changed ; the curd once turned ; and lo ! a Norfolk cheese appears. The cows are milked and the cheese completed in ten or twelve hours.

" The practice in my dairy has been uniformly this, as soon as the curd is come at the top, firm enough to discharge its whey, the dairy-woman tucks up her sleeves, plunges her hands to the bottom of the vessel, and, with a wooden dish, stirs the curd and whey briskly about : she then lets go the dish, and, by a circular motion of her hands and arms, violently agitates the whole ; carefully breaking every part of the curd ; and, at intervals, stirs it hard to the bottom with the dish ; so that not a piece of curd remains unbroken larger than a hazel-nut. This is done to prevent what is called slip-curd (that is, lumps of curd which have slipped unbroken through the dairy-woman's hands), which, by retaining its whey, does not press uniformly with the other curd, but in a few days (if it happen to be situated toward the rind) turns lived and jelly-like, and soon becomes faulty and rotten. This operation takes about five or ten minutes ; or, if the quantity of curd be large, a quarter of an hour.

" In a few minutes the curd subsides, leaving the whey clear upon the top. The dairy-woman now takes her dish, and lades off the whey into the pail ; which she empties into a milk-lead to stand for cream, to be churned for whey butter.

" This is a practice peculiar to the cheese counties, and forms no inconsiderable part of the profit of a dairy in those counties. In Norfolk, the whey, even from new milk, passes from the cheese-vessels immediately to the hog-tub.

" Having laded off all the whey she can, without gathering up the small pieces of the loose curd floating near the bottom of the vessel, she spreads a straining-cloth over her cheese-tongs, and strains the whey through it, returning the curd retained in the cloth into the cheese-tub. When she has got all the whey she can, by pressing the curd with her hand and the lading-dish, she takes a knife and cuts it into square pieces, about two or three inches square. This lets out more of the whey, and makes the curd handy to be taken up, in order to be broken into the vats.

" A dairy should be plentifully furnished with vats, and some of them of different sizes ; for when three or four cheeses are made at each meal, a number of vats become actually in use ; and if there are not still a number empty, the dairy-woman becomes confined in her choice, and cannot proportion exactly her vats to the quantity of curd she happens to find in her cheese-tub ; and keeping a little overplus curd from meal to meal frequently spoils a whole cheese.

" Having made choice of a vat or vats, proportioned to the quantity of curd, so that the cheese, when fully pressed, shall neither over nor under fill the vat, she spreads a cheese-cloth loosely over the vat ; into which she re-breaks the curd ; carefully squeezing every part of it in her hands ;

and, having filled the vat heaped up and rounded above its top, folds over the cloth, and places it in the press.

" Much depends on the construction and power of the press. The excellency of construction depends upon its pressing level : if it has too much play, so as to incline and become tottering or leaning one way or another, and do not fall perpendicular upon the cheese-board, one side of a cheese will frequently be thicker than another ; and, what is still worse, one side will be thoroughly pressed while the other is left soft and spongy. Its power may be given by a screw, by a lever, or by a dead weight, and ought to be proportioned to the thickness of the cheese.

" I had one constructed on the above principles ; the power, a dead weight of stones, contained in a cubical box, moving in grooves so as to keep its bottom horizontal ; the medium weight, 1 cwt. 2 qrs. but regulated, by the stones, agreeably to the thickness of the cheese or cheeses to be pressed.

" In autumn, when the weather got cool and moist, the curd was scalded, to make the cheese come quicker to hand, (that is, sooner saleable) and to prevent a white woolley coat from rising. It is done thus : If from new milk, scalding water (boiling water with a small quantity of cold whey mixed with it) is poured over the whole surface of the curd as it lies at the bottom of the cheese-tub : if from skimmed or other inferior milk, the outsides only are scalded, after the curd is in the vat, by first pouring the scalding water on one side, and then, turning the cheeseling, pouring it on the other. For if in this case the curd were to be scalded, it would render it hard, and spoil the taste and texture of the cheese. In the scalding the cheeseling, the curd is first put into the bare naked vat, and the upper part scalded : the cheese-cloth is then spread over it, and the vat being turned, the curd falls into the cloth : the curd, with the cloth under it, is then put into the vat ; the outer edges pared off ; the paring broke, and rounded up in the middle ; and the scalding water poured upon it as before ; the folds of the cloth laid over, and the vat set in the press.

" The whey being pretty well pressed out, and the cheeseling (whether it has been scalded or not) having got firm enough to handle, which it will be in about half an hour, the dairy-woman takes it out of the vat ; washes the cloth in a pail of clean cold water ; spreads it over the vat ; turns the cheeseling upon it ; squeezes it gently into the vat ; folds over the cloth ; tucks in the corner with a wooden cheese-knife and replaces the vat in the press.

" Supposing the cheeseling to be made in the morning, it now remains in the press, untouched, until the evening ; when it is taken out, salted, put into a fresh dry cloth, and left in the press all night.

" The method of salting is this : The salt being well bruised, and the lumps thoroughly broken, it is spread plentifully on each side of the cheeseling, so as wholly to cover it, about one-tenth of an inch in thickness, more or less, in proportion to the thickness of the cheese. If this be of a considerable thickness, as suppose three inches and upwards, some salt is put into the middle of it, by stopping when the vat is half filled with curd, strewing on the salt, and on this putting the remainder of the curd.

" Next morning, if the curd be rich, or has been cold-run, the cheeseling is turned into another dry cloth, and left in the press till evening : but if on the contrary the curd be from poor milk, or from milk which before setting had acquired any degree of sourness, or if it has been run hot and quick, the cheeseling should in the morning be bare-vatted ; that is, be put into the vat without a cloth round it, and be put again into the press until evening.

" The use of bare-vatting is to take out the marks of the cloth, and thereby evade a waste of labour in bringing the cheese to a smooth glossy coat. The reason for the above distinction is, therefore, obvious ; for the harder the curd, the longer the marks of the cloth are in pressing out.

" In the evening, that which was turned into the dry cloth in the morning, is now bare-vatted ; and that which was bare-vatted in the morning, is now turned in the vat ; and, having stood in the press until morning, the process is finished. The cheeses are taken out of the vats, and placed upon the shelf.

" Thus, supposing the cheeseling to be made on Monday morning seven o'clock, it is, between eight and nine, taken out of the vat ; the cloth washed ; and immediately placed in the press again. On Monday evening, it is salted, and, if wanted, pared ; put into a dry cloth ; and replaced in the press. On Tuesday morning it is bare-vatted, or the cloth changed ;

ed; the cheesling, in either case, being turned, and again put into the press. On Tuesday evening it is again turned; and on Wednesday morning finally taken out of the vat and press.

"The objects of this most laborious department of cheese-making are, to preserve the cheese sound in itself, and to give it such an appearance as will recommend it to a purchaser.

"Cheeses newly made, naturally acquire a white scurfy coat; which, besides hiding, if not causing, the defects of the cheese, is at least unsightly, and is a certain mark of the slovenliness of its maker. This scurf arises more plentifully on a poor than on a rich cheese. Cold moist weather encourages it; but in warm weather, the oily exudation of a rich and well-made cheese goes near of itself to eradicate the white, and bring on that desirable blue coat, which is at once a criterion of the goodness of the cheese and of the skillfulness of the dairy-woman.

"The Norfolk dairy-woman, however, pays little regard to appearances; and, to speak truly of her, is equally ambitious to please the eye and the palate. Her method is this: the cheese (or rather as yet a bundle of curd) being taken out of the press, is salted upon a large earthen platter, in the same manner a piece of beef or pork is salted; and, having lain some time in salt, it is put upon a shelf to dry and stiffen.

"Being in a manner unpressed; never cleaned; and but seldom turned; it is no wonder, that in a short time the white scurfy coat gets full possession of it; or that its surface should appear bloated and wrinkled; or that its rind should be divided by innumerable fissures; or that its appearance, altogether, should be that of a sugared plumb-cake, rather than of a cheese.

"However, with respect to appearances, the Norfolk dairy-woman may plead in excuse that her customers are familiarized to the sights which she prepares for them: but when she follows a practice which subjects her produce, if not sold off while yet in an unripe state, to almost inevitable destruction, she is highly culpable.

"Cheeses made in this country are attacked by an enemy little dreaded, or wholly unknown, in the cheese counties; namely, a species of maggot, whose unlimited mischievousness seems to be confined to this part of the kingdom.

"The fly, which is the cause of this serious mischief, is of a species somewhat small, slender, black, and shining; very much resembling the small winged ant. Wherever it finds a crack or other defect in the rind, be it ever so minute, it turns its tail towards the aperture; and, by the insertion of a slender sheath not unlike the sting of a bee, there deposits its eggs. If the fissure be sufficiently large and deep, it enters its hind-parts also: if still deeper, it crawls backward into the cheese; leaving only its head in sight, and thus injects its eggs to a considerable depth.

"As the maggots rise into life, they travel still farther into the substance of the cheese; and, if it happens to be porous, soon pervade every part of it; in a few weeks working its total destruction: for not only the parts they immediately inhabit, but the whole cheese becomes bitter, and entirely inedible; except by some of the good people of the country, to whom custom has rendered even the maggots grateful.

"The first week or ten days, the new-made cheeses are carefully turned once a day; great care being had not to break the yet tender rind in turning; nor to suffer it to be cracked by too free an admission of a dry, parching air.

"As soon as they are become firm enough to be handled with safety, they are cleaned in this manner: some skimmed whey being put into a milk-lead, or other broad, shallow vessel, so as to cover the bottom of it half an inch or an inch deep, the cheeses to be cleaned are taken from the shelf and placed in the whey. One side being thoroughly moistened, the other side is placed downward: the edges too are wetted with a cloth, so as to make the whole coat of the cheese soaking wet. The dairy-woman then takes a hard brush, and brushes every part of the cheese; frequently dipping her brush in the whey, to eradicate the white coat more readily and more effectually. This done, she places them again on the shelves; but before they be quite dry, while their coats are yet moist, she rubs them over with a cloth, on which a piece of whey, or other common, butter has been spread. This keeps the rind supple, and free from cracks; checks the scurfy coat from rising; and, by stopping the pores and fissures of the coat, prevents the fly from depositing her eggs. If the rind be rough, from the marks of the cloth or other cause, she scrapes them

with a knife, or other instrument: this last operation, however, is as yet performed with great care and delicacy.

"Having thus washed and scraped them two or three times (in the course of about a week from the first cleaning) she removes them from the dairy-shelves into some spacious airy room, with a firm even floor, which she first rubs plentifully with green succulent nettles, so as to give it a temporary greenness, and then places her cheeses in rows upon the prepared floor. She now washes them no more; but if the coat be yet rough, and the scurf continue to rise, she scrapes them more freely than before; and, as the rind gets harsh, softens it with butter; thus continuing to treat them, and still continuing to turn them once a day, until they acquire a rich golden polish, and the blue coat begin to shew itself.

"This crisis, namely, the appearance of the blue coat, is not altogether regulated by the age of the cheese, but depends on its quality and the state of the weather. Perhaps it may appear before the cheese be one, perhaps not until it be more than two, or even three months old; therefore, no certain number of cleanings can be fixed; these rules, however, may be observable: scrape and rub them, until they be perfectly smooth; mellow the rind with butter, whenever, for want of natural exudation, their coats get dry and harsh; thus continuing to keep them smooth, yellow, and glossy, until the blue coat begin to make its appearance, voluntarily; and then, but not before, begin to encourage the blue coat.

"This ingenious process is thus conducted: having rubbed the floor thoroughly with fresh nettles, the dairy-woman places such of the cheeses upon it as she judges to be ready for coating; and upon the top of each cheese puts three or four vine-leaves; or, for want of these, a cabbage-leaf. This, if the cheese be good, will in a day or two bring up the desired vestment: but an inferior cheese will take a longer time in coating; and as the leaves lose their greenness and succulence, she replaces them with fresh ones; and as she turns the cheeses, which is now done every second or third day she re-covers the upper sides with leaves; but wipes their edges hard with a clammy cloth; so that the edge, and a narrow ring round each side, ever retain the polished yellow hue.

"When the cheeses were properly coated, and their edges had got sufficiently firm, they were placed on edge in a cheese-rack, and, without further care, (except once a week moving them a little round, and now and then wiping their edges) there remained until the time they were sent to market.

"Cheese-racks save labour in turning, collect the cheese into a small compass, and put it out of the way of vermin. They may be variously constructed. The plate-rack, with four or five tier one above another, seems to be the best form. If the cheeses be nearly of one size, the rack should be made the same width at the top as the bottom: but if they be of different sizes, it ought to be made narrower at the top than at the bottom; and if they be of different thicknesses as well as of different diameters, the spaces for the respective cheeses should likewise be varied. A small rack may be slung with a rope and pulleys at each end; so as to be drawn up and lowered down at pleasure: but a large one is difficult to sling, in a common room, in that manner; it ought therefore to stand on legs about two feet high, with a broad base-board projecting over the legs, so as to prevent vermin from climbing up into the rack.

"If from one year's experience I might venture to dictate in the art of making cheese in Norfolk, it would be in this way:

"To make use of a clean well-flavoured rennet.

"To pursue the method now in use of separating the curd from the whey: for, although the method above described may be eligible on rich land (and is practised in the counties of Wiltshire, Gloucestershire, and Warwickshire); yet, on a leaner soil, it may be prudent to preserve as many of the butyraceous particles as possible in the curd, rather than to suffer them to escape from this, and pass through the whey into butter; provided cheeses of a sufficient texture to secure them from the attacks of the fly, can be produced by the method of separating the whey now in practice in Norfolk.

"It is, however, observable in this place, that, in point of neat profit, it is highly probable that the certain advantage arising from the butter would more than overbalance any probable advantage which the quality of the cheese would receive by retaining in the curd a part of this butter.

" To let the cheeses remain in the press until they have acquired a sufficient degree of firmness, and their rind such a degree of toughness, that they may, on being taken out of the press, be safely handled, without danger of cracking.

" To keep their coats supple and clean ; the first, to prevent, as much as possible, their cracking afterwards in turning ; and the latter, to discover with greater readiness, and to remedy with greater ease when discovered, any flaw which, through accidents or oversight may happen.

" If through accident or neglect the fly should be suffered to make an impression (which is easily discoverable by a dimple in the rind and its softness to the touch), cut out the part affected (perhaps not yet larger than a walnut), dust the wound with pepper, fill it up with butter, and close it with a piece of soft paper : thus forming an artificial rind, which will secure it from further injury, until it has acquired an age sufficient to recommend it to a purchaser.

" By these rules, I am of opinion, that cheese of a middle quality as to richness, and secure against the fly, might be produced in East Norfolk ; provided the present method of separating the whey, will give the cheeseling a sufficient degree of texture to be handled with safety.

" My doubts, respecting this matter, arise not more from the loose crumbly texture of Norfolk cheeses in general, than from the following practice ; which, likewise, strengthens my apprehensions of the richness of the cheese in question being lowered by the curd having been broken too finely in the whey.

" A gentlewoman, who lives in this neighbourhood, who pays a personal attention to her dairy, and whose abilities in matters of household are indisputable, says, that when she wishes to make a cheese of a superior degree of richness, for her own table, she takes the curd and whey out of the cheese-tub very gently, with a fleeting dish (before they have been any way disturbed) and puts them immediately into the vat ; upon which she places a broad hoop ; by means of which she is able to pile up a sufficient quantity of this whey curd to fill the vat when pressed. She then folds over the cloth, and lets the press down upon it, very gently and gradually ; so as to squeeze out the whey, and at the same time retain that rich milky liquor which is mixed among the curd, and which by much breaking before it be put into the vat, is lost among the whey. With care, she says, the whey may be drawn off quite green and clear ; leaving the buttery particles behind in the cheese. By this means, she says, she has made cheeses which have tasted as fat as Gloucestershire cheese : but adds, that great care is necessary in handling a cheeseling thus made ; for if it crack, no pressing will ever close it again.

" If not, I am certain, that by adhering closely throughout, to the practice above registered, a wholesome good cheese, palatable to men in general, and proof against the fly, may be made in East Norfolk, with a great degree of certainty."

These observations, this ingenious gentleman indulged the public with in the year 1787 ; and two years after, in his Rural Economy of Gloucestershire on the same subject, says, " The art of making Gloucestershire cheese was originally one of the principal objects which induced me to make choice of Gloucestershire as a station. Being convinced, that in the quality of cheese, although much depended upon soil and herbage, much is certainly due to management.

" Gloucestershire has long been celebrated for its excellency in this art ; and where shall we study an art with so much propriety, as in the place where it excels, having had sufficient experience to enable me to make accurate observations on the practices of others.

" The objects of my attention have been,

Quality of milk,	Management of the curd,
Colouring,	Management of the cheese,
Rennets,	Defects and excellencies.
Method of running,	

" The management of the Vales of Gloucester and Berkeley differ in one most material article ; the quality of the milk. In the Lower Vale, the milk is run neat from the cow (or nearly so). In the Upper Vale, it has been already said, the prevailing practice is to set the evening's meal for cream ; in the morning to skim it ; and then to add it to the new milk of the morning's meal. The cheese made from this mixture is termed two-meal cheese : that from the neat milk, one-meal cheese or best-making.

" Besides this difference in produce, or species of cheese, there are other differences in the practices of the two Vales. It

will therefore be proper to register them separately ; left by mixing them, the perspicuity, which is requisite in describing the minutiae of an art so complex and difficult as this under consideration, should be destroyed.

" Of the Upper Vale the subjects to be noticed in this place are,

The season of making,
The quality of the milk,
Colouring,
Rennets,
Running,
Management of the curd,
Management of the cheese.

" The season of making, from the beginning of May to the latter end of October, including seven months, may be considered as the season of cheese-making, in this district.

" The mixture for two-meal cheese has been mentioned, in general terms, to be one part skim milk (namely milk which has stood one meal for cream) and one part new milk, neat from the cow. But this is seldom, I apprehend, strictly the case. A little fraud is, I am afraid, generally practised. A greater or less proportion of the morning's meal is set for cream, and returned the next morning to the cheese cowl, robbed of its better part. This is a trick played upon the cheese factor : but he being aware of the practice, little advantage, probably, is got by it. However, where the soil is superiorly rich, a small proportion may be kept out, and the cheese, nevertheless, be of a fair quality.

" Colouring is another deception which has long been practised by the Gloucestershire dairy-women ; and which, heretofore, probably, they practised exclusively. The colouring of cheese, however, is now become a practice in other districts.

" The practice has no doubt arisen from the Gloucestershire dairy-women's having observed, that, on some soils, and in some seasons, cheese naturally acquires a yellow colour ; and such cheese having been found to bear a better price, (either from its intrinsic quality, or because it pleased the eye better) than cheese of a paler colour, they set about counterfeiting nature ; and in the outset, no doubt, found their end in it.

" There is some difficulty, however, in this as in other cases, to copy nature exactly. Much depends on the material ; and something on the method of using it. If the colouring material be improperly chosen, or injudiciously used, the colour appears in streaks, and instead of pleasing the eye, offends it. On the contrary, with a suitable material, properly used, the artifice may be rendered undetectable.

" The material which has at length obtained universal esteem ; and which, I believe, is now almost invariably used, is a preparation of annotta ; a drug, the produce of Spanish America. It is brought to England (for the use of the dyers principally, I believe) under the appearance of an earthy clay-like substance ; but is well known to be a vegetable production.

" Annotta is the produce of *bixa orellana* of Linnæus. Miller describes the plant and its propagation. It is a tallish shrub, somewhat resembling the lilac : the colouring material is the pulp of the fruit, among which the seeds are bedded in a manner somewhat similar to those of the rose, in the pulp of the hip. It is a native of the West-Indies, and the warmer parts of America.

" Rennets are here learnedly spoke of by those who are superficially acquainted with their use. Experienced dairy-women, however, speak modestly on the subject : what they principally expect from rennet is the coagulation of their milk, having little faith in its being able to correct any evil quality which the milk may be possessed of.

" The universal basis is the stomach of a calf ; provincially a vell, from which an extract is drawn, in various ways, according to the judgment or belief of the dairy-women.

" The preparation of the vell, namely the cleansing and pickling, is generally done to their hands. Besides the internal supply, London and Ireland furnish this country with great numbers of vells, which are brought in casks, in pickle, and sold by the grocers and other shopkeepers. The price of English vells is about sixpence a piece, of Irish about fourpence ; these being comparatively small.

" In the dairy which I more particularly attended to in the Upper Vale, the rennet underwent no established mode of preparation. The prevailing method is this : some whey, being salted until it will bear an egg, is suffered to stand all night to purge itself : in the morning it is skimmed and racked off clear : to this is added an equal quantity of water-

ter-brine, and into this briney mixture is put some sweet briar, thyme, hyssop, or other sweet herbs; also a little black pepper, salt-petre, &c. tying the herbs in bunches, and letting them remain in the brine a few days. Into about six quarts of this liquor, four English vells, or a proportionate number of Irish ones, are put; and having lain in it three or four days, the rennet is fit for use. No part of the preparation is boiled, or even heated; and frequently no other preparation whatever is used, than that of steeping the vells in cold salt and water. Indeed, in another dairy, which I had an opportunity of observing in the Upper Vale, no other mode of preparation was used; and few if any dairies make better cheese: I speak from my own knowledge.

"Therefore, from the evidence which I have collected in the Upper Vale it appears that, provided the vells be duly prepared, be thoroughly cleansed and cured, no subsequent preparation of rennet is necessary. Nevertheless, were I to recommend a practice in this case, it would be that of doing away the natural faint flavour of the vells, by some aromatic-infusion: but I should prefer spices to herbs for this purpose.

"In this, as in every other stage and department of cheese-making, there are shades of difference, in the practices of different dairy-women. No two conduct the business exactly alike; nor is the practice of any individual uniform. There are at present, no fixed principles to go by. Every thing is left to the decision of the senses; uncertain guides. Nevertheless practice, carried on with attention, and assisted by good natural abilities, will do much; though it cannot alone attain that degree of perfection, which, when joined with science, it is capable of reaching.

"The mistress of the dairy, whose practice I am more particularly registering, has both natural and acquired advantages, which render her dairy, though not of the first magnitude, a proper subject of study. Her father was possessed of the best breed of cows in the Vale, and was one of the largest dairy farmers in it. Her mother, the first among its dairy-women, and herself possessed of that natural cleverness, without which no woman, let her education be what it may, can conduct, with any degree of superiority, the business of a cheese-dairy.

"In giving a detail of my own practice of Norfolk, I mentioned some known principles of coagulation, as well as some received opinions of dairy-women, respecting the nature of this process. The same opinions are held in this district, in which some other received ideas prevail: namely, that the quantity of curd is in proportion to the length of time of coagulation; there being the least curd when longest in coming.

"That setting the milk hot, inclines the cheese to heave: (a defect which will be spoken to hereafter.)

"And that lowering the heat of the milk with cold water (when made too hot) has a similar effect.

"To give some idea of the practice of the Upper Vale, in this most delicate stage of the art, I will detail the observations made, during five successive mornings, in the dairy which has been spoken of.

"Tuesday, 2 September, 1783. The quality of the milk, that which has been described. Part of the skimmed milk added cold; part warmed in a kettle over the fire, to raise the whole to a due degree of heat, coloured in the manner described; an estimated sufficiency of rennet added; the whole stirred and mixed evenly together; the exact heat of the mixture 85° of Fahrenheit's thermometer; the morning close and warm, with some thunder; the cheese-cowl covered, but placed near an open door; the curd nevertheless came in less than forty minutes, much sooner than expected, owing probably to the peculiar state of the air. The retained heat of the curd and whey, when broken up and mixed evenly together, 82° . The curd deemed too tough and hard, though much the tenderest curd I have observed.

"Wednesday, 3 September. The morning moderately cool; the heat of the milk when set $83\frac{1}{2}^{\circ}$. The cowl partially covered, and exposed to the outward air as before, came in an hour and a quarter; the heat of the curd and whey mixed evenly together 80° ; but at the top, before mixing, only 77° ; the curd extremely delicate, and esteemed of a good quality.

"Thursday, 4 September. The morning cool, a slight frost; the milk heated this morning to 88° ; the cowl more closely covered, and the door shut part of the time; set at half past six; began to come at half after seven; but not

sufficiently hard to be broken up until eight o'clock—an hour and a half. The whey, when mixed, exactly 80° . The curd exceedingly delicate.

"Thus it should seem, that it is not the heat of the milk when it is run; but the heat of the whey, when the curd is sufficiently coagulated, which gives the quality of the curd. My own practice led me to the same idea; and the Gloucestershire dairywomen, by their practice, seem fully aware of the fact. As autumn advances, the heat of the milk is increased; and accordingly as the given morning happens to be warm and cool, the degree of warmth of the milk is varied.

"Friday, 5 September. This morning, though mild, the curd came exactly at 80° ! what an accuracy of judgment here appears to be displayed! Let the state of the air be what it will, we find the heat of the whey, when the curd is sufficiently coagulated, exactly 80° , and this, without the assistance of a thermometer, or any other artificial help; but what will not daily practice, natural good sense, and minute attention accomplish.

"Saturday, 6 September. This morning the curd came too quick; the heat of the whey (after the curd had been broken and was settled) full 85° ! The curd much tougher and harder than it should be. Here we have a proof of the inaccuracy of the senses, and of the insufficiency of the natural judgment in the art under consideration: it may frequently prove to be right; but never can be certain. Some scientific helps are evidently necessary to uniform success.

"The management of the curd has five distinct operations belonging to it: breaking, gathering, scalding, vatting, preserving spare curd.

"In breaking, new ideas pour in. The curd, while suspended in the whey, is never touched with the hands. The curd is broken, or rather cut, with the triple cheese-knife, which has been described. This mode of separating the curd and whey, though not universal, appears to be highly eligible: the intention of it is that of keeping the fat in the cheese: a matter which, in the manufacture of two-meal cheese, is of the first consideration. The operation is performed in this manner:

"The knife is first drawn its full depth across the cowl in two or three places; and likewise round by the sides; in order to give the whey an opportunity of escaping as clear as may be. Having stood five or ten minutes, the knife is more freely used: drawing it briskly in every direction, until the upper part of the curd be cut into small checquers. The bottom is then stirred up with the dish, in the left hand; and, while the lumps are suspended in the whey, they are cut with the knife in the right; thus continuing to stir up the curd with the dish, and separate the lumps with the knife, until not a lump larger than a bean is seen to rise to the surface.

"The curd having been allowed about half an hour to settle in, the whey is laded off with the dish, passing it through a hair sieve into some other vessel.

"The principal part of the whey being laded off, the curd is drawn to one side of the cowl, and pressed hard with the bottom of the dish; the skirts and edges cut off with a common knife, and the cuttings laid upon the principal mass, which is carried round the tub, among the remaining whey, to gather up the scattered fragments that lie among it. The whole being collected, the whey is all laded or poured off, and the curd left in one mass, at the bottom of the cowl.

"It is, I believe, the invariable practice of the dairywomen of Gloucestershire to scald the curd. This accounts for their running the milk so comparatively cool. Were the delicate cool-run curd of this district to be made into cheese without previously scalding, the cheese made from it would require an inconvenient length of time to fit them for market.

"The method of scalding the curd here varies from that mentioned in the Economy of Norfolk. There it was scalded in the mass, pouring hot water over the surface, as it lay at the bottom of the cheese-tub: but here the mass is broken, first by cutting it into square pieces with a common knife, and then reducing it, with the triple knife, into small fragments, mostly as small as pease: none of them is left larger than a walnut; and among these fragments the scalding stuff is thrown, stirring them briskly about, thereby effectually mixing them together; and, of course, scalding the whole as effectually and as evenly as this method of scalding will admit of.

"The

"The liquid made use of here, for scalding curd, varies in different dairies. Some dairywomen scald with whey, violently objecting to water, while others use water, objecting with equal obstinacy to whey, while dairy-women in general, I believe, mix the two together.

"It seems to be understood, that different grounds require different kinds of scalding liquor.

"The quantity is in proportion to the quantity of curd; enough to float the curd, and make the mixture easy to be stirred about with the dish.

"Part of it is heated to near boiling heat, and this lowered with cold liquid to a heat proportioned to the state of the curd: soft curd is scalded with hot, hard curd with cooler liquid.

"In scalding, therefore, the dairy-woman has a remedy for any misjudgment her sense of feeling may have led her into, in the stage of coagulation: let the curd come too soft or too hard, she can bring it to the desired texture, by the heat of the scalding liquid. And here seems to hinge, principally, the superior skill of the Gloucestershire dairy-woman: by running the milk cool, she can, in scalding, correct any error which has been committed in running.

"Saturday, 6 September. This morning, the curd being too tough, the whey was used cooler than it was yesterday morning, when the curd was sufficiently tender. Yesterday morning 140°, this morning 125°.

"Tuesday, 9 September. This morning the curd came at its proper heat 80°, and the heat of the scalding whey was 142°.

"The curd being thoroughly mixed and agitated among the whey, and having had a few minutes to subside in, the dairy-maid began immediately to lade off the whey. This, however, is not the universal practice: in some dairies the curd is suffered to remain among the scalding stuff half an hour: thus (as has been observed) there are shades of difference in every stage of the process.

"Wednesday, 24 Sept. This morning the curd came too tender, and the morning being cool, the scalding whey was heated to 161°, and stood upon the curd near ten minutes: this changed it from a state of jelly as to softness, to the same tough hard mass it is always left after scalding.

"The scalding liquor being mostly laded off, a vat is placed on the cheese-ladder, laid across the tub, and the curd crumbled into it with the hands, scrupulously breaking every lump, squeezing out the whey as the handfuls are taken up, and again pressing it with the hands in the vat, which is every now-and-then set on edge to let the whey run off.

"The vat being filled as full and firmly as the hand alone can fill it, and rounded up high in the middle, a cheese cloth is spread over it, and the curd turned out of the vat into the cloth; the vat washed or rather dipped in the whey, and the inverted mass of curd with the cloth under it, returned into the vat. The angles, formed by the bottom of the vat, are pared off and crumbled upon the top, with which they are incorporated by partially breaking the surface, and rounded up in the middle as before; the cloth folded over and tucked in; and the vat with its contents placed in the press.

"It is observable that only one cheeseboard is used in the Gloucestershire dairies, let the number of vats be what they may. The bottoms of the vats being made smooth and even, they answer the purpose of cheeseboards to each other, the uppermost only requiring a board. No sinking boards are ever made use of here, as they are in other districts, the vats being rounded up with curd in such a manner as, from experience it is known, will just fill them when sufficiently pressed.

"Preserving the overflowings of the last vat of to-day's curd, to be mixed up with that of to-morrow, is a common practice of this country, where cheeses, if they be intended for the factors, are obliged to be made of some certain size. The vats are all nearly of the same bigness, and cannot be proportioned to the curd, as they may when vats of various sizes are made use of.

"In the neighbourhood of Gloucester, when the quantity of spare curd is considerable, as four or five pounds, it is frequently made into a small cheese for the Gloucester market, in which it may be sold, in a recent state, (namely at three weeks to two months old) from 2½ to 3½ a pound, according to its age: three pence a pound is the ordinary price for such little two-meal cheeses.

"When the quantity of spare curd is small, or where the making of the little cheeses is not practised, the whey is pressed out and drained off as dry as may be, and the curd

preserved in different ways. In the Upper Vale I have seen it put into an earthen vessel and covered with cold water. The next morning it is re-scalded thoroughly once or twice; broken as fine as possible, and either mixed evenly with the fresh curd; or, less eligibly, put into the middle of a cheese: This, however, is, with good reason, objected to by the factors. A harsh, crumbly, ill tasted seam is formed in the middle of the cheese; a disagreeable circumstance, which, in cutting a cheese, is too frequently met with. Mixing the stale curd more evenly among the fresh has an effect almost equally disagreeable: the particles of the stale curd ripen faster than the rest of the cheese, which is thereby rendered unsightly and ill-flavoured.

"In a small dairy it is impossible to make cheeses sufficiently sizable for the Gloucestershire factors, and at the same time avoid having, frequently, spare curd. But in a large dairy, where three or four cheeses are made from one running, it might, by a proper number and assortment of vats, be generally avoided, and the cheeses be at the same time made within size.

"The management of the cheeses requires to be subdivided agreeably to the different stages of management:

"The management in the press. The management while on the dairy shelves. The operation of cleaning. The management in the cheese-chamber.

"Having stood some two or three hours in the press, the vat is taken out; the cloth pulled off and washed, the cheeseling turned into the same cloth and the same vat, (the cloth being spread under and folded over as before) and replaced in the press.

"In the evening, at five or six o'clock, it is taken out of the press again, and salted in this manner: the angles being pared off, if wanted, the cheeseling is placed on the inverted vat, and a handful of salt rubbed hard round its edge, leaving as much hanging to it as will stick. Another handful is strewn on the upper side, and rubbed over it pretty hard, leaving as much upon the top as will hang on in turning. It is now turned into the bare vat, without a cloth; and, a similar quantity of salt being rubbed on the other side, is again put into the press.

"Next morning it is turned in the bare vat; in the evening the same; and the succeeding morning taken finally out of the press, and placed upon the dairy-shelf.

"Each cheese therefore stands forty-eight hours in the press. At the second or third it is turned in the cloth; at the tenth, the cloth is taken off and the cheeseling salted; at the twenty-fourth, it is turned in the bare vat; at the thirty-fourth, the same; and at the forty eighth finally taken out.

"The method of making green cheese, in this district, is the following: For a cheese of ten or twelve pounds weight, about two handfuls of sage and one of marigold leaves and parsley, are bruised and steeped one night in milk. Next morning the greened milk is strained off, and mixed with about one third of the whole quantity to be run. The green and the white milks are then run separately, keeping the two curds apart until they be ready for vatting. The method of mixing them depends on the fancy of the maker. Some crumble the two together, mixing them evenly and intimately; others break the green curd into irregular fragments, or cut it out in regular figures with tins for this purpose. In vatting it the fragments or figures are placed on the outsides. The bottom of the vat is first set with them, crumbling the white or yellowed curd among them. As the vat fills, others are placed at the edges, and the remainder buried flush with the top. The after-treatment is the same as that of plain cheeses.

"In the management on the dairy-shelves, the young cheeses are turned every day, or every two or three days, according to the state of the weather, or the fancy or judgment of the dairywomen. If the air be harsh and dry, the window and door are kept shut as much as may be: if close and moist, as much fresh air as possible is admitted.

"Having remained about ten days in the dairy (more or less according to the space of time between the washings,) they are cleaned, that is, washed and scraped, in this manner: a large tub of cold whey being placed on the dairy floor, the cheeses are taken from the shelves and immersed in it, letting them lie perhaps an hour or longer, until the rind become sufficiently supple. They are then taken out, one by one, and scraped with a common case-knife somewhat blunt, guiding it judiciously with the thumb placed hard against its side, to prevent its injuring the yet tender rind;

rind; continuing to use it, on every side, until the cloth marks and every other roughness be done away; the edges more particularly being left with a polished neatness. Having been rinsed in the whey and wiped with a cloth, they are formed into an open pile (in the manner raw bricks are usually piled) in the dairy window, or other airy place; to dry, and from thence are removed into the cheese chamber.

"The floor of the cheese chamber is generally prepared, by rubbing it with bean-tops, potatoe-haulm, or other green succulent herbage, until it appear of a black wet colour. If any dirt or roughness appear upon the boards, it is scraped off with a knife, and the floor swept clean with a hair broom. The cheeses are then placed upon it regularly in rows; and kept turned twice a week, their edges wiped hard with a cloth once a week, and the floor cleaned, and rubbed with fresh herbs once a fortnight.

"The preparation of the floor is done with the intention of encouraging the blue coat to rise. To the same intent the cheeses are not turned too frequently; for the longer they lie on one side without turning, the sooner the blue coat will rise. If, however, they be suffered to lie too long without turning, they are liable to stick to the floor, and thereby receive injury. If, by accident or otherwise, the coat come partially, it is scraped off. This however seldom happens in a rich-soiled country, and all the care and labour requisite, in this stage, is to turn them twice a week, wipe their edges once a week, and to prepare the floor afresh once a fortnight. If the cheese chamber be too small to admit of the whole being placed singly, the oldest are doubled; sometimes put three or four double.

"It is striking to see how well cheeses of this district bear handling at an early age: even at the time of washing, the dairymaid will frequently set the cheese she is scraping on-edge upon another, lying flat on the table, without injury. At a month old they may be thrown about as old cheeses. Their rinds appear as tough as leather. This must be owing to the scalding: it cannot be owing to their poverty. They are evidently richer, fatter, than the new milk cheeses of many districts.

"In large dairies in the Upper Vale, cheese is sold and delivered three times a year, namely in July; again at Michaelmas, and finally in the spring. In small dairies only twice: about the latter end of September, and again in the spring.

"It is bought principally by cheese factors, who live in or near the district. The same factor generally has the same dairy, year after year, frequently without seeing it, and, perhaps, without any bargain having been made previous to its being sent in. There is, indeed, a degree of confidence on the part of the buyer and seller, which we seldom meet with among country dealers.

"In summer and early autumn the factors will take them down to six weeks old, provided they be found firm marketable cheeses; that is, neither broken nor hove: a defect which even the best dairywomen cannot always prevent. During winter, provided their coats be perforated to give the internal air an opportunity of escaping, the swollen cheeses will generally go down, and, in the spring, become marketable.

"Mr. Marshall, having treated of the Vale of Gloucester, thus proceeds with the Vale of Berkeley, in which he says "It will be proper to remark; that the hundred of Berkeley, which forms a considerable part of that district, has ever been celebrated for the superior quality of its cheese. What in the kingdom at large is termed Gloucester cheese, particularly double Gloucester, is in Gloucestershire called Double Berkeley: not more on account of the superior quality of the cheese of this district, than because the principal part of the thick cheese of Gloucestershire is made within this hundred.

"It will likewise be proper to apprise the reader, that the cheese of this district was in higher repute some fifteen or twenty years ago than it is at present; as otherwise some expressions which occur would be obscure. It must, however, be understood that there is no cheese of the first quality now made in the Vale of Berkeley: all that is meant to be conveyed is, that the cheese of Berkeley hundred is not so uniformly excellent as it was some fifteen or twenty years ago.

"In this case, as in that of the Vale of Gloucester, on the same subject, it will be proper, before the objects be separately examined, to take a view of

Managers, Utensils,
Dairy-rooms, Milking.

"The three last, however, vary so little from the description already given of those of the Upper Vale; that it is unnecessary to repeat the descriptions here. Therefore the only thing requisite, in this case, previous to an account of the particular objects; is some account of the managers of the Lower Vale; especially those from whom I gained my information, and whose practice I am about to register.

"A superior dairywoman is so highly spoken of, and so highly valued, in this district, that one is led to imagine every thing depends upon management. Instances are mentioned of the same farm, under different managers, having produced good and bad cheese: even changing a dairy-maid has been observed to make a considerable difference in the quality of the produce.

"On the other hand it has likewise been frequently seen that the same managers, the same dairy-woman, the same assistants; and the same cows, which on one farm produced cheese of the first quality, have not, on being transferred to another, been able, on their first removal (at least) to produce marketable cheese. Indeed it seems to be generally understood throughout the two Vales that it is necessary to know the ground, by two or three years experience, before good cheese can be made with any degree of certainty.

"These two circumstances tend to prove the same fact: namely, that very much depends upon management.

"I had an opportunity of seeing different dairies in the Vale of Berkeley, and of observing the practices of different dairywomen; but the dairy which principally engaged my attention was that of Maherley, near Berkeley, whose manager, Mrs. Wade; whether we consider her education, her natural abilities, or her experience, ranks, most deservedly, among the first dairywomen of the district. Her mother was mistress of an hundred cows; herself of forty or fifty, during the last twenty or thirty years. What renders her practice singularly valuable, is that of its being the old established practice, which brought the Berkeley cheese to its highest degree of excellency, unaltered; as that of most dairies has been, by modern deviations.

"From this I was led to a modern dairy, equally distinguishable, that of Mr. Bigland of Frocester, the man most capable of giving me information, in every department of the subject I was investigating. As purchaser of, perhaps, half the cheese which is made in the Vale of Berkeley, he is, of course, intimately versed in the quality of cheese. As proprietor of a dairy of more than fifty cows, the business of a dairy farm is familiar to him. And, as a man of science; he has paid more attention to the minutiae of the art, most especially under consideration, than any other man I have conversed with on the subject. His ability of information, however, was exceeded by his liberality in communicating it. He not only gave me free admittance into his dairy, but led me over his warehouses, and, in the most disinterested manner, made me acquainted with the good and bad qualities of cheeses; of the defects they are liable to, and the excellency they are capable of.

"The objects of the dairy of this district are, in species, the same as those of the Upper Vale: namely,
Calves, Milk, Butter, Cheese:

"In the management of the two first, I met with nothing new or noticeable. The quantity of milk-butter made here in summer is small. Every pound is plunder. Cheese-making was the object which led me into the district, and was the almost only subject which engaged my attention.

"The species of cheese is, in respect to quality, uniformly new milk, one meal, best making; but in regard to size the species varies. It is either double or single, thick or thin. The thin cheeses, when marketable, weigh from nine to twelve pounds each; the thick from fifteen to twenty-five pounds. The width of the vats is for both species the same, namely about fifteen inches, the size being varied altogether by thickness.

"The requisite subdivisions of the subject, in this case, are the same as in the Upper Vale.

"The season of making thin cheese, is from April to November; but the principal season for making thick cheeses is during the months of May, June, and the beginning of July. If made late in the summer, they do not acquire a sufficient degree of firmness, to be marketable the ensuing spring.

"Here, as in the Upper Vale, the milk is seldom genuine; it being, I believe, an universal custom to keep a little out. The practice has two conveniences attending it; it brings in a little easy-got ready-money to go to market with, (while

(while the trades-people in return are furnished with better butter than otherwise they might have) and the skimmed milk is found useful in lowering the too great warmth of milk immediately from the cow. If the proportion skimmed be not great, the crime committed is venial, the milk of this country being much above par as to richness: even lowered as it is, the cheeses made from it will sometimes, in hot weather, exude an oleaginous liquid which might be collected in spoonfuls from their surfaces.

"Colouring is here considered as a thing of the first importance in the art of cheese-making. A good material is highly valued, but is not always to be easily come at by dairy-women, who, perhaps, have only one market to go to. For this reason it is here a pretty general practice for the cheese-factor to furnish the dairies, whose cheeses he expects to purchase, with colouring of the best quality.

"Thus we find the crime of colouring cheese is not an act of darkness, done clandestinely by the dairywoman, to deceive the factor; but, on the contrary, an open, known department in the business of cheese-making, to which the factor gives his assent and his assistance. The dairy-woman's motive is evidently that of obliging her customer the factor. Should it be asked what can be the factor's motive for encouraging this adulteration of an article of human food, the answer is evident: he can have no other than that of obliging his customers, the cheesemongers, who as evidently encourage this abominable practice, for the base end of obliging their customers, the consumers. The truth is, men in general prefer well-coloured cheese to that which is ill coloured; or, in other words, highly-coloured cheese is at present fashionable. The cheesemongers knowing this, will not purchase pale coloured cheese of the factors; and, for this reason, the factors object to a pale-coloured dairy of cheese.

"In the infancy of the art, the colouring of cheese was a crime, because it was then done with an intent to deceive: but dairy-women, at present, have no such intention. They colour it now, through a kind of necessity, and with intentions as innocent as those of other manufactures who change the colour of their raw materials. If the eaters of cheese were to take it into their heads to prefer black, blue, or red cheese, to that of a golden hue, I will venture to pass my word for the dairywomen, they would do their best endeavour to gratify them.

"If, in the colouring of cheese, any pernicious substance be made use of, the consequences to the community may be of a serious nature: but whether the preparation of annotta, which is now in common use for that purpose, be pernicious or salubrious to the human frame, no man perhaps has ever attempted to ascertain: it may, for any thing the declaimers against it appear to know to the contrary, be the most salutary alterative human invention can devise. It may, however, be destructive to human health, and its medical qualities ought certainly to be enquired into.

"It is, no doubt, a fact, that annotta belongs to a class of plants, many individuals of which are of a poisonous nature. The fastidious, however, have less to fear, since the celebrated *thea* (tea) stands not only in the same class, but in the same order, with *bixa orellana*.

"It appears by observations sufficiently accurate, that one ounce avoirdupoise of this preparation will colour, sufficiently, more than two hundred pounds of cheese. The number of grains in one ounce avoirdupoise are 437½. So that each pound of cheese, moderately coloured, contains two grains of the preparation.

"Few men, perhaps, eat more than a pound of cheese a day each (I speak of men whose principal food is cheese). It ought without dispute to be enquired into, whether two grains of that preparation, taken daily, is or is not injurious to the human frame. As to the small quantity which is eaten by men in general, on a stomach already cloyed with other aliment, it does not seem to be an object of enquiry. If so inconsiderable a portion were capable of doing any degree of injury, thousands must long ago have been poisoned by eating cheese. It might, nevertheless, be well, both for the manufacturers and the consumers of cheese, if some regulation could be made respecting the material of colouring.

"The prudent manager of the Maberley dairy cures her own vells, under a conviction, resulting from long experience, that more depends on the vell itself, than on any particular method of preparing rennet from it.

"Her method of preparing the vells is the same as given before. Being first made perfectly clean by washing, they

are salted and laid down, in an earthen vessel, for a few days. They are then taken out, the first pickle drained from them, re-salted, and put down into jars. She seldom uses them under one year old: she sometimes keeps them two or three years before she uses them.

"Her ordinary method of preparing her rennet is to lay the vells in salt and water, which has been boiled with a little black pepper in it, and to add a lemon stuck with cloves, which (the lemon) she thinks gives the rennet a quickness; but says, that she has put the vell into a little cold water, and made as good a cheese from it as ever she did with prepared rennet. She never uses the vells a second time.

"The rennet made use of at Frocester was prepared in this manner: to two gallons of water, made salt enough to bear an egg, add one pennyworth of mace, one pennyworth of cloves, a handful of sweet briar and hawthorn buds, a small quantity of alum (about the bulk of a small walnut) the same quantity of sal prunellæ, a small quantity of cochineal, (a small pinch, the bulk of half a hazle nut) and, if to be had, two or three bay leaves. Pound the alum, salt prunel, &c. and having mixed the several ingredients with the salt and water, add five vells; or, if small, six or seven. In about ten days the rennet will be fit for use.

"Another recipe which I was favoured with in this Vale is the following: three handfuls of common salt to three quarts of water: a quarter of an ounce of salt petre, as much black pepper as will lie upon a shilling, a small quantity of agrimony, a sprig of sweet-scented thyme, a handful of sweet briar, a handful of the red buds of hawthorn, four heads of sage. Add the ingredients, and boil the water a quarter of an hour. To the liquor, when cold, put one vell. The rennet may be used the next day.

"I mention the different methods of preparing rennet, because they, in reality, form a part of the practice I am registering. They are facts which ought not to be omitted. Nevertheless, from what I have been able to learn from men who have an opportunity of observing the effects of different rennets, their efficacy reaches no farther than to do away the faintness of the vells, and thereby render the rennet perfectly sweet.

"It is well understood that the quality of curd varies with the degree of heat of the milk at the time of coagulation. Milk immediately from the cow, especially in summer, is, in this district, considered as being much too warm for running, requiring to be lowered to a desired degree of heat, before the rennet be added. If the skim milk of the preceding meal be not adequate to this intention, cold water is added, to reduce it to the required heat; and no evil effect is perceived from the practice. In my own experience, cold water had, in this case, a probable bad effect.

"In the Upper Vale I found the use of it, for this purpose, cautiously avoided. Nevertheless, in this Vale, there are dairy-women of the first character, who will throw a pailful of cold water among their milk, without being apprehensive of any evil effect. It is highly probable that much depends on the specific quality of the water used for this purpose. The water of the Upper Vale is not of the best quality. The waters of Cheltenham, or those of Harrogate, might have a still worse effect.

"Maberley, 4 Oct. 1783, half past seven in the morning. Heat of the air in the dairy-room 58°, of the milk when stirred up with the rennet 86°; covered with cheese-cloths, came at half past eight, one hour, at 84°. the curd untender.

"Note—the small loss of heat in this instance is probably owing to the quantity of milk and the closeness of the morning.

"Maberley, 4 Oct. 1783. Half past four in the afternoon. The air 64°, the milk 84°. came at half past five, one hour, at 81½°. The curd delicate.

"Frocester, 9 Oct. 1783. Twenty minutes before eight in the morning. Heat of the air in the room 53°. of the milk 81°. Covered first with cheese-cloths, and afterward with a thick woollen cloth. At a quarter before nine, the coagulation having then begun to take place, the surface was broken with a skimming-dish to hasten the coming: a practice not uncommon in this dairy, where the milk is run peculiarly cool. At nine the coagulation was complete, one hour and twenty minutes. The heat of the whey 76°. The curd extremely soft and delicate.

"Maberley, 4 Oct. 1783. Morning. The curd broken with a double cheese-knife, and also with the hand, keeping it in motion with the dish.

"In this dairy the cheese-tub is scarcely left from the time the curd comes, until it be gathered in a mass. As the curd settles, the dairywoman keeps collecting it, with her hands, to one side of the cowl, carrying the mass round the tub, from time to time, to collect the scattered curd the faster. The whey is laded off, into a large oval tub, to stand for cream. The curd being laid bare, the skirts of the mass are cut off and piled upon the rest; at the same time gathering the body of the mass, to let out the whey which may have been shut up in gathering. The remaining whey is strained through a sieve, to collect the crumbs of curd, of which the Gloucestershire dairywomen are scrupulously tenacious.

"The curd being thus freed from the principal part of the whey, but not yet from the whole of it, it is put into naked vats, (pressing it well in with the hands, rounding it up in the middle, in the usual way, throwing a loose cloth over, and tucking it in) and the vats set in the press, in order to free it the more effectually from the remaining whey.

"Having stood ten or fifteen minutes in the press, it is turned out of the vats into the cheese tub again, broken small with the hands, and cut still smaller with the double knife.

"It is now scalded with water lowered with whey, about three parts water to one part whey. The heat, in the instance under notice, 108° . The quantity a pailful, thrown upon the crumbled curd, and the whole stirred briskly about; mixing the curd and the scalded stuff evenly together. The heat of the mixture 84° .

"Having stood a few minutes for the curd to subside, the liquor is laded off, the curd collected, and vatted in this manner: an assistant takes the curd out of the tub, the manager trimming it into the vats, both of them pressing it hard with their hands, freeing it all they can from the scalding liquor.

"The vat about half full, a little salt, about an ounce, is scattered over the surface, and worked in among the curd, the vat filled up, and the mass turned two or three times in the vat, the edges being pared and the middle rounded up, each turning. At length it is turned into a cloth, in the manner which has been described in the Upper Vale, and placed in the press.

"Note.—In this instance one of the vats being found too full, and another not sufficiently, a thin slice was shaved off the one and laid upon the other, without any breaking or intermixture, to make the parts incorporate.

"Maberley, 4 Oct. 1783. Evening. The method of breaking, collecting, and freeing from the whey, the same as in the morning. The heat of the scalding liquor in this instance 106° , which was lowered by the curd to 90° , the quantity and quality nearly the same as in the morning.

"Note.—The quantity of curd being in this instance considerably less than it was in the former, the heat of the mixture became of course greater than it was in the morning. Here lies a delicacy of management: it is not the heat of the scalding liquid, but that of the mixture, which gives the texture of the curd; a circumstance this excellent dairywoman is fully aware of. She therefore keeps some of the hot liquor back, and having stirred the mixture, adds, or withholds it, as her judgment directs her, regulating the heat of the mixture to the state of the curd: thus she scalded 84° , with 84° — $81\frac{1}{2}^{\circ}$, with 90° .

"Frocester, 9 Oct. 1783. The curd broke with a double (one-edged) knife alone, without using the hand, immediately, in the operation; keeping it moving, as in the other instances, with the dish; the operation taking up about ten minutes.

"Having stood about twenty minutes to settle, the curd was collected with the dish, hands, and arms, to one side of the cowl; the whey laded off, the curd collected nearer together, pressed gently in the bottom of the cowl, and put into vats and the press, to free it from the remaining whey.

"Note.—Here we have a material difference in the practices of the two Vales: in the Upper Vale it is recommended to get the curd hard together with the hands in the bottom of the cowl; but subjecting it to the power of the press is a much higher kind of compression. There the curd is, through the species of milk, leaner than it is here, where a little fat is not missed; and thus squeezing the curd, while soft, may, perhaps, assist in freeing it from that superfluous richness which may promote its heaving.

"Having remained full twenty minutes in the press, the curd was returned into the cowl, cut small with the double

knife, and scalded with a pailful of hot water; lowered by a dash of whey, to 124° , which the curd reduced to 95° .

"Note.—The scalding liquor, in this instance, almost wholly water, became, after it had stood some time upon the curd, as rich to all appearance as whey: a yellow oil swimming on the surface.

"The cheese management in the press. Maberley;—having stood about an hour in the press, they are turned in finer cloths; and, about two hours afterward, salted the first time, and turned into the same cloths. The presses, which I saw in this Vale, were mostly loaded with gravel, in cubical boxes, raised by rollers, and made to fall horizontally on the cheeses. The Maberley press is double; each division of it holding six or eight thin cheeses. In very large dairies, especially where much thick cheese is made, three or even four presses are requisite.

"In the evening, those made in the morning are again turned, and again salted; and the same repeated next morning: the surface of each cheese being salted three times, besides the little strewed among the curd. The ensuing evening they are bare-vatted; and the next morning finally taken out: each cheese standing four meals in the press.

"The method of salting, in this dairy, varies from that which has been described. The cheese is salted in the vat. On taking it out of the press the cloth is thrown back and the upper side salted: the edges are then raised up with the cloth (one part after another) high enough above the rim of the vat to be conveniently salted: the cheese being turned, (in the same manner as it would be if the salting were not done) the other side is salted; the cloth spread over; and the vat returned to the press.

"Frocester;—the cheese having stood some five or ten minutes in the press, they are turned into dry cloths, of the same degree of fineness as those taken off. In these, they stand in the press, until the next meal; when they are salted the first time. The second meal they are again turned into the same cloth, and salted the second, which is the last time. The third meal the cloths are taken off; the cheeses being then put into the bare vats; in which they remain so long as there is room for them in the press; perhaps three or four days.

"I observed a different management of spare curd, here, to that described in the Vale of Gloucestershire management. Here I found it cut into slices, salted, and left spread upon an inverted vat, until the ensuing meal: when it was broken and mixt promiscuously with the fresh curd. But under this management (though kept only one meal) it is found injurious to the cheese; and is therefore to be avoided with all possible care.

"Where a large dairy of cows are kept, the dairy-room shelves are not sufficient to contain the young cheeses; which, in large dairies, are carried, immediately from the press, into an upper room, fitted up with shelves for their reception. Here they are turned, generally once a day; and remain under this treatment, until they have acquired a sufficient degree of texture, to enable them to undergo the operation of washing: a work which is gone through every three, four, or five weeks, as convenience, or want of room, may require.

"Cleaning is done, here, in a manner similar to that which is described in the Vale of Gloucester. In some dairies, water is used; not whey; and in autumn, when the weather gets cold, the water is moderately warmed. Hot water is thought to soften the rind too much, and is deemed improper.

"Note.—In the operation of washing, the firmness or solidity of the cheeses is seen in their specific gravity; by observing which of them sink and which of them swim in the water. If they sink, they are of a sufficiently close texture: if they swim, they are hove; that is, either porous, or hollow in the middle. This is a very simple, and it seems, a very certain ordeal.

"Cheeses rich in quality, and well manufactured; more especially, I believe, the produce of some particular soils; acquire, by age, a variegated colour; particularly at and near the surface; which becomes clouded with red. This natural effect is not unfrequently observable in Cheshire cheese: which being (until very lately) suffered to appear in its natural colours, the reddening parts show themselves evidently, through the paleness of the ground they appear in. I have also seen an instance of this effect in some Gloucestershire cheese, of a curiously fine quality, and great age.

"The exact time when the imitation of this natural effect took

took place, or by whom it was first practised, I have not been able to learn; with any degree of certainty; notwithstanding it is a late invention. Like the internal colouring, it probably originated in fraud. It was, perhaps, in the first practisers, an artful trick; an imposition on the purchaser. At present, however, it is practised through very different motives. The dairywomen, one and all, dislike it. The labour and expence of colouring they bestow with cheerfulness; but the act of painting, though done with less trouble and less expence, is set about with reluctance, and spoken of with disgust; especially by experienced dairywomen; who prefer the blue disk and the yellow edge to any artificial redness.

"At present, the painting of cheeses is practised merely as a characteristic. It is done at the request of the immediate purchasers; who cannot dispose of them (without being suspected at least of imposition) as Gloucestershire cheese, unless they bear its characteristic.

"Formerly, Gloucestershire cheese was known by the height of its internal colour. Colouring was then its characteristic. At length, however, the art of colouring began to travel into other districts; it is now become in a manner general; and colouring has not, for some years past, been characteristic of Gloucestershire cheese. The cheese of this district, however, has ever been, and probably will continue to be, in high esteem. Some evident mark, some specific character, is therefore required, by the dealer at least, to distinguish it, at sight, from that of other districts: and it may be a moot point whether the practice of painting originated in fraud; or whether it was first intended to be, what it really has been, a characteristic of Gloucestershire cheese. Be this as it may, it seems to be almost certain that it will not long be able to maintain its character; if it has not already lost it. The art of painting has begun to travel; and will, in all probability, soon become the general practice.

"Thus it appears, that the Gloucestershire dairy is suffering through its own artifice. Had it not first taught the art of colouring, its cheeses might still have been distinguishable, in their native colours, by the superior blueness of their sides, and the golden hue of their edges. It likewise appears evidently, that Gloucestershire is able to give the fashion to the colour of cheese. The Gloucestershire dairywomen have therefore, now, a fair opportunity of atoning for the sins of their ancestors; and of giving a characteristic to their cheeses, which cannot be universally counterfeited: namely its own natural colour. Could they muster courage enough to leave it to nature for one season only, the characteristic would be established, and the fashion for uncoloured cheese would be set. Other districts would in consequence follow the example; and the present filthy practices be got rid of, in a way more ready and more effectual, than by any compulsory means that could be made use of. If a certain noble earl would signify a wish that the cheeses produced upon his estate should appear in their natural colours; his tenants love his lordship too well, to suffer them to go to market in any other.

"The cheeses being cleaned, and afterwards disguised in a way unworthy of record,—they are taken to the cheese chamber; entering what I call the second stage. In some dairies, the floor is prepared with succulent herbage, in the manner which has been described; and in others it is only rubbed clean with a cloth. Cheeses bedizened in scarlet require not a blue coat: nevertheless, the succulency of the herbage is thought by some to keep the rind supple and free from cracks, and to kill or prevent mites. Nevertheless, as an actual operation in the present practice of Gloucestershire, it ought to be mentioned. The materials Spanish brown, and Indian red; sometimes mixed; sometimes used separately. The method varies: some dab on the colouring, wet, with a cloth; others, while the surface is moist, throw it on, dry, in pinches, irregularly; rubbing it in with the hand. The latter is allowed to be the more mistressly manner.

"In the cheese-chamber, they are turned twice or three times a week, and wiped with a cloth about once a fortnight; remaining in this stage until they are firm enough to set on-edge, or put into piles.

"From the cheese-chamber they are removed into other rooms; and placed in rows on-edge, or put into piles, of a height proportioned to their degrees of dryness. Here they remain until they are sent to market. If, in a large dairy, they do not go off regularly, at the accustomed

times, every room in the house, every upper room at least, will be full of cheeses.

"Three species of produce deserve notice:

"The produce of a given quantity of milk:

"The year's produce of a cow.

"The annual produce of the district.

"By a pretty accurate calculation, in the Upper Vale, I found that a cheese weighing somewhat more than 11 lb. (namely a ten to the cwt.) took about 15 gallons of milk (ale measure) or one gallon and one third to 11 lb. of two-meal cheese. From two instances, minuted with tolerable accuracy in this district, the proportion appears to be in one instance somewhat more, and in the other somewhat less than 11 lb. of curd to one gallon of new milk. These proportions, however, are offered merely to convey a general idea of the subject. The milk was gauged with a common rule, and the curd estimated by the vats: nevertheless, the calculations are sufficiently accurate for this intention.

"A dairy of 40 cows made, in October, about 60 lb. of cheese a day. But the cows were then going off their milk: suppose, that in summer they produced 70 lb. a day; and calculate on seven months, at 65 lb. a day. On this calculation, the forty cows produced 121 hundred weight; or three hundred weight (of 112 lb.) each cow. A dairy of 100 cows produced, on a par of years, five hundred pound worth of cheese yearly. Supposing the par price was 3s. 4d. a hundred; the weight, under this supposition, was 300 cwt: or, as before three hundred weight each cow.

"In conversing on this subject, with the man best able to adduce the requisite data, we were led into calculations; which, though they only prove, with respect to the annual produce of cheese in this district, the well ascertained fact that it produces from a thousand to twelve hundred tons a year; yet, in other respects, they are interesting; and place the rural economy of the district, as a dairy country, in a more striking point of view, than could, perhaps, be effected by any other means.

"It is, however, sufficiently ascertained, by annual experience, that three hundred weight of cheese may be taken as a fair estimation of the produce of a cow. From two hundred and a half to three hundred and a half, according to a variety of circumstances, includes, perhaps, the produce of every dairy in every year. It appears to be likewise sufficiently ascertained, by a long course of experience, that the aggregate produce of the district, is, on a par of years, eleven hundred tons. Hence it follows, on these premises, that the number of cows applied to the purpose of the dairy is seven thousand three hundred and odd. Consequently, if we allow four acres to a cow, the number of acres appropriated to the dairy, in this district, is somewhat less than thirty thousand.

"But the hundred acres, on which the above calculation was founded, are above par as to quality; and it is probable that, on a par of land each cow occupies more than four acres.

"On the whole we may venture to set down, in numbers sufficiently accurate to convey general ideas, that the Vale contains fifty thousand acres of surface; that two thirds of it are occupied by cows; that the cows are in number from seven to eight thousand; and that their annual produce of cheese is from one thousand to twelve hundred tons."

After Mr. Marshall had treated thus largely on the management of the Gloucestershire cheese-making, he proceeds as follows, on the method observed in North Wiltshire; and says:—"The species of cheese made here are various. Early in spring, soft thin cheeses are made, and sent up weekly to the London market. Some dairies, it seems, put the whole, or a principal part, of their make in nets. But the common make of the district consists of

"Thin cheese,

"Broad-thick, and

"Loaf-cheeses.

"The thin and the broad-thick sorts are similar to those of the Vale of Berkeley; and are, I understand, sold in London as double and single Gloucester. It is the narrow loaf-cheese, which goes under the name of North Wiltshire cheese; and which has of late years become so high in fashion as to fetch fifteen or twenty shillings a hundred-weight more, at market, than thin cheese,—of perhaps a superior specific quality.

"It may reasonably be asked, why is any other species made

made in the district. The answer is, every one makes loaf-cheeses who can, with any degree of certainty. They not only require more skill, and more labour, than thin cheeses; but it is generally believed that much depends upon the ground from which they are to be made. The fact is, I understand, that more than half the make of the district goes to market, in the form of thin cheese, which, at present, is not worth more than 27 to 28s. a cwt. while not one fourth of it is sent in loaves, which, notwithstanding the low price of cheese in general, is worth from 45 to 50s. a cwt.

"Loaf cheeses, however, have their disadvantages; though not equal to the present disproportion of price. They require not only more labour, but more press-room; and what is still more inconvenient, especially to the necessitous, they do not come so quick to market; requiring a much longer time to ripen in, than thin cheeses: consequently more loft-room is likewise necessary.

"Nevertheless, these inconveniences are inconsiderable, when compared with the advantage they have at market. Every man, therefore, whose skill and grounds will permit him, and who is not in necessitous circumstances, makes loaf, or thick cheese; which, in general, bears a price approaching to that of loaves.

"The management now requires to be particularised.

"In large dairies, cheese-making is continued throughout the year. Not only cheese for the family; but factor's cheese, also, is made through the winter season. In one dairy, I saw a very considerable parcel of broad-thick cheese, which was literally made in winter. Many tons of factor's cheese is every year made, in this district, entirely from hay; which, if good, is said to afford not only closer, but richer cheese, than grass. Winter-made cheese, however, is long in ripening, and is liable to be scurfy and white-coated. But time overcomes one of these disadvantages, and a coat of red paint the other.

"The specific quality of the milk is not here debased. The milk is run neat, or nearly neat, from the cow. The Gloucestershire practice of keeping a little out, for milk butter, is not here in use. It is not, at least, the common practice of the country for the cheesemakers to sell milk butter. In one or two instances, which I attended to more closely, not a drop was added to the new milk neat from the cow.

"The colouring of cheese has been long a practice, in this district. The oldest dairywoman I conversed with (sixty or seventy years of age) does not recollect to have seen cheese made with its natural colour. She remembers very well the introduction of the stone-colouring; the preparation of annotta, now in use; and has herself made use of the powder-colouring, faunders, which she says was usually boiled among a little milk, previous to its being put into the cowl.

"At present, the material, and the method of using it, is the same as in Gloucestershire; except that a new species has lately made its appearance; giving the milk and the curd a beautiful yellow hue; very different from the redness communicated by a superfluity of the common colouring. The base appears to be annotta; the difference being in the preparation.

"The colour preferred, by the cheese-factors of this district, is that of well-coloured bees-wax. Cheese of this colour will fetch more, by some shillings a hundred weight, than pale under-coloured cheese, or that which is too highly reddened.

"I met with nothing new, in this district, respecting rennets, except in one dairy; in which a peculiar mode of preparation is made use of.

"The usual method is to make as much, at once, as will last several days; perhaps weeks; or the whole season. But, in this instance, it is made fresh every day: that is, fresh brine is added every day; and never more than two vells—here provincially, rades—are suffered to lie in the jar at once. The older of them is marked with a skewer; and as soon as it grows stale, is taken out, and a fresh one added.

"This method of preparing rennet has been now continued through two or three generations. All I can say farther of it is, that the dairy, in which it is used, produces (if any one dairy has a decided preference) the best cheese of the district: but whether from the rennet, the ground, or the management, or from the three jointly, is by no means evident.

"The milk is universally run as it comes from the cow;

or as it happens to be lowered by the little skimmed milk, which is put into it. Its degree of heat I never saw tried; not even with the hand. It is said that, in very close weather, the first milking is sometimes kept in separate vessels, or spread thin in a whey-lead; but in general, I apprehend, its degree of heat, during the summer season, is never attended to. A fact, which I could not have believed, had not my own observation, strengthened by the thermometer, convinced me of it. I had conceived, that the superior excellency of the Gloucestershire management consisted very much in running the milk cool; and expected to have found it run still cooler in Wiltshire. But the following memorandums, accurately taken, are a convincing proof of the contrary.

"Swindon, Monday evening (21 July, 1788). Heat of the air in the dairy-room 60°: milk 8½°: uncovered: came in one hour and ten minutes: whey 85°: curd of a middle quality.

"Deyhouse, Tuesday evening. Air 63°: not covered: came in half an hour: too much rennet: whey 86°: the curd untender; but far from being of a bad texture.

"Westleycot, Wednesday morning. Air 60°: uncovered: came in three quarters of an hour: whey 84°: the curd of a good quality.

"Shaw, Wednesday evening. Air 62°: milk 87°: not covered: came in about an hour: whey 86°: (quantity very great:) the curd of a good quality.

"Avon, Thursday evening. Air 60°: milk 88°: closely covered with a thick woollen cloth, to make the top and the bottom come together: came in about an hour: whey 87°: the curd very good.

"Foxham, Friday evening. Air 60°: milk 91°: covered with a thin cloth: came in one hour: whey 89°. Nevertheless, the curd delicately tender.

"The management of the curd depends, in some measure, on the species of cheese. Thin cheese requires the least care and labour; and thick cheese less than loaves; which require the best skill and industry of the manager.

"In this department of the cheese manufactory the North Wiltshire dairywomen excel. It appears to be their forte. In it they seem to think the principal art consists. It will therefore be proper to descend to its minutiae.

"Breaking is done entirely with the hand and the dish: no knife in use, here, as in Gloucestershire. In some dairies, great caution is observed in the first fracture of the curd; which is done, either with the hand, or the dish, moved gently in the centre of the cowl; dividing the curd into large fragments, so as to let out the whey, leisurely, to prevent its carrying off with it the fat of the curd. When the curd has sunk a little way down in the whey, it is broken more freely; and having stood again to subside, and the clear whey on the top being laded off, it is reduced to a degree of fineness proportioned to the species of cheese. For thin cheese, it is broken as fine as curd generally is in Gloucestershire; for thick cheese, still finer; and for loaves, it is reduced, as it were, to atoms.

"In some dairies, it is violently agitated among the whey, with the hands, throwing it up from the bottom of the cowl, making it boil up at the top, like a strong spring gushing out from below the surface. This is called beating it: a practice which is objected to by judicious dairy-men; though I see most dairywomen do it, more or less, in the last breaking in the whey.

"One general remark, respecting the dairywomen of North Wiltshire, requires to be made. It is customary, even in the largest dairies, for the ostensible manager, whether mistress or maid, to perform the whole operation of making cheese; except the last breaking, &c. and the vating; in which she has an assistant. But this, in a dairy of eighty or a hundred cows, is too great labour for any woman: it is painful to see it. In one instance, in this district, a man was employed in this laborious department: and, in a large dairy, it is certainly man's work. A curd-mill in Yorkshire would lessen the labour considerably.

"It is in the final breaking the curd-mill is used. The labour of doing it by hand, when a large quantity of curd is to be broken, is almost intolerable. In a large dairy, a curd-mill must be found very valuable. This utensil consists of two rollers working in a thin deep chest, one above the other; on the principle of the common cyder-mill of the southern counties. The upper one is stuck with iron spikes, an inch long, and 1½ inch asunder. The lower one is closely set with bevel-headed nails, rising with a sharp angle about a tenth of an inch out of the surface of the roller.

The curd, partially broken, is put into a hopper, the bottom of which is the upper roller; which working against the side of the box, prepares the curd for the bottom roller; which being finer, and working closer, grinds it down to small granules. The rollers are about six inches diameter, and fifteen inches long. They are both of them turned by one crank, put on one end of the axle of the upper roller. On the opposite ends of the rollers are fixed two even-toothed wood wheels; working in each other, and giving motion to the lower roller.

"The ordinary practice is to lade off the whey as it rises; pressing down the curd with the bottom of the lading dish; to sink it the faster, and render it the firmer.

"In one instance, and this in a dairy whose practice is intitled to the first degree of attention, the curd, instead of being pressed with the back of the dish, is, while yet suspended in the whey, gathered, with the bowl of it, to one side of the cowl; first carrying it gently round the cowl to collect the curd more effectually. The whey by this means is got off much clearer, greener, than it is when the curd is pressed, in a soft pappy state; a practice which, undoubtedly, impoverishes the cheese.

"Most of the whey being got off, the cowl is heeled (in the practice) to get the curd into a mass on one side of it. The cowl is then replaced upright; the skirts of the mass cut off and piled upon the rest; the mass gashed with a long knife; and the whey laded off; fopping it up dry with a cloth.

"The mass of curd is now pared down slice after slice, (about an inch thick) and piled on the opposite side of the cowl; at intervals, pressing it close with the hands, and gashing it with the knife, to let out the whey more effectually. The whole being thus gone over, the whey, which has been by this means extracted, is laded off and fopped up with a cloth, as before; and the curd piled a third time; and, in some dairies, a fourth time; slicing, gashing, and pressing it with the hands; making it, by this means, in a manner perfectly free from whey. A practice, which was new to me, and which is, perhaps, peculiar to North Wiltshire.

"In one instance, and that in the practice of a most intelligent and experienced dairywoman, I observed an improvement of this method of freeing the curd from the whey. Instead of pressing the pile, at intervals, with the hands (a power which, when the quality of curd is large, has but little effect) a vat was put upon it, and loaded with cheese weights; a cloth being spread over the bottom of the vat to prevent their sliding. As the pile was carried up or gashed, the vat was moved from part to part, so as to give an even pressure to the whole. By this means the whey is, in a manner, wholly extracted.

"Some few dairies, it seems, double press the cheeses: that is, put the curd in the press before it be scalded, agreeably to the Berkeley practice. But it is considered as an inferior method. It certainly reduces the richness of the cheese, more than the practice which is here described; and which, alone, fell under my observation, in Wiltshire.

"The ordinary method of scalding, here, is similar to that which has been described in the Gloucestershire practice. The mass of curd is broken to different degrees of fineness; proportioned not to the species of cheese, altogether; but according to the skill of the dairywoman. In a first-rate dairy, making loaf-cheeses, I saw it broken very roughly.

"The quality of the scalding liquor too, varies here, as in Gloucestershire. Some scald with whey; some with water; others with water lowered with whey.

"The heat of the scalding liquor likewise varies, even in the ordinary practice of the district, very considerably: not, however, as in Gloucestershire, according to the quality of the given curd; but according to the custom of the given dairy. Custom, however, which may have been founded on long experience, and may be peculiarly adapted to the ground, from which the curd is produced.

"In the ordinary practice of the district, the North Wiltshire dairywomen may be said to scald highly. Five, out of the six dairies, whose scalding liquor I tried with the thermometer, heated the liquor from 102° to 140°. The heat of the mixture of the liquor and curd being from 92° to 110°. So that, in the ordinary practice of the country, the milk is not only run, but the curd is scalded, much higher than in the Vale of Berkeley. A circumstance which I did not expect to find in North Wiltshire; whose cheese is characterised by a soft saponaceous texture; dia-

metrically opposite to that hardness, toughness, which scalding appears to give to the curd in the first instance.

"But if a degree of surprize arises from the ordinary practice of the district, an excentric practice; which I was favoured with the inspection of; must be a matter of some astonishment. What renders this instance of practice the more interesting, is its being struck out and pursued, by one of the oldest, best experienced, and most intelligent dairywomen I have any where conversed with. In this instance the curd is literally scalded, with almost boiling water qualified by a dash of cold water, before it be thrown into the cowl; to prevent its catching the curd. The actual heat 192°.

"It is proper to be understood, however, that, in this case, the curd is not crumbled, or broken in the usual manner, before the scalding liquor be thrown among it; but is cut into checkers, or dies, of about a cubical inch each: with the same knife, used in nearly the same manner as in slicing it.

"Another peculiarity of this practice is, that the curd is salted before it be scalded, a handfull of salt, to every cheese, being strewed over the checkers, spread regularly on the bottom of the cowl, and worked in evenly among them.

"This is done in conformity with the general principle of this practice: namely, to keep the fat in the cheese; the salt being thought to harden and close the outsides of the cubes; thereby preventing the butyraceous particles from being extracted by the scalding liquor. The fact is, the water, instead of being made as rich and thick as butter-milk, is left in the cowl after the curd is taken from it, thinner than the clearest whey, and without a speck of oil on its surface.

"In one dairy, which I had an opportunity of observing, in this district, the scalding liquor was covered with a sheet of oil, which might have been skimmed off its surface in quantity: while in others, whether they were scalded higher or lower than this, not a drop of oil was to be seen; though the management in every respect was similar. The ground, therefore, seems to be the cause of this difference; which, to me, appears to be a circumstance singularly interesting.

"Nor is scalding with boiling water, cutting the curd, and salting it before scalding, the only peculiarities of that singular dairy. The dies of curd having been stirred among the scalding liquor, and lain a minute or two to be thoroughly heated, are taken out of the scald, which yet retains a heat of 130° with dishes, and immediately put into the vats, as hot as the hands can possibly bear. They press into the vats like bees-wax, that has been very much softened by heat, or as cheese, which is slightly toasted. Two or three vats being filled, they are set in a shallow tub, placed on the dairy floor, and a loaded vat put upon them, to close the curd while warm: in my opinion, an admirable stroke of practice: it had long struck me, in theory, as being likely to be eligible; but was among the last things I expected to meet with in actual practice.

"Thus, not only richness and a closeness of texture are probably obtained, by this course of treatment; but the farm on which it is used is considered as being difficult to make cheese from: and it is believed, that the method of treatment which is here described, is the means of preventing the cheeses from heaving. The fact is, the cheese (thin cheese) appears to be, with this treatment, above par as to quality.

"The methods of vatting in the other dairies, which I examined, were various. In some, the scalding liquor was laded off, and the curd rebroke and salted in the cowl; while in others, the curd was taken warm out of the liquor, and salted in the vat; thin cheese with a small handfull in one layer; thick with two small handfulls in two layers, loaves with two handfulls in three or four layers; spreading and rubbing in the salt evenly among the curd.

"The dairy which has been mentioned, as being celebrated for cheese of a superior quality, scalds highly (130°) and vats the curd warm out of the scalding liquor; while it retains 105° of heat. Nevertheless, in a neighbouring dairy, which makes very good cheese, the curd is put cold into the vats.

"What can we infer from the aggregate of these circumstances? There appears to be but one alternative. Either different grounds require very different management, or the art of cheese-making is less mysterious than has hitherto been imagined. To make good cheese sometimes, from some grounds, is, I believe, a very easy matter; but to make

make good cheese at all times, and from all grounds, on a certainty, is what no person has yet been able to perform. Nevertheless, I am more and more clearly of opinion; that with leisure and perseverance; assisted by a degree of chemical knowledge, and a proper apparatus, this object, difficult and desirable as it may be, is attainable.

"1. The management of the cheese in the press is, here, much the same as in Gloucestershire. They are generally salted twice; (only one instance of the contrary;) and remain in the press a time proportioned to the given thickness: thin cheese, three or four meals: thick cheese, four or five meals: loaves, five or six meals.

"From the press they are carried into rooms, fitted up with shelves, for their reception: some of them very commodiously: an entire lining round the walls, and, perhaps, a stage or two in the middle of the room; with only gangways, wide enough to pass conveniently between them.

"On these the young cheeses remain until they be cleaned, or until the shelves be full; turning them as often as the weather and their respective ages require.

"The method of cleaning varies: in some dairies, the summer cheeses have nothing done to them, except having their edges wiped. The blue coat rises soon enough, and sufficiently, to hide their roughnesses. In others, they are only scraped dry (by the milking man,) and in others washed and brushed with a pail-brush, without being scraped. I met with no instance, in which they are soaked by the hour in water, and afterwards scraped, as in Gloucestershire. Some object even to wetting them: all to soaking them; not only as making them soft, thereby checking their ripening, and backening their sale, but as being dangerous to the cheeses; which, if they have the smallest cracks, absorb the water, and receive irreparable injury.

"No painting; except of winter-made cheese; which generally throws out a white scurfy coat, difficult to be got rid of, in any other way. These are covered with a uniform coat of paint: but the general make of the country are, as yet, permitted to go to market in their own blue coats.

"From the shelf-room they are taken to other rooms, provincially lofts, and spread over the floor; which is repeatedly cleaned, by rubbing it with cloths; but not prepared with succulent vegetables; except for old thick cheeses, in order to prevent or kill the mites, which thick cheese is liable to be infected with, before it be ripe enough for market. In this case the leaves of the alder are, I believe, principally used.

"In one dairy, (Deyhouse) I observed an admirable arrangement of cheese-rooms. The shelf-room is immediately over the dairy-room. And the lofts, over the shelf-room; with trap-doors in each floor to hand the cheeses through. A plan which saves much awkward carriage, and might well be adopted in every dairy that will admit of it.

"The cheese of this district, like that of Gloucestershire, is bought up principally by factors, who live in and near the district, and who send it mostly to the London market; the younger by land, the older by water-carriage. One factor (or copartnership of factors) is said to send seven or eight hundred tons annually.

"The small cheeses are generally drawn from the larger dairies once a month; and down, perhaps to five or six weeks old. The large cheeses require a much longer time before they be marketable. The winter, and early spring-make, go off in autumn: the latter make the ensuing spring.

"The produce of milk I had not sufficient opportunity to attend to accurately. To that of cows by the day I was most attentive. This ran in every instance, except one, from 2 lb. to 2½ lb. a cow. The one exception, somewhat below 2 lb.—2½ lb. has, I am told, been produced from cows which came well in together, and were in full milk.

"The produce of cows by the year is, in this district, almost incredible. Three to four hundred weight a cow, is, I was assured on all hands, the common produce. Four and a half not unfrequent. Four hundred nearly the par produce. There is a well-attested instance, in which a small dairyman sold thirty five hundred weight from seven cows; besides what was used in his family. But the cows were in their prime, and extraordinary milkers.

"There are two reasons, why the produce of cows in this district exceed that of cows in Gloucestershire. The cows are larger, and the season of making longer: cheese

is here made the year round; whereas, in Gloucestershire, the season of making lasts little more than several months of the twelve.

"The annual produce of the district has not, perhaps, been calculated: I met with no estimate of it. Supposing one third of the district to be appropriated to cows, and allow that each acre thus occupied yields one hundred weight of cheese (calculating on four acres and four cwt. to a cow) the aggregate produce is, at least, one hundred thousand hundred weight; or five thousand tons a year.

"Admitting that there is a market for the whole produce of the district, in loaf-cheeses, and taking the medium disparity of price between loaf-cheeses and thin cheeses, to be ten shillings a hundred-weight, or ten pounds a ton; and allowing that, at present, half the produce of the district, sent to market in the form of thin cheese, North Wiltshire is sustaining, annually, a loss of twenty-five thousand pounds, through the present imperfection of the art of cheese-making."

Mr. Marshall, in a very able manner, then makes some general observations on the subject of cheese made in Gloucestershire and Wiltshire; and says, "The species of cheese, produced in this island, are various. Its markets, however, are principally filled with two species: the one of a dry loose contexture, and of a rough austere flavour: the other, milder to the taste, and of a close waxlike texture. The former is sold under the name of Cheshire cheese; and is, I believe, chiefly the produce of that county: the latter under the name of Gloucestershire cheese; provided its quality entitle it to that distinction: if not, it takes, I believe, in general, the name of Warwickshire cheese; but, in reality, is produced in several counties. The products of Somersetshire, Wiltshire, Berkshire, Oxfordshire Gloucestershire, Worcestershire, Warwickshire, Leicestershire, Staffordshire, and Yorkshire, are very similar: all of them as different from the produce of Cheshire, as if they were manufactured from a different material.

"It is this milder species, which is a principal article of food, of various classes of working people; and which, therefore, claims the first and the highest attention.

"Gloucestershire has long held a decided superiority in the production of this article of human food. At present, North Wiltshire is a competitor, and bids fair to take the lead. The practices of the two counties are here, I believe, accurately, and the more difficult passages, fully registered, down to their lowest minutiae.

"Therefore, without any view to blazon my own industry, or to set off, unfairly, the work I am executing, I will venture to suggest, that whoever shall examine, with attention, the three separate practices, which are here registered, will know more of the subject under examination, than any individual of the two counties knew at the time of registering.

"The knowledge, even of practitioners, is in a manner wholly confined to their individual practice; or perhaps to that of some few confidential neighbours.

"The manufacturing of cheese is not like the cultivation of lands. This is a public employment, open to any one who travels across the site of cultivation; that, a private manufactory, a craft, a mystery, secluded from the public eye: and what may appear extraordinary, the minutiae are seldom familiar, even to the master of the dairy in which they are practised. The dairy-room is consecrated to the sex; and it is generally understood to require some interest, and more address, to gain full admission to its rites.

"The information I have been favoured with, while it shews the superior skill of the Gloucestershire and Wiltshire dairywomen, and exhibits the best practice of the kingdom at this day, proves, in a striking manner, the imperfection of the art; even in these long-experienced and enlightened districts. Gloucestershire acknowledges a degree of decline; and Wiltshire, notwithstanding the spirit of improvement has evidently been some time on the wing, confesses, with equal frankness, that it has not yet been able to reach any degree of certainty, much less perfection.

"At present, the art is evidently destitute of principles. So far from being scientific, it is altogether immemorial. It may be said to be at present, a knack involved in mystery. Therefore, its fair professors, though they may claim a degree of natural cleverness, to which we have no pretension, and which, only, could have raised the art, in the extempore way, in which it is at present practised, to the height it

It has attained; having tried their skill, alone, without obtaining the requisite degree of excellency, can have no good objection, now, to let us try our joint endeavours. And I call upon every man of science, who has opportunity and leisure, to lend them his best assistance. And would wish to recommend to intelligent dairy-farmers to be more attentive than they appear to be at present, to what so nearly concerns their interest.

"This in apology for the following observations:

"Attending to the minutiae of different dairies, and seeing the effects of different modes of management, a variety of ideas would, of course, rise spontaneously. Some of them fancying improvements, in the particular management I was observing, and other proposing a transfer of it, to the different districts of the island. Such of them as appear to be entitled to attention, and are not interspersed in the foregoing relations, will be given in this retrospective view of the subject.

"As a ground-work, it will be proper to ascertain the good and evil qualities of cheese; the excellencies to be obtained; and the defects to be avoided. In defining these, however, we must not pay regard to the palates of individuals. There is a kind of depravity in some men's tastes, with respect to the article of food under consideration, which would frustrate every attempt at definition. We must, therefore, have an eye to those good and bad qualities of cheeses, which raise them in value, or depreciate them at market. Qualities of which the different dealers, in this article, have ideas sufficiently accurate for our purpose.

"Cheese of the first quality; that which comes as near perfection as the nature of it admits of, or as art can probably approach, is of a close even contexture; of a firm but unctuous consistency; of a mild flavour, while young; acquiring, by age, an agreeable fragrance. If a cheese of this quality be ironed, it has somewhat the appearance of firm butter; or of wax moderately warmed. If the plug be gently rubbed, the substance of the cheese seems to melt under the finger which wears it down, as it would fine clay duly moistened. If the end of the plug be pinched, it yields to the pressure without crumbling; grinding down, between the fingers, to an impalpable matter, cheese of this description, like wine of a good vintage, improves, by age, in mellowness and flavour.

"The defects of cheese, in this district, are, porousness, hollowiness, dryness, and partial rottenness: the fly, so much to be dreaded in Norfolk, is not known here, where maggots are thought to breed naturally in good cheese.

"The substance of cheeses, having this defect, may be sufficiently unctuous and cohesive; but the contexture is broken, by cells of different magnitudes; and the flavour invariably bad, being pungent to the taste, and offensive to the smell.

"Hollowiness appears to be, generally, though not always produced by the same cause, operating in a different manner. In that, the expanding air is distributed: in this, it is collected: cleaving the cheese in the middle: making it bulge out generally in the center; but sometimes partially toward one edge. The effect, too, is the same: both of them leaving, in most cases, a pungency of taste, and disagreeableness of smell; qualities which are increased by age. Porousness seems to be a weaker effort; hollowiness a higher state of defect.

"The contexture of cheese, under dryness, is loose and incohesive. If a plug be drawn, it is hard and dry to the touch; and crumbles under pressure. It wants unctuousness and flavour; being insipid to the taste, and inodorous to the smell. This description of cheese is likewise liable to cleave in the middle.

"Whey-botches appear on the surface; and are understood to be caused by what is called slip-curd, namely curd, from which the whey has not been duly expressed. This theory, however, does not appear to me to be altogether satisfactory.

"The causes of the other defects are important objects of enquiry.

"The dryness is understood to be owing to some degree of acidness in the milk, at the time of coagulation; and may originate in other circumstances.

"The cause or causes of the other defects may be still more involved in uncertainty. Since the doctrine of airs has been agitated, a general idea has been suggested, that fixed air is the latent cause. But I have not met with any reason tending to explain how this fixed air is let loose; or

why it should leave; invariably, a pungency of taste and rankness of smell behind it.

"That an expansion of air takes place is evident; but the efficient cause of this expansion may be difficult to explain. It may, however, be taken for granted, that whatever is the primary cause of the pungency and rankness, which follows, is the primary cause of the expansion; which, indeed, is not, in this place, the object of enquiry. For it is not the expansion, but the pungency and rancidness, which constitute the defect.

"To endeavour to ascertain the cause of the pungency and rancidness, I made some experiments with cheese, possessed of these qualities in a superior degree.

"The specimen subjected to these experiments was of the porous kind. The pores or cells varying from the size of a mustard-seed to that of a bean: all of them glazed within; and to the naked eye, apparently varnished with a yellow resinous substance; but, in a glass there appeared to be no coat of matter. On being scraped with the point of a needle, the insides of the cells rose in the same snowy flakes, which every other part of the substance afforded: the colour of the loosened particles purely white; notwithstanding in their consolidated state they were of a dark yellow; a wax-colour; the cheese having to all general appearance been coloured; yet not a particle of the colouring material discoverable. One minute bundle of resin-like matter I found lodged among the substance; but none in the cells. The smell fetid; the taste bitter.

"Experiment I. Tenth of July, 1788. Placed two pieces about a cubical inch each, in separate glasses: covered one of them with cold, the other with boiling water.

"Eleventh of July. The colour of the surfaces of both of them is changed. That subjected to the cold water is become pale: that to the hot, purely white. The water, in both cases, fetid. The cold water, the stronger-flavoured, and the higher-coloured; the hot, milder and paler. On the top of the hot, a few small particles of oil swim; on that of the cold some large specks appear.

"The heat of the boiling water has softened the pulp, but not the rind of the cheese, so as to disfigure the cube, and fix it to the bottom of the glass. On pouring off the water and raising up this piece, the part which was in contact with the glass is still of a yellow colour; and retains its fetid smell; while the upper surface is pale and in a manner scentless. The scent of the other piece is weakened; but much of it still remains. The taste of both pieces lessened; especially that of the heated piece.

"Experiment II. Eleventh July. Covered a piece of the same specimen, (an inch square and about a quarter of an inch thick) with rectified spirit of wine. And put another piece, (a quarter of an inch cubical) into a vial of the same spirit.

"Twelfth July. No apparent change of colour or contexture except that the piece in the phial is somewhat paler than when it was immersed. The glazing on the insides of the cells is still perfect. Nevertheless, the smell is entirely gone, and the taste rendered perfectly mild: the bitterness lost. But quere, are they dissipated, or only disguised by the spirit?

"Experiment. III. Twelfth July. Bruised some of the pulp of the same specimen (dry and hard) with the blade of an ivory knife; the granules small, but not evenly reduced. The colour, after bruising, nearly white. Put equal quantities of it into three separate glasses: covering one with cold water, one with boiling water, and the third with spirit of wine.

"Fourteenth July. That upon which the spirit was poured, underwent no evident alteration; except that it regained part of its colour. This settled down and laid close, but loose at the bottom of the glass. The smell entirely fled, or disguised.

"The cold water effected no change, even of colour. The subject would not mix freely with it. Part of it sunk; part swam on the surface. Yesterday, not having been disturbed, it afforded little or no smell; but this morning, on being stirred up, it proves as fetid as the original cheese. The crumbs, which now subside, have a somewhat curd-like appearance.

"The hot water produced, immediately, a milky liquor; which presently divided into curd and whey; exactly resembling scalded curd, with its scalding liquor standing upon it. The curd as white almost as snow; the water pale and oily. Yesterday, the water emitted no smell: to-day, the

the curd which has formed itself into a compact mass at the bottom of the glass; a cake of perfect cheese-curd, is in a manner scentless and tasteless.

"Thus, from the whole, and from every part of this evidence, it appears, that the immediate cause of the pungency and rancidness of cheese is an essential oil, which spirit of wine dissolves; and which is rendered volatile in boiling water.

"The excellencies and defects of cheese being enumerated, and the probable cause of the principal defect pointed out, it will now be proper to view the following heads separately, examine still farther into this cause, and endeavour to point out some probable means of avoiding its evil effect: and, at the same time, to endeavour, by scattering a few rays of light on the general subject, to relieve it, in some small degree at least, from its present obscurity.

"It is a fact well established, that the season has great influence on the quality of cheese; especially on the defect more immediately under notice. In 1783, a dry hot summer, scarcely any dairy could make good cheese. In some dairies more than half the make was hollow; and even in the best dairy I had an opportunity of examining, numbers were eye: while in a common season, and more especially in a cool summer, the same dairy has scarcely a defective cheese.

"This corroborates the idea of an essential oil being the cause of the defect. It is annually proved in the practice of numbers, that plants in general afford a quantity of essential oil, proportioned to the warmth of the season they grow in. It is likewise known, in the dairy counties, that cheeses made from the grass of autumn seldom or ever heave. At that season the finer blade-grasses are chiefly produced. Few flowers, or aromatic plants, mix with them. Besides, the weather being generally cool, a less proportion of oil is probably raised at that season of the year.

"It has been observed, that the best cheese is made from the least productive soils: not, perhaps, fatter than cheese made from richer, more productive soils; but freer from the defect under notice. This is accounted for in the principle laid down: the unproductiveness of the inferior soils has been said (without any regard to this theory) to be owing to their coolness: another striking circumstance in favour of the principles offered.

"Another observable circumstance, with respect to soils, is that of their being injured by manuring: it being a fact sufficiently ascertained, in each district, that close, well-flavoured cheese cannot be made, or is with much uncertainty produced, from land that has been recently manured. But whether the manure, itself, be the immediate cause; or whether it only change the herbage, appears to be a moot point.

"Water is a subject to which no one seems to have paid the smallest attention. I have not been able to gather any information respecting it, which is interesting. Nevertheless, it is probable, that much may depend upon it. It seems reasonable that a plenty and purity of water should be conducive to the production of good cheese: it is probable that a deficiency of water may increase the proportion of acrimony in the milk.

"Each species of plants has its peculiar organization, which either enables it to make choice of its food, or gives it a faculty of changing, whatever it imbibes, to its own specific nature; or, which to me is more probable, each plant is possessed of these two powers jointly. It is evident, that the qualities of mild, sweet, bitter, acrid, and poisonous, are all of them produced by different plants growing in the same soil.

By analysis, their component particles are found to be extremely different in proportion, at least. Thus one plant (the fava) yields a quantity of fluid essential oil more than equal to one seventh of its own weight; while another (the rose) seldom perhaps affords the proportion of one to a thousand. Hence, on the theory offered, much, very much indeed, may depend on the specific quality of the herbage.

In North Wiltshire, an experienced and very intelligent dairy-woman observed, that when the crazy (the crow-foot) is in full blow, she finds her cheese particularly inclined to heave, while a dairy farmer of the highest class, in the same district, has observed, that when the creeping trefoil, white clover (*trifolium repens*) has been in full blow, and in particular abundance, he has heard the loudest complaints of the licentious disposition of the cheese.

It is not probable, that any one species of plants is the

sole cause of the disorder. Almost every cheese has its peculiar flavour, and its different degree of acrimony. Nothing is more likely to give that almost caustic quality, which some cheeses are possessed of, than the common and the bulbous crowfoots: not only their flowers, but their leaves, are singularly acrid. On the other hand, there are several circumstances which render it probable, that a redundancy of the creeping trefoil tends to aggravate the disorder. Dry seasons, by keeping the grass short, give it an opportunity of spreading. Manure is well known to encourage it; sometimes in a singular manner. Sheep-feeding pasture grounds produces a similar effect; partly owing, perhaps, to the blade grasses being kept short; and in part to the soil being meliorated by a fresh manure: and it has been observed that a suite of cow-grounds, which have been occasionally fed hard with sheep, are very difficult to make cheese from: while a few sheep among cows may, by picking out the clover, be serviceable to the dairy.

"Other plants, probably, have a bad effect; and to ascertain them is an object worthy of attention. It is probable, however, that the mischief is effected by some common article or articles of herbage; and not by a few weeds which can easily be extirpated: nevertheless, it would be useful to know, not only the herbs, but the parts of them, which cause the evil.

"The age of herbage may likewise influence its effect. It has been generally understood, that cheese of the first quality cannot be made from young leys: nothing but old turf being esteemed equal to its production. I have been informed, however, that there is, or was, an instance, in these districts, in which good cheese was made from fresh land; from land which was kept alternately in corn and grass. In my own opinion, more depends on the quality of the subsoil, and the species of herbage, than on its age: or, in other words, the effect appears to me to be produced by the species of herbage and the temperature it feeds in. I have traced the roots of old turf, in different parts of this district, to two or three feet deep. Here the plants, notwithstanding the subsoil may be absorbent, probably feed in a cool situation, undisturbed by the immediate influence of the sun, and on soils thus situated, much may depend on the age of the herbage: but it strikes me that young grass, of a proper species; may, upon cold land, produce good cheese, though it should feed near the surface. This, however, by the way.

"From the aggregate of the foregoing evidence we may infer, that the defects of porosity and hollowness are principally owing to the species of herbage: very much, however, depending on its state of growth; very much on the season; much on the nature of the subsoil; something on the age of the sward; and something perhaps on the soil. I wish, however, to have it understood that the inference here drawn is not considered as conclusive: all that appears to me is its probability. The theory of an art is seldom brought to light in a state of perfection. It generally requires to pass, progressively, the several stages of infancy, adolescence, and manhood; rising by slow steps to maturity.

"The present imperfection of the art stands confessed on all hands in management; and, even with the joint assistance of science, it may never be raised to perfection. Nevertheless, it is evidently capable of improvement, and of being raised nearer to perfection than it is at present. Different grounds (a term which aptly comprehends herbage, soil, and subsoil) may require different modes of management: but so it is in the raising of corn; dissimilar soils require dissimilar treatments: yet we see fine crops of wheat growing on almost every species of soil. Coagulation appears to be a much less fickle process of nature than fermentation: nevertheless we find the art of brewing (in the larger breweries) is raised to a degree of certainty.

"The milk, the coagulum, the coagulation, the curd, and the cheese, will each require to be separately examined.

"In the milk; three things are here wanted:

"A taste of the quality of milk;

"A mode of correcting an evil quality:

"A gauge to ascertain the exact quantity;

"That some milk is sufficiently pure, to require no correction, is evident, from cheese of the first quality being made from it, genuine, as it is drawn from the cow.

"In all human probability, however, the cause of the defect, more particularly under notice, is lodged in the milk; and a taste to discover it would be valuable.

"In the Vale of Berkeley, I was told, there are dairy-women

men who will judge, by the smell of the milk, whether the curd to be produced from it will, or will not, make a heaving cheese.

"This circumstance is highly probable. For, if the heaving be caused by an essential oil, the smell is the easiest, and, perhaps, the most certain test it can be brought to. The odour of plants (in general) lies wholly in their essential oils. Draw off this, they become scentless; the whole of their odour being found in the oil. The various essences of the shops are no other than the essential oils of the several plants, whose names they respectively bear. And it appears to me more than probable, that were the effluvia which rise from milk warm from the cow, to be concentrated; that is, collected into a narrower compass, thereby encreasing the flavor, the quality might be judged of with sufficient certainty. A simple apparatus might be rendered applicable to this purpose.

"A redundancy of odour being discovered, the means of doing it sufficiently away would be the great thing desirable. It is probable, that a degree of odour, a due portion of flavour in the milk, may be necessary to the production of well-flavored cheese.

"If rancidity be the effect to be guarded against; and if essential oil be the cause of rancidity; an evident, and easy mode of purification presents itself.

"It is well known, that all essential oils are of a volatile nature. The heat of boiling water will cause all of them to quit their native substances. Some will quit and fly off with a much lower heat. In the loose state, in which they lie in milk, they might, no doubt, be easily dissipated. Ventilation alone would probably go near to effect the desired purpose. A small addition of heat would, perhaps, render it fully adequate to the intention. By an increase of heat, the end might be obtained with a degree of certainty.

"Two inconveniences would attend this mode of correction. An increase of labour; and a loss of time. But theory suggests another simple apparatus, adapted to common use, and manageable by the most ignorant dairy-girl, which would render the extra labour and the loss of time inconsiderable, compared with the advantage to be obtained by the use of it.

"In this place, it will be proper to mention an attempt, which has been made, in this district, to correct the milk. But not, from what I can learn, with much success. Before I made the foregoing experiments, it struck me, that some chemical preparation might be hit upon for this purpose; and that which is, perhaps, most likely to effect it, has been used in this instance: namely, the vitriolic acid: or, as it is commonly called, the spirit, or the oil of vitriol.

"A dairy-woman, who tried it, put about a tea-cupful into seventy or eighty gallons of milk. But she found it interfere with the rennet, so as to disturb the coming. That is, being a strong acid, it brought on a premature coagulation. She, therefore, laid aside the use of it. Nevertheless she, and others, who have given it a fuller trial, are of opinion, that it helps to keep down the cheese.

"This circumstance, it is observable, still farther corroborates the theory offered; and in an interesting manner; as it is an evidence, that the heaving, the immediate effect, is caused by an essential oil; a considerable portion of which the stronger acids have a power of fixing in a resinous state. It is, therefore, highly probable that, by a sufficient quantity of concentrated acid, the cause might be sufficiently overcome. But supposing this mode of correction to be practicable, the practice could not be recommended.

"At present, the proportional quantity of curd to a given quantity of milk appears to be very uncertain. A dairy-woman seems to be under no certainty, until she has, as it were, measured it in the vats. Running the milk cool is thought to lessen the quantity of curd. The proportion is thought to be greater in autumn than in summer. Some cows are thought to afford more curd than others. This is an interesting subject, and requires to be strictly enquired into.

"To come at this proportion, the first thing is to ascertain the exact quantity of milk. A rod graduated to the given cowl (by an exact gallon measure) would give it at sight; without the trouble, or the danger, of calculation being incurred.

"Notwithstanding the stomach of the calf is the established coagulum of milk for cheese; it may, or may not, be the best, which nature affords for that purpose. Coagulation may be produced in a variety of ways, and the best

ought to be sought for. The great object seems to be to reduce the whey to the most aqueous state possible. Not only the quantity, but the richness, and even the dietetic quality of the curd is, perhaps, given by the coagulum. The theory of coagulation appears to be, at present, imperfectly known, or not in any degree understood; though, perhaps, a subject of some importance, in medicine, as well as in rural economics.

"A test of the strength of the coagulum used, and a measure to ascertain an exact quantity, are much wanted: in order that a given quantity of milk might have a due quantity of proof coagulum assigned it. This, with a little industry, might no doubt be accomplished: and being once fixed on mechanical principles, neither time nor labour will be lost by it.

"The thermometer is a certain guide as to the heat of the milk; as well as of the air, in which it is to be coagulated. Thus far we might, therefore, go, on mechanical principles; and regulate the time of coagulation, and the quality of the curd, with a degree of certainty: provided the quality of the air, in which the curd is generated, have no influence, by its action on the process of coagulation, on the quality of the curd.

"I have observed, in one or two instances, that in a close muggy air, the curd has appeared to come prematurely, and to be of an inferior quality. But even should this, on due enquiry, be found to be a real circumstance in the general law of coagulation, its evil effect might, perhaps, by due attention, be guarded against. If any particular species of air should be found to be conducive to good cheese; either during the coagulation, or while the manufacture is carried on; how easily might the required atmosphere be given, either to the containing vessel, or to the room in general!

"The method of regulating the heat of the milk may be a thing of some importance. Water may, or may not, be proper to this purpose.

"The due length of time in coagulating, requires, likewise, to be enquired into. Perhaps a rapid coagulation, not only renders the curd tough; but, by giving a greater quantity, injures its richness. Hence, on a lean soil, it may, perhaps, require to be carried on more deliberately, than on a rich one. It will, I am persuaded, be found, on due examination, that the quality of the curd is in great part given by the period of coagulation.

"The point of maturation wants to be ascertained. I know no guide to it, at present, which can be defined with sufficient accuracy. If the curd be broken prematurely, a portion of it may be lost: if it remains too long before it be broken, some worse consequence may follow. Hence, it appears to be only common prudence to keep the vessel closely covered during the coagulation, that the whole may reach the proper state of maturity at the same time.

"Curd may be called the state of manufacture. The first step towards perfection is to provide a suitable material; the next, to manufacture it in the most perfect manner.

"Separating the curd from the whey is a point of management, on which the richness of the cheese, perhaps, very much depends. The object to be aimed at, in this operation, is to draw off the whey as clear, as green, as may be. For this reason, it ought not to be suffered to remix with the curd, after it has once been dislodged from its cells: much less to have the curd broken small among it; thereby saturating it with the richer particles. An apparatus, sufficiently manageable in common use, and one which would, probably, save much labour and much time, might, I believe, be rendered equal to this intention. Should it be said, that what is lost to the cheese is saved in the whey, the reply is, that the injury does not proceed from the quantity lost; but from the quality of the entire cheese being lowered, by the loss of part of its most valuable particles. If an inferior kind of cheese be required, the milk ought to be reduced, previous to the coagulation. From the rich soils of these districts, cheese of a superior quality may be made; though the curd be impoverished in the operation of making it. But on leaner soils, not a particle of the natural richness of the milk should, in strictness, be suffered to escape among the whey.

"Scalding the curd is an operation, which requires to be examined into. It is peculiar to this quarter of the kingdom. It may or may not be necessary to the production of cheese of the first quality. It unavoidably carries off a portion

portion of the richer particles of the curd. Were it not for this inconvenience, it is probable, that the cause of heaving might be broken by breaking the curd small, and scalding highly, be dissipated in this operation. Even when the curd is cut into cubes, we find that high scalding has a probable good effect. Cutting the curd, instead of breaking it, certainly preserves the richness, but may prevent the free escape of the offensive matter. Nevertheless, in the instance of practice referred to, it seems to answer the purpose required by the excellent dairy-woman who uses it. It has, indeed, more ingenuity in it than all the other operations I have met with in the art.

"Another circumstance in the operation of scalding is noticeable. It seems to be indisputable, that the curd should be scalded evenly. But, by the present method in use, the same cowl of curd is scalded with various degrees of heat. That which the scalding liquor immediately falls upon, is subjected, perhaps, to 150° of heat; while that which is afterwards stirred up among the liquor has not, perhaps, more than 100° . This, and the practice of leaving the cowl uncovered, during the coagulation, may account for the otherwise, perhaps, inexplicable circumstance of one cheese of a good, and another of a bad quality, being made from the same cowl of curd: a circumstance which is mentioned with confidence in different districts. If the curd be scalded, it ought, in my idea, to be plunged wholly, and instantaneously, into the scalding liquor; and not the scalding liquor poured upon the curd, in the manner in which it is at present. Some prudent dairy-women, I have observed, lower the first dash of scalding liquor thrown in, and stir the curd up among this; before the rest be added. This lessens the evil very considerably, but may not altogether prevent it.

"Salting the curd is a matter entitled to attention. It strikes me, that much, if not the whole, of the superior pungency, which is mostly observable in the Berkely cheese, may be owing to the great quantity of salt used in that district: while the mildness of that of Wiltshire, and especially of the two-meal cheeses of the Upper Vale, may arise from the comparatively small quantity which is used in these. The quantity of salt used in the Lower Vale is, in the established practices of the two Vales, twice, or perhaps, near three times as much as in the Upper: and although, in Wiltshire, the quantity mixed with the curd be full as much as in the Vale of Berkeley, that rubbed on the surface is very considerably less. This is a point of management, which experiment would readily determine. Something too, may rest with the method of salting. Whether the whole should be rubbed on the surface; or whether it should be partly or wholly mixed with the curd; or communicated in the form of brine, is a subject worthy of enquiry.

"Correcting the curd by some chemical preparation, so as to prevent the cheese from rising, may be practicable; but it is probable, that although the rising were to be prevented, some part at least of the badness of flavour would remain, after this mode of correction; which, in theory, is much less eligible, than that of purifying the milk, previous to the coagulation.

"The shape of the vat is not unworthy of attention. It is observable, that cheeses shrink in width, but not perceptibly in thickness: thus, a cheese made in a vat fifteen inches and a half deep, does not, at three or four months old, measure more, perhaps, than fourteen inches in diameter; yet retains a thickness equal to the full depth of the vat. This seems to be accounted for in the species of compression to which cheeses are subjected. Curd being a substance of a tough cohesive texture, does not, like water, or other liquid, press upward, downward, sideway, every way, and equally in all directions; but, in a vat of the ordinary form, is pressed much more downward, than it is sideway; more flatway, than it is edgeway: hence, in drying, the cheeses shrink principally in width; and hence, all cheeses of the common form have a necessary propensity to cleave in the middle. For the edge, or outer rim, having a greater quantity of surface for the atmosphere to act upon, shrinks faster, or attempts to shrink faster than the central parts of the disk; which, of course, acquire a natural propensity to budge out, to allow for the contraction of the edge; while the edge acquires a similar inclination to crack, to give the requisite circumference. If, however, a cheese be of a close cohesive texture, the powers gained, by this inequality in drying, may not be sufficient to cause either of these effects. But, if it

happen to be of a loose crumbly texture; or, if the texture should be broken or opened by an internal rarefaction, it is left at liberty to act; and, in the latter case, is assisted by the internal expansion.

"The degree of propensity is in proportion to the diameter of the cheese. Therefore, in this point of view, broad vats are less eligible than narrow ones.

"There are, however, some strong reasons in favour of the present form of thin cheeses in these districts. If they were made narrower and of the same thickness, their number, and, of course, the labour and the requisite press room, would be greater. If their thickness were increased they would be more liable to rise, and would not be so soon ready for market, as they are at present: nor would they, perhaps, if made narrower, be so convenient to the dealers.

"To the consumer, however, the present form is extremely awkward, and the cause of unnecessary waste. It appears to me that, in regard to the convenience of the consumer, no cheese should be less than three or four inches thick; nor the diameter of cheeses of that thickness, more than ten or twelve inches.

"In North Wiltshire, we find the form of vats varying very much. The thin and the broad thick cheeses are still made in vats exactly of the Gloucestershire dimensions. But almost every dairy has vats of various forms and sizes; so that spare curd, a thing to be studiously avoided, is seldom heard of there.

"Vatting: With respect to the perfect closeness so much admired in the texture or substance of cheese, something may depend on the vatting; or rather, on the heat at which the curd goes into the press. If the common air, which is necessarily shut up, in greater or less quantity, with the curd, be, at the time of shutting up, in a state of rarefaction, it will, as it cools, condense; and, as it were, assist the press in giving the requisite compactness. Besides, curd, like wax, is softened by warmth; becomes pliable; and may be pressed into a closer, more uniform substance; than cold curd is capable of forming. The latter part of this position never struck me so forcibly, as in seeing the actual effect of heating curd very highly, in the instance of practice I saw in North Wiltshire.

"It is not an extraordinary circumstance for the cheeses to heave in the press: in which case, it seems, no weight is able to keep them down. They set men's laws at defiance. In this case, it is the practice of most dairywomen, I believe, to take it out; break it down small; and re-scald it. This, I understand, generally allays the commotion, so far as to prevent its rising in the press a second time.

"The weight of the press may be a thing of some importance, in the manufacturing of cheese. It seems to be a fact, sufficiently established, that net cheeses never heave; nor are found to be eyey; but are invariably close. I was assured, by an authority which I have no reason to doubt, that in Wiltshire, where (as has been already said) quantities of net cheeses are made for sale, it is no uncommon circumstance to form, out of the same cowl of curd, pressed cheeses which heave, and net cheeses which are perfectly close: it is farther remarked, in that observant district, that the heavier the press is, the greater propensity the cheeses have to heaving; and that filling the vats too full has a similar effect. These appear to me most interesting circumstances; and suggest a variety of theoretic ideas; which, however, it might be imprudent to risque on the present foundation.

"It may be unnecessary to observe, that an experimental enquiry into the art under consideration would be vague, without some method of identifying the subjects of experiment. Some permanent mark is requisite. Numbers are, perhaps, the best reference. In Norfolk, I made use of the numeral characters, cut out of plate iron. Common figures, of the same or other metal, would be still more simple. These lying upon the cheesing, while in the press, sink into the rind, and leave a lasting impression.

"The after-management of the cheese. Perhaps the principal improvement to be made in this stage of the art, is that of striking out some practical method of hastening the maturation of cheeses. Wine mixed with the curd brings on a rapid advance of ripeness. In Gloucestershire, I had an opportunity of observing the effect of three or four glasses of white wine thrown partially among the curd, during the operation of vatting. In a few months, the parts which had imbibed the wine, had passed the point of maturity, and were hastening down the stage of decay. Therefore, it is evident that, by composition, a species of ripeness

ness may be rapidly brought on; and the qualities of cheeses thus ripened, might, no doubt, be infinitely diversified. And, perhaps, by other means, the curd alone might be hastened to a more natural state of ripeness."

Mr. Marshall, in his Rural Economy of Yorkshire, says, "Skim-cheese (provincially, old-milk cheese) is the natural accompaniment of a butter dairy. In the richer parts of the Vale, towards the banks of the Rye, some new-milk cheeses are made: and of a quality nearly equal to those of Gloucestershire. But on the leaner parts of it, this species of cheese is seldom attempted."

"I have met with nothing striking in the manufacturing of skim-cheese to deserve notice; excepting what relates to the curd-mill; an utensil of the dairy which I never met with elsewhere, and which is new to this district."

"In making skim-cheese, the curd is broke up in the whey; the whey, when the curd has subsided, laded off; the remainder, with the curd, thrown into a coarse strainer; and having lain abroad in this (spread over a large tray, with a hole at the corner to let out the whey which drains off) until quite cool, the corners and loose part of the strainer are gathered together in the hand, and the curd squeezed as hard as the hands can press it. The curd in the strainer is then put into a vat, and set in the press for a few minutes to discharge the remaining whey more effectually. The whey having done running, the curd is taken out of the press, and re-broke as finely as possible, salted; and returned to the press."

CHEESE-LIP, a bag in which the dairy-women prepare and keep their rennet for making cheese. See **RUNNET**.

CHEESE-PRESS, a press used in dairies for squeezing the whey out of the cheese. We have given a drawing of the common cheese-press, on Plate VI. fig. 1. where A B is the press, C E, and F G, are levers moveable about the points D, E, F, G, by applying the hand at C; S is the stone or weight; and H the cheese to be pressed.

CHEESE-RENNET. See **YELLOW LADIES BED-STRAW**.

CHERRY-WINE, a very cooling and pleasant drink, made from the juice of cherries, properly fermented. The chief care necessary in making it, is to let the cherries hang upon the trees till they are thoroughly ripe, by which means their juice, which they yield in great abundance, will be the better perfected and enriched by the sun; to gather them in dry weather; press out their juice, and add a quantity of sugar proportioned to the strength you desire in the wine; for the more sugar there is added to the natural juice of the cherries, the stronger and richer the wine will prove, when of a proper age. When this is done, the whole must be regularly fermented, according to the method laid down under the article fermentation. See **FERMENTATION**.

CHEST, the breast, of that part of an animal's body which contains the heart, lungs, &c.

CHEST-FOUNDER, a distemper incident to horses, and occasioned by an improper treatment of an inflammation between the ribs. For if the inflammation be not dispersed in time, and the viscid blood and juices so attenuated by internal medicines, that a free circulation is obtained, such a stiffness and inactivity will remain on those parts as will not easily be removed; and this stiffness is generally called chest-founder.

The signs of this inflammation, are a stiffness of the body, shoulders, and fore-legs; attended sometimes with a short dry cough, &c. a shrinking when handled in those parts.

Bleeding, soft pectorals, attenuants, and gentle purges, are the internal remedies: and externally, the parts affected may be bathed with equal parts of spirit of sal ammoniac, and ointment of marshmallows, or oil of chamomile.

These outward inflammations frequently fall into the inside of the fore-leg, and sometimes near the shoulder; forming abscesses there, which terminate the disorder. *Bartlett's Farriery, p. 57.*

CHESNUT-TREE, the name of a tree, which well deserves the planter's care, affording excellent timber, and a very agreeable shade. It will grow to a very great size, and spread its branches finely on every side where it has room.

The leaves are large, and of a lucid green, and continue late in the autumn; nor are they so liable to be eaten by insects, as those of the oak; nor is there any better

food for deer, and many other animals, than the fruit of this tree.

Chesnut-trees are propagated by planting the nuts in February, in beds of fresh undunged earth. The best nuts for sowing, are such as are brought from Portugal and Spain, provided they are not kiln-dried, which is generally the case of those brought from abroad, to prevent their sprouting during their passage: if they cannot, therefore, be procured fresh from the tree, it will be much better to use those of the growth of England, which are full as good to sow for timber or beauty, as any of the foreign nuts, though their fruit is much smaller. The nuts should be preserved in sand, until the season for sowing, otherwise the mice and other vermin will soon destroy them. Before you set the nuts, it will be proper to put them into water, to try their goodness; which is known by their weight; such of them as swim upon the surface of the water should be rejected as good for nothing; but such as sink to the bottom, you may be sure are good.

In setting these nuts, the best way is to make a drill with a hoe, about four inches deep, in which you should place the nuts at about four inches distance, with their eye uppermost; then draw the earth over them with a rake, and make a second drill at about a foot distance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, in order to clear the beds, &c. When you have finished your plantation, you must be careful that it is not destroyed by mice, or other vermin: which is very often the case, if they are not prevented by traps, or other means.

In April these nuts will appear above ground; you must, therefore, observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery at a wider distance. The best season for transplanting these trees, is either in October, or the latter end of February; but October should be preferred. The distance these trees should have in the nursery, is three feet row from row, and one foot in the rows. If these trees have a downright tap-root, it should be cut off, especially if they are intended to be removed again; this will occasion their putting out lateral roots, and render them less subject to miscarry when they are removed for good.

The time generally allowed them in the nursery is three or four years, according to their growth; but the younger they are transplanted, the better they will succeed. Young trees of this sort are very apt to have crooked stems: but when they are transplanted out, and have room to grow, they will, as they increase in bulk, grow more upright, and their stems will become straight.

After they have remained three or four years in the nursery, they will be fit for transplanting where they are to remain: for the younger they are planted out the better they will succeed. But if they are propagated for timber, it is by much the better method to sow them in furrows, and let them remain unmoved: for these trees are apt to have a downright tap-root, which, being hurt by transplanting, often checks their upright growth, and causes them to shoot out into lateral branches.

If you design a large plantation of these trees for timber, after having two or three times ploughed the ground, the better to destroy the roots of weeds, you should make your furrows about six feet distance from one another; in which you should lay the nuts about ten inches apart, covering them with earth about two inches deep; and when they come up, you must carefully clear them from weeds. The distance allowed between each row is for the use of the horse-hoeing plough, which will dispatch a great deal of this work in a short time; but it should be performed with great care, so as not to injure the young plants; therefore the middle of the spaces only should be cleaned with this instrument, and a hand-hoe used to clean between the plants in the rows, and also on each side, where it will be unsafe for the plough to be drawn; and in hand-hoeing great care must be taken not to cut the tender rind of the plant. But for the two first years after sowing, it will be advisable to dig the ground each winter; because the plants will be too small to admit the hoeing-plough, and in summer to hand-hoe the ground.

When these have remained three or four years, you will, if the nuts have succeeded well, have many of these trees to remove; which should be done at the seasons before directed, leaving the trees at about three feet distance in the

the rows ; at which distance they may remain for three or four years more, when you should remove every other tree, to make room for the remaining, which will reduce the whole plantation to six feet square ; which will be sufficient for them, till they are large enough for poles, when you may fell every other tree, within a foot of the ground, in order to make stools for poles, which, in eight or ten years time, will be strong enough for making hoops, hop-poles, &c. for which purposes they are preferable to most other trees ; so that every tenth year here will be a fresh crop, which will pay the rent of the land, and all other incidental charges, and, at the same time, a full crop of growing timber left upon the ground.

Chestnut-trees were formerly much cultivated in England, and doubtless produced good profit to the owners ; for the wood of this tree is equal in value to the best oak, and, for many purposes, far better : particularly for making vessels to hold all kinds of liquor, it having the property, when once thoroughly seasoned, of maintaining its bulk constantly ; and is not, like other timber, apt to shrink or swell ; and hence all the large casks, tuns, &c. for wines in Italy, are made of this timber, as being preferred by the inhabitants to any other timber whatsoever. It is also very valuable for pipes to convey water under ground, as enduring longer than the elm, or any other wood. In Italy it is planted for coppice-wood, and is much cultivated in stools, to make stakes for supporting their vines, as it will endure seven years, which is near double the time any other stakes will do. *Miller's Gard. Dict.*

CHEWING BALLS, the name of a medicine adapted to restore a lost appetite, an infirmity which horses are often subject to, proceeding from a salt humour, and a bitter phlegm, which obstructs the passage of the throat, and makes them loath their food.

These balls are made in the following manner : Take a pound of assa-fœtida, as much liver of antimony ; half a pound of the wood of bay-tree ; an equal quantity of juniper-wood ; and two ounces of pellitory of Spain : pound all these ingredients apart into a gross powder, in order to which the woods must be previously well dried. Then put them all together into a mortar, and incorporate them with a sufficient quantity of good verjuice, well clarified, pouring it in by degrees, till the whole is reduced to an uniform mass. Make the whole into balls of an ounce and a half each, and dry them in the sun. Wrap one of these balls in a linen-cloth, and fastening a thread thereto, make the horse chew it for two hours in the morning, and he will eat as soon as you take off the bridle ; do the same at night, and continue this method till the horse recovers his appetite. When one ball is consumed, put in another.

These balls may be used on the road, as you travel, being fastened to the bit of the bridle.

CHICKLING-vetch, called by gardeners, the common everlasting pea, and by C. Bauhine, *lathyrus latifolius*, a perennial plant growing naturally in many parts of England.

A correspondent of the editors of the Museum Rusticum recommends this plant as well deserving cultivation for the food of cattle, as the root, which will grow in almost every soil, yields every year a great burden of excellent provender.

"I sowed, says this gentleman, three years ago, a rood of land, light, and but poor in quality, with this seed : the work was done early in the spring, the land being prepared as for barley.

"I sowed it not in the broad-cast way, as I should have found it much more difficult to keep down the weeds ; but I caused a slight furrow to be drawn the length of the land, with a light plough : and when the seed was thinly sprinkled, or rather dropped into this, another was drawn at a foot distance, in which the seed was dropped in the same manner.

"An interval, or fallow space, was then left at least two feet wide : and then two more rows of the vetches, till the whole land was sown. I must observe, that I covered the seed by means of a light harrow with wooden tines, drawn backward and forward across the land.

"When the plants came up, I had them well hoed to clear the ground of weeds ; and when they grew a little strong, they were set out with the hoe to about a foot distance in the rows, that they might have room to spread and branch.

"The first year they yielded no great quantity of fodder, but they have since made me ample amends.

"The second spring they came up very strong and vigorous, branching out much ; and when I turned a couple of horses in to feed, they were very fond of it, eating it very greedily, though they were taken out of a good natural upland pasture.

"The last summer the land was almost entirely covered, and it yielded a great deal of seed indeed ; for experiment sake, I caused a few roods to be mowed just before it flowered, and it made good hay, sweet, and without being sticky.

"I therefore think, from my little experience in the matter, I have some foundation for recommending this plant to the notice of the public. I could wish, indeed, I had been more accurate in my experiment ; but what is past cannot be recalled ; and some other person may, perhaps, hereafter, give the public more useful information on this head."

CHICKWEED, called by botanists *cucubalus*, flowers early in the spring, and, if it be suffered to grow, several times in the course of the year. The way to destroy it, is therefore to pluck it up from time to time, before it can shed its seed.

The berry-bearing sort, which grows with smooth erect stalks, globular empalements, and stamina longer than the petals, is the wild lychnis, or white behen of the shops. This is a very rambling weed, natural to most parts of England, and is frequently called spatling poppy. Its roots are perennial, and strike so deep into the earth, that they are not easily destroyed by the plough ; for which reason, bunches of this plant are too common among corn, in land which has not been perfectly well tilled. Summer fallows, and carefully harrowing out every part of the roots, which should then be burnt, will here prove the best and most effectual remedy.

CHICKWEED is also the name of an annual weed, called by botanists *alsine*. This weed, though it perishes every year, will soon become very troublesome, if suffered to stand till it sheds its seeds, which Mr. Lisle thinks it will do several times in the year ; for he observed, on the 23d of October, a great deal of this weed, the branches of which carried many buds of blossoms, many flowers full blown, and many pods with white seeds almost ripe : so that its increase may be the less guarded against by any sort of husbandry in the common way. The repeated hoeings in the new husbandry must here be of singular advantage ; and, at all events, particular care should be taken to prevent the seeding of this plant upon dung-hills, where it is too often suffered to grow unnoticed and undisturbed : for its seeds scattered there, and intermixed with the dung, will soon give birth to a multitude of weeds in the land upon which it is spread ; unless it be kept, as indeed all dung used for manure ought to be, till it is thoroughly rotted, and the seeds have lost their vegetative power.

CHICORUM IN FIBUS. See SUCCORY.

To CHISSUM, to put forth roots, to grow.

To CHITT, to sprout out, to grow.

CHITTED, sprouted, shot out, grown.

CHIZZLE, bran, the husky parts of ground work.

CHOCY, the same with chalky, resembling chalk, mixed with chalk, or of the nature of chalk.

CHOLIC. See GRIPES.

CHURN, the name of the vessel in which the cream is coagulated by agitation.

There are two sorts of churns, one called the common or Dutch churn, the other the barrel churn.

The common churn is represented on Plate VI. fig. 2, 3. where fig. 2. is the arbor or staff ; and fig. 3. the body of the churn. The lower end of the staff is placed in the body of the churn, and being raised with a pretty quick motion by the hand on the upper part of the staff, the cream in the body is agitated, and by that means coagulated into butter.

Fig. 4, 5, 6, 7, represents the several parts of the barrel-churn.

Fig. 4. is the arbor of the barrel-churn. Fig. 5. its bung, or cover. Fig. 6. the body of the churn ; and fig. 7. the stand on which it is placed. The arbor cannot be taken out of the body of the barrel-churn, without the help of the cooper ; but is here represented by itself, to shew the manner in which it is made. In fig. 6. the churn is represented with the arbor on it, but not placed on its stand, in order to shew the latter. When the utensil is to be used, the churn is placed upon its stand, the cream poured into it through the bung-hole, and the hole closed

with its bung. The arbor is then turned round pretty fast, by which the four leaves of the arbor agitate the cream, and coagulate it into butter. *See the articles DAIRY and BUTTER.*

CIBOULLES, a sort of small onions, propagated only by seeds, which, if sown in March, will be ripe in August; and these are reckoned the best for keeping; but they may be sown in almost every season. They differ from the onions, of which they are probably a degeneracy, in that they do not form bulbs at their roots, but shoot out several upright blades, and those which produce the greatest number of these, are reckoned the best.

Their culture is the same with that of onions, like which they must be thinned, and well weeded. They will increase greatly, even in very dry summers, if they have been transplanted into beds of good earth, and those beds are kept well watered. The reddest, hardest, and mildest, are the most esteemed.

CIDER, or CYDER. *See the article CYDER.*

CLASPERS, the threads or tendrils of creeping plants.

CLAVER, a word used in some counties of England for clover. *See CLOVER.*

CLAW, the foot of a beast or bird, armed with sharp nails.

CLAY, an unctuous and tenacious earth, justly accounted the stiffest of all soils.

Clays are of different sorts, and of as different colours. One kind of them is so obstinate, that scarce any thing will subdue it; and another so hungry, as not to be satiated without uncommon pains, because it absorbs whatever is applied, and turns it to as bad a clay as itself. Some clays are fatter than others, some more slippery; all of them tenacious of water on the surface, where it stagnates and chills the plants, without penetrating the soil; and in dry seasons they harden with the sun and wind, are very barren, and extremely untractable. The closeness of clay hinders plants from extending their roots to search for their necessary food, and prevents the entrance of water, which would help to convey it to them.

The more unctuous and fat clay frequently lies upon the other, and has often a bed of chalk beneath it: but neither is worth any thing till loosened, and fitted to admit the influence of the sun, air, frost, &c. The blue, white, and red clay, if strong, are all unkind: the stony and looser sort is sometimes tolerable; and the light brick earth does very well with most fruit-trees.

Clay, in general, of whatever kind it be, is of all earths the very worst for vegetation: yet even this, as well as any other untoward soil, may, with industry and proper correctives, be made to produce roots and plants which require the lightest and hollowest mould.

Among all the manures for clay, sea-sand claims the preference, founded upon experience, as best suited to break its too great cohesion. Dr. Cox has given us a very accurate account of the sea-sand used by the farmers of Cornwall, by which the lands are greatly benefited, and their crops largely increased. Doubtless the husbandmen of other parts of the kingdom, whose lands lie within a moderate distance of the sea, might find the same advantage from using the same manure, which many of them are too apt to overlook.

"The sea-sand made use of in the agriculture of Cornwall," says that ingenious gentleman, "lies commonly at or near the shore. To distinguish it from what is useless, it is proper to observe, that this sand is formed by the grating of stones, shells, &c. rolled and tumbled over by the wash of the sea. If the matter be shelly, as it is called, that is, the particles formed by the rubbing of stones only, it is of small value: but if it be tolerably shelly, it is the thing desired. Of this shelly sand there are three colours. About Plymouth, and the southern coast, it is blueish, or grey, like ashes, which I conceive to be from the breaking of muscles chiefly, and oyster-shells mixed with it. Westward, near the Land's-end, the sand is very white, and in Scilly glittering. This I think comes from the mouldering of moor-stones, or a kind of free-stone, mingled with the white shells of the scallop-fish. On the north-sea about Padstow, and eastward of Lundy, the sand is rich, of a reddish-brown colour tinged with yellow, and consists chiefly of the broken shells of cockles; which I guess to be of that colour there, from the wash of the Severn, which falls very dirty into the Severn-sea.

"Besides these differences in the colour of the sand, there is also another in the bigness of the grain. The

small is reckoned best for the tenant who takes to tillage only for four years; because it works soonest, and yields the most speedy return. The larger grain is thought to be more profitable for the landlord, because it abides longer in the ground, and makes the pasture afterwards the richer.

"In Falmouth Haven, near St. Mawe's Castle, there is a sort of sand, or rather coralline, that lies about a foot under the ooze; which ooze being removed, and the bed opened, this sand is taken up by a dredge, and is used about Truro, Probus, &c.

"West of the mount, in Portcuthnoe-cove, is a large shelly sand. In White-sand Bay, and about St. Ives, it is very white and small.

"About Minver, Perinsand, and Lelant, the sands are frequently blown up by the wind, and cover abundance of good land. Some houses and even churches have been buried in it; nor has any method hitherto discovered been able to prevent its devastation.

"Of all these sands, the best are accounted, as to colour, first the reddish, next the blue, then the white. As to kinds, the most shelly, and the coralline, are the best, especially if it be taken up from under the salt-water, either by dredges, or being left almost dry by the ebbing of the tide. The blown sand is accounted of no use: and, in general, if sand be only well drained of salt-water, so that it can be conveniently carried, it is better than that which has lain long drying in the sun and wind, which takes off much of its virtue.

"These useful sands are carried by lighters as far up into the country as the tides will serve for that purpose, and there they are cast on shore. From thence they are fetched, in some places, by wheel-carriages; but in most, by reason of the hilliness, narrowness, and badness of the ways, on horseback; one horse carrying about thirteen or fourteen gallons. One man drives seven or eight of these horses, tailed together, to the distance of nine or ten miles from the sand-place; and each horse-load comes to about eight-pence or nine-pence, in some places; though not so much in others: for where it is dredged out of the sea, it costs but twelve or thirteen shillings the lighter, containing six score horse-loads, at the landing-quay, or sand-place; and where it is loaded from the dry-beach, after the ebb, it is not above four shillings the lighter, exclusive of the land-carriage, which is computed at about thirty-two thousand pounds a year, in the whole of that country.

"When this sand is brought home, it is spread on the ground intended for wheat; or usually in the first crop of four, whatever be the grain. For after four crops, the Cornish farmers generally leave their land to pasture for six or seven years, before they till it again: and indeed the grass is so good, immediately after tillage, that they commonly mow it the first year, and which they call mowing of gratten.

"The Cornish acre contains eight-score yards, of eighteen feet to the yard. On one of these acres, if near the sand-place, good husbandmen bestow three hundred sacks, or horse-loads: if within the reach of three turns a-day, two hundred: if within two turns, one hundred and fifty: where only one turn can be made, eighty or an hundred; and so in proportion at greater distances, even to twenty or thirty sacks on an acre rather than none.

"The effect generally is, that where much sand is used, the seed is as much as the straw little. Land thus manured has produced barley, of which the ear has been as long as the stalk it grew on. But where less sand is used, there is but little, and that little hungry grain." *Phil. Transact.* N^o 113.

Where this excellent manure is found, it is taken up by a large bag of the strongest canvas, to the mouth of which is fixed an iron hoop, or frame, to keep it open, and sink it to the bottom of the sea, that it may take up the sand and coral, as it is dragged along by the bargemen. The Rev. Mr. Borlace says, that a barge-load, which is usually delivered for ten shillings, or less, if near the place of dredging, will dress an acre, provided the land be tolerably good.

Large quantities of this shelly sand lie neglected on most of the coasts of England. The benefits arising from it, particularly when laid on clayey grounds, are indeed somewhat slow, but they are very lasting. The improvement is not the first or second year; because this manure consists of hard bodies, such as the sand itself, shells, fragments of coral,

coral, and other calcareous substances, which require time to dissolve them, and which afterwards enrich the land for many years. The best is that which is mixed with coral, and other hard substances of that kind. It gives the heat of lime, and the fatness of oil, to the land it is laid upon. Being more solid than shells, it contains a greater quantity of fermenting particles in an equal bulk; nor does it dissolve into the ground so soon as shells, but decaying more gradually, continues longer to impart its warmth to the juices of the earth.

Similar to this is the practice in Ireland, in that part of the bay of Londonderry, called Loughfoil, towards the eastern side of which lie several banks, about the level of low water. They are formed of the shells of several sorts of sea-fish, particularly periwinkles, cockles, limpets, &c. The country people go thither with boats, and take loads of these shells, which they leave in heaps on the shore, till they are well drained, and thereby rendered lighter for farther carriage. They then carry them in boats as far as the river will allow, and afterwards in sacks on horses, six, seven, or more miles up in the country. They allow sometimes forty, but more commonly eighty barrels to an acre. These shells agree with boggy, heathy, clayey, wet, or stiff land, but not with sandy. They seem to give the land a sort of ferment, as yeast does to bread, opening and loosening the clods, and by that means making way for the roots to penetrate, and the moisture to enter into the fibres of the roots. This manure continues so long, that the archbishop of Dublin, from whom this was communicated to the Royal Society, could not find any person able to determine the time of its duration.

The reason of its long continuance seems to be, that the shells melt every year a little, till they are all spent, which requires a considerable time; whereas lime, &c. operates, in a manner, at once. But it is to be observed, that, in six or seven years, the ground becomes so mellow, that the corn which grows on it cannot support itself, and the land itself must be suffered to lie a year or two, that the ferment may be a little quieted, and the clods harden; after which it will bear as long again, and continue so to do, with the like intermission, for twenty or thirty years.

The good and lasting effects of shelly sand, for the improvement of clay, afford a strong presumption that there is an acid in the clay, which the shells absorb or correct: for when that acid is removed, the clay becomes more easily soluble, or miscible with water, or, as the farmers term it, is rendered mellow. This is contrary to the opinion of a very ingenious gentleman, Dr. Home, who because he could not separate an acid from clay, concluded that there was none in it. That the first object in the improvement of clay is the destroying of this acid, is pretty evident from the qualities of all the substances useful for this purpose; every one of them being of the calcareous kind. The tenacity of clay does not seem to be owing to the smallness and unctuous smoothness of its particles; for in this some marles exceed it, and yet are perfectly and easily soluble in water, probably because they are of a calcareous nature: and if clay be rendered in some degree calcareous, by the addition of alkaline or calcareous substances, so long as it continues in that state, it is said to be mellow; that is, it is soluble like marle, and continues fit for the production of plants, till the acid in the air either neutralizes the alkali, or so far impregnates the calcareous substances, that they can no longer attract the acid. If this be fact, as it seems to be, common sand can be of little use; because the clay will cling as close to a stone, or grain of sand, as it would to part of itself, if the stone, or sand does not so far change the body of the clay, as to take off its tenacity; and therefore Dr. Cox seems to be very right in saying, that the sand which is formed by the grating of stones only, is of little use as a manure. However, as some eminent writers on this subject strongly recommended sand in general, though they all agree in giving the preference to sea-sand, it may not be amiss to hear what they have said on the subject.

Columella, speaking in general terms, says, that his uncle used to carry sand on clay, and, on the contrary, bring clay on sandy grounds, with good success.

Mr. Worlidge says, that the best sand for fertility is that which is washed from hills or other sandy places by the violence of rain; and that sands which are dry have little fertility in them. *Systema Agriculturae*, p. 67.

Mr. Bradley, after dividing sand into two general sorts, as Dr. Lister does, viz. the soft, round grained sand, such as is found in bogs and hills; and the sharp or rag-

sand, as it is commonly called; taken from the bottom of rivers, the sides of high-ways, or the sea; advises laying even the former on heavy soils, especially if it happens to be mixed, as it sometimes is, with rotted vegetables or animal substances; to which he adds, that its efficacy will be increased by the addition of sand of a sharper nature, about a load of which last, if used alone, should be spread upon every rood of very stiff land; for a sufficient quantity of it must be allowed, or else the clay will soon overcome it. *Complete Body of Husbandry*, p. 84.

“The use of sand, says Mr. Miller, is to make the clayey earth fertile, and fit to feed vegetables, &c. for earth alone is apt to coalesce, and gather into a hard coherent mass, as is apparent in clay; and earth thus glued, as it were, together, is no way disposed to nourish vegetables: but if the sand, &c. that is, hard crystals, which are not dissolvable in water, and still retain their figure, be intermixed with such earth, they will keep its pores open, and the soil loose and incompact, by which means the juices will circulate, and plants are nourished thereby. By means of sand, the earth is rendered, in a manner, organical; pores and interstices being thereby maintained, somewhat analogous to vessels, by which the juices may be conveyed, prepared, digested, circulated, and at length excreted, and thrown off into the roots of plants.” *Miller's Gard. Dict.*

Small gretty gravel operates in nearly the same manner, as an opener of the earth, and is strongly recommended by Mr. Evelyn, Mr. Worlidge, Mr. Bradley, and Mr. King. Good crops have been produced by very stiff and sour land, after it has been manured with gravel, which, to fit it for this purpose, should be screened, or sifted, so as to leave among it as few stones as possible.

Shell-marle, or any marle, which makes a strong effervescence when an acid is dropped upon it, is a particularly good manure for clay; because dissolving easily in water, it gives a sufficiently free passage to this fluid, by which means the clay is kept dry even in winter: and if the soil be of a cold sour nature, the absorbent quality of the marle destroys that mineral acid, and keeps the ground warm.

The fossil-shells which has been found in some countries at a great distance from the sea, are a good manure, if they still retain their quality of shells: but besides their being generally petrified, they never are so serviceable as those which are taken from the sea-shore.

All animal and vegetable substances are likewise proper manures for clay. See the article MANURE.

The alkaline quality of the ashes of all vegetables, and the calcareous quality of coal-ashes, render them singularly beneficial to stiff and sour land, for which purpose they are successfully used in the neighbourhood of some great cities where coal is burnt for fuel. They open clayey grounds, and correct their bad qualities. The gardeners and farmers about London know their value, and make a very profitable use of them, particularly to bring into order those grounds which have been dug for brick-earth. After spreading these ashes upon the clay-bottom, they either sow horse-beans, or set the early Spanish, or, sometimes, the Windsor-bean, in those spots; or else they lay such lands down with rye-grass, which generally succeeds very well. Mr. Bradley, blaming the people of Staffordshire, and the counties adjoining, where there are coal-pits, for not improving their many heavy grounds around those pits, by manuring them with coal-ashes, which might easily be burned out of the waste-coal, says, “That wherever there are plenty of coal-pits, there can be no want of good profitable land.” On the same principle, we may account for the effects of the calcination of earth, commonly called, burn-baking, or Devonshiring. See the article BURN-BAKING.

Lime, as it is generally used, is not found to be of so great service in the improvement of clay, as a long established practice might give room to think, or its qualities reason to expect; because its particles are so extremely small, that when separated, or mixed with the clay, they soon become part of its body, and, being so much divided, are speedily saturated by the acid, either in the clay, or in the air: the best method therefore, of using lime as a manure for clay is, to spread the lime-stone unburnt; in which original state acids effervesce strongly with it, and therefore it will be likely most effectually to mellow the clay. It is likewise, in this its natural state, attended with the farther advantage of saving the expence of burning, and becomes a

very

very lasting manure; nay, probably a perpetual one, if the stones are broke into small pieces, which is the proper method of using it; as is practised at Hornton in Oxfordshire, where they manure their land with a sort of stone, common in those parts; and about Devonshire, where a kind of red rock, very tender, and easily broken into sand, is found to be of extraordinary service to clay, or other stiff soils: for any soft stone, broken small, will be of advantage to cold lands, if laid upon them. We find by Pliny, that lime was used as a manure by the ancient Britons, whose lands were thereby rendered extremely fertile.

Mr. Evelyn advises using lime a little slacked for cold wet grounds, and stiff clays; and observes, that it is apt to over-heat dry soils.

Chalk operates in nearly the same manner as lime: but, as Mr. Lisle justly remarks, it if be laid on clay, it will in time be lost, and the ground will return again to its former condition of clay; as we have already mentioned under the article chalk. See CHALK.

Soft pure clay contains a large proportion of very fine particles, more perhaps than any soil usually cultivated by farmers, as may be discovered by dissolving them in water, and after being well mixed, suffering them to subside, which they do in a longer or shorter time, in proportion to the fineness of their parts. In making this experiment it is found, that the finer parts of clay remain suspended in the water for many days, being nearly of the same specific gravity as the water. When they are subsided, and the water suffered to evaporate, the clayey particles unite again, and cohere as strongly as before. This strong cohesion of the parts of clay, is the cause that the roots of strong plants penetrate the clayey soils with difficulty, and that weak roots cannot penetrate such soils at all. Horse-beans for example, which have strong roots do, with some assistance of manures, make their way into strong clays, while the weak rooting carrot is entirely shut out, and starves in the soil that furnishes abundance of nourishment to beans. Clay planted with weak rooting plants appears to be a barren earth; but when clay is opened, and impregnated by the influences of the atmosphere, it becomes a rich pasture for plants: so that it may be said that land is more or less fertile in proportion to the quantity of clay it contains; or which is nearly the same, in proportion to the quantity of very fine parts in it.

As the separating or dividing the fine particles of clay, is the principal means of rendering it fertile, there are several mixtures or manures, adapted to break the strong cohesion of the clayey particles, and these act in different manners, but to all the purpose of disuniting the particles of the clay.

1. Dung, and other putrescent manures, are great enrichers of clay; they open the clay by fermentation, which is a very powerful agent; but the action of these manures is of short duration, and when the fermentation ceases, the clay returns again to its former state of cohesion.

2. Sand of various kinds, which though of so hard a quality as not to furnish any fertile matter to the clay, yet by insinuating into it, and dividing the fine parts of the clay, renders it susceptible of the riches contained in the air or atmosphere.

3. Chalk, which is a body consisting also of very fine parts; and these appear to have one quality in them, that adapts them in a particular manner to open, and keep open the particles of clay; for chalk is of a very dry nature, and the parts, when once separated, appear to have a repulsive quality, and do not, as clay, unite: again, in this seems to consist chiefly the great benefit of chalk, as a manure to clayey land. Chalk, by dividing and keeping open the fine parts of the clay, not only admits the fertilizing influences of the air to enter into it, but likewise makes way for the superfluous moisture of the clay to run off, which was the cause of that coldness in clayey land, which is unfavourable to vegetation: this is confirmed by experience: clays, when opened, become drier and warmer, and produce their crops earlier than they did before.

Other calcareous bodies have, in some degree, the same effects upon clays as chalk; and those kinds of marl that contain the greatest proportion of calcareous earth in them, are the most proper to be laid on clays.

Frost is a most powerful pulveriser of clays when they are dry: in order to receive the greatest benefit by frost, the clayey land should be ploughed up in autumn, or begin-

ning of winter; and not harrowed, but suffered to remain rough during the winter: in this state sand or chalk should be laid upon it. The frost will penetrate the clods exposed to it on all sides, and as soon as the frost breaks they will fall down fine by harrowing, which will mix the chalk with the soil; and if at the same time the land is dressed with dung, warm compost, or such other warm putrescent manure as can be spared, and harrowed in with the chalk, these will lay the foundation of a lasting improvement.

CLAYEY, mixed with clay, partaking of the nature of clay.

CLAY-LANDS, such as partake of the nature of clay.

See the article CLAY.

The natural produce of clay-lands, with regard to weeds, is goose-grass, or wild-tansy, large daisies, thistles, docks, May-weed, poppies, &c.

CLEARING, a term used in threshing corn, to signify a heap large enough to winnow.

CLEDGY, stiff, stubborn, hard, tenacious, mixed with clay.

CLETC, a brood, as of chickens, &c.

CLOD, a lump of earth or clay.

CLODDING-BEETLE, a large beetle used in some parts of England for breaking the clods. This operation may be much sooner performed, and at far less expence, by the spikey-roller. See the article SPIKEY-ROLLER.

CLOVER, the name of a well known plant, and of which there are a great variety of species; but only three of them are cultivated in the open fields for the food of cattle. viz. the red Dutch clover, the white Dutch clover; and the hop-clover.

The first sort is sufficiently known in England by the name of red clover, and therefore needs no description. It is called by Linnæus, *Trifolium caule erecto, foliis oblongo-ovatis integerrimis, spicis ovatis, clypeibus setaceis*.

Since red-clover has been cultivated in England, great improvements have been made in clay-lands, which before produced little except rye-grass, and other coarse bents; but, being sown with red-clover, have produced more than six times the quantity of fodder they formerly did: whereby the farmers have been enabled to feed a much greater stock of cattle, than they could do before, with the same extent of ground, which has, at the same time, enriched the soil, and prepared it for corn; and hence it is now common, where the land is kept in tillage, to lay down their ground with clover, after having had two crops of corn, whereby there is a constant rotation of wheat, barley, clover, or turnips, on the same land. The clover-seed is generally sown with the barley in the spring; and when the barley is taken off, the clover spreads and covers the ground; and this remains two years, after which the land is ploughed again for corn.

Clover is a biennial plant, whose roots decay after they have produced seeds; but by eating it down, or mowing it, when it begins to flower, it causes the roots to send out new shoots, whereby the plant is continued longer than it would naturally do. The common allowance of seed for an acre of ground is ten pounds. In the choice of the seed, that which is of a bright yellow colour, inclining to brown, should be preferred; and the pale coloured thin seed should be rejected. The clover-seed should be sown after the barley is harrowed in, otherwise it will be buried too deep; and after the seeds are sown, the ground should be rolled, which will press the seeds into the ground; but this should be done in dry weather, for moisture will often cause the seeds to burst; and when the ground is wet, the seeds will stick to the roller. The above is the method generally practised by most people, in sowing this seed with corn; but it will be much better if sown alone; for the corn prevents the growth of the plants till it is mowed and taken off the ground, so that one whole season is lost; and many times, if there be a great crop of corn upon the ground, it spoils the clover so that it is hardly worth standing; whereas, when it is sown without any other seed, the plants will come up more equal, and come on much faster than that which was sown the spring before under corn.

It is therefore advisable to sow the seed in August, when there is a prospect of rain soon after; for as the ground is, at that season, warm, so the first shower of rain will bring up the plants, and these will have time enough to get strength before winter: and if the clover be well rolled

rolled some time in October, when the ground is not too wet, it will press the ground close to the roots, and cause the plants to send out more shoots: the same should be repeated in March, which will be found very serviceable to the clover. The reason for preferring this season rather than the spring, for sowing the seeds, is, because the ground is cold and wet in spring, and if much rain falls after the seeds are sown, they will rot in the ground; and many times when the seed is sown late in the spring, if the season should prove dry, the seeds will not grow. The other season is therefore the surest, and consequently should be preferred.

The most usual time, however, of sowing the red or broad clover, is in the spring; for though it will come up well if sown in autumn, it is, while young, very liable to be killed by frost; and many crops of it that have come up finely in autumn, have been totally destroyed by the frost in winter; especially in strong moist soils, upon which it commonly produces the greatest crops, if sown in the spring.

About the middle of May this grass will be fit to cut, when the greatest care should be taken in the making it into hay; for it will require a great deal more labour and time to dry than common grass, and will shrink into less compass; but if it be not too rank, it will make extraordinary rich food for cattle. The time for cutting is, when it begins to flower; for if it stands much longer, the lower part of the stems, and the under leaves will begin to dry, whereby it will afford a less quantity of hay, and that not so well flavoured.

Some people cut three crops in one year of this grass, but the best way is to cut only one in the spring, and feed it the remaining part of the year, whereby the land will be enriched, and the grass will grow much stronger.

One acre of this plant will feed as many cattle as four or five acres of common grass; but great care should be taken of the cattle when they are first put into it, lest it fill them with wind and kill them, which is called their being hoven. See the article HOVEN.

In order to prevent this accident some turn them in for a few hours only at first, and so stint them as to quantity; and this by degrees, letting them at first feed one hour only in the middle of the day, when there is no moisture upon the grass, and so every day suffer them to remain a longer time, until they are fully seasoned to it: but great care should be taken never to turn them into this food in wet weather; or if they have for some time been accustomed to this food, it will be at least proper to turn them out at night in wet weather, and let them have hay, which will prevent the bad consequences of the green clover. Others give their cattle straw while they are feeding upon the grass, to prevent the ill effects of it; but this must not be given them in the field, because they will not eat it, where there is plenty of better food. There are others who sow rye-grass among their clover, which they let grow together, in order to prevent the ill consequences of the cattle feeding wholly on clover; but this is not a commendable method, because the rye-grass will greatly injure the clover in its growth, and the seeds will scatter, and fill the ground with bent.

When the seeds are intended to be saved, the first crop in the spring should be permitted to stand until the seeds are ripe, which may be known by the stalks and heads changing to a brown colour, when it should be cut in a dry time; and after being well dried, it may be housed till winter, when the seeds should be threshed out; but if the seeds are wanted for immediate sowing, it may be threshed before it be housed or flacked; but it must then be well dried in the field, otherwise the seeds will not quit their husks.

It has been a common complaint among the farmers, that they could not thresh out these seeds, without great labour and difficulty; but this is chiefly owing to their cutting their spring crop, when it begins to flower, and leaving the second crop for seed; which ripening so late in autumn, there is not heat enough to dry the husks sufficiently, whereby they are tough, and the seeds rendered difficult to get out. This complaint may therefore be entirely removed by leaving the first crop for seed, as above directed; and then the ground will be ready to plough and prepare for wheat the same year, which is another advantage.

When cattle are fed with this hay, the best way is to put it in racks, otherwise they will tread a great deal of it down with their feet. This feed is better for most other cattle than milch cows; so that these should have very little of it, lest it should prove hurtful to them; though it is not near so injurious to any sort of cattle when dry, as it is when green.

The second sort, namely, the white Dutch clover, grows naturally in most of the pastures in England; and is generally known among the country people by the name of white honey-suckle. Linnæus calls it *Trifolium capitulis umbellaribus leguminibus tetraspermis, caule repente*.

This is an abiding plant, whose branches trail upon the ground, and send out roots from every joint, so that it thickens and makes the closest sward of any of the sown grasses; and it is the sweetest feed for all sorts of cattle yet known: therefore when land is designed to be laid down for pasture, with intent to continue so; it should be sown with the seeds of this plant.

There is an advantage of pasturing white clover, which does not strike every farmer: each joint of them furnishes a fresh root, (and of course a fresh plant) whenever such joint comes in close contact with the soil; and consequently the more it is trodden, the thicker it will get upon the ground. Mr. Marshall recommends the cutting of clover in the beginning of June, before the middle; be there much or little; as cutting it while in full vegetation, no doubt, makes it branch: or; if thin, top it in May, and mow only once.

The usual allowance of this feed is eight pounds to one acre of land; but this should never be sown with corn, for if there is a crop of corn, the grass will be so weak under it; as to be scarce worth standing; but such is the covetousness of most farmers, that they will not be prevailed on to alter their old custom of laying down their grounds with a crop of corn, though they lose twice the value of their corn by the pooriness of the grass, which will never come to a good sward, and one whole season is also lost; for if this feed is sown in the spring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than the grass which is sown with corn will produce the second year. The seed of this sort may also be sown in autumn; in the manner before directed for the common red clover; and this autumnal sowing, if the seeds grow kindly, will afford a good early crop of hay the following spring; and if, after the hay is taken off the land, the ground be well rolled, it will cause the clover to mat close under the ground, and become a thick sward.

The seeds of this white Dutch clover is annually imported from Flanders, by way of Holland, whence it received the name of Dutch clover: not that it is more a native of that country than of this, for it is very common in moist pastures, in every county in England: but the seeds were never collected for sowing in this country till of late years; nor are there many persons here, even now, who save this seed; though it may be done if the same method as is practised for the red clover be taken with this sort: it should therefore be recommended to every farmer, who is desirous of improving his land, to sow carefully an acre or two of this white clover for seed, which will save him the expence of buying for some years, when the price is great; and there will be a sure market for any quantity he may have to spare.

The reader will find a farther account of this grass under the article PASTURE.

The third sort, namely hop-clover, called by some yellow meadow trefoil, and by botanists, *Trifolium spicis ovalibus imbricatis, vexillis deflexis persistentibus, calycibus nudis, caule erecto*, grows naturally among the grass in the upland pastures of this country; but the seeds are frequently sold in the shops, and are by many mixed with the other sorts of clover and grass-seeds, for laying down ground to pasture. This plant grows with upright branching stalks about a foot high, garnished with trifoliate leaves, whose lobes are oblong and heart-shaped, but reversed, the narrow point joining the foot-stalks. The flowers, which are yellow, grow from the wings of the stalk, upon long foot-stalks, collected into oval imbricated heads, having naked impalements lying over each other like scales, somewhat like the flowers of hops, from whence the plant had the name of hop-clover. But there are two sorts of this

clover, which grow naturally in England. The other is a much smaller plant than this, and generally known by the name of none-such, or yellow hop trefoil. See the article NONE-SUCH.

The hop-clover is strongly recommended by the following circumstances. 1. It not only grows, but flourishes on the most barren sands, and therefore must be a very proper grass to cultivate on such unfertile soils, where any other grass that is worth notice will not grow at all. 2. It is not apt to swell cattle as the red clover does. 3. In good ground it will continue long, and bear a very good feed or crop, as Mr. Tull, though prejudiced against clovers, confesses; and, by its flourishing both on sands and clay, which have not been ploughed for many years, it seems likely to continue long in any soil.

CLOUGH, a valley between two steep hills. It also signifies a cliff.

CLOUT, an iron plate on the axle-tree of a carriage.

CLUMP, a number of trees growing together without shape or order.

CLUNG, closed up, or stopped; spoken of hens when they do not lay. It is also applied to wood, or any other thing that is shrivelled, or shrunk up, when it is said to be clung.

CLUSTER, a bunch, a number of things of the same kind growing or joined together. Also a number of animals, or a body of people collected together.

M. de Chateauxvieux has made a very remarkable experiment on sowing corn in clusters, which must not be omitted here.

"It is of great consequence, says that ingenious and assiduous cultivator, to know which is the most profitable way of sowing beds with corn; I mean, that by which they will be stocked with a proper number of plants; for when too much seed is sown, the plants hurt one another; and when too little, the earth is not enabled to produce so much as it is capable of doing.

"The business therefore is to determine what number of plants would be most advantageous. Luckily the difference is wide enough between the too great, and the too small number; and the produce of the crop can only be diminished by an excess one way or the other.

"But whatever certainty we may acquire with respect to this interesting point, we cannot flatter ourselves that we shall be always able to keep it in our practice. The various accidents to which corn is liable, from the hour of its being sown till it is reaped, will always frustrate the methodical arrangement which we may have intended to give the plants.

"The difficulty of succeeding in this enquiry ought not however to discourage us; for it would be attended with such advantage, as would make very ample amends for all the labour bestowed upon it. Let us then have recourse to experiments. Those that are made with this view can never be quite useless. If they do not lead us to the very thing we are in search of, they may at least discover to others what may be of service.

"According to our principles, the distance between each plant ought to be equal throughout the whole length of the rows, that all of them may have an equal quantity of earth to draw their nourishment from.

"Several experiments have shewn, that six inches is not too great a distance for the plants to be at from one another. In this case it would be necessary to sow one grain of wheat at every six inches distance. According to this disposition, a field well prepared ought to produce the greatest crop. The plants will commonly branch out so as to have twenty, thirty, or forty stalks: I have had some with upwards of eighty. It is pity that this exact distribution of the seed cannot subsist long. An accident I lately met with soon convinced me that it was necessary to increase the quantity of seed, and that very considerably.

"This does not, however, yet hinder me from thinking, that if any easy method could be found to have a plant of wheat exactly at every six inches distance in the rows, it would be the best way of sowing lands. I have often considered how this could be reduced to practice, as well to satisfy my curiosity, as to enable me to proceed with more certainty in my operations. When a theory is known to be good, we are strongly encouraged to draw all possible advantages from it for the practical part; we proceed with confidence and pleasure.

"Experience having convinced me that it never would be possible to have a plant at every six inches in each row,

by sowing only a single grain of wheat at those distances, it naturally followed, that the way to have the ground better covered with plants was, to sow more grains. The next question was, how many grains should or ought to be sown in each place? Should it be two, three, or more? Experience only could answer this question. I therefore tried the following experiment. I sowed a different number of grains in clusters, six inches distant from each other, putting one grain in the first, two in the second, and so on to the sixth, which had six grains: then I began again, and went on as before, till the whole length of the row was sowed in this manner. The produce of each cluster was to shew me whether it would be best to double, triple, or quadruple the seed, which it was plain had been sown too thin, when a single grain was dropped at every six inches.

"The winter of 1753 was already far advanced when these thoughts first occurred to me. It was then too late to try this experiment with wheat; but that I might not lose a year, I did it in the spring with barley; not doubting but that corn, which is usually sown in March, might furnish me with some future hints for the culture of that which remains longer in the ground.

"Accordingly on the ninth of April 1754, I ordered another bed to be sowed with barley in my presence, and in the manner I have just related. I counted all the grains of each cluster myself. They were sown in three rows. I varied the experiment in the rows next the south, by sowing no clusters there of less than three, four, five, or six grains; which I continued the whole length of the row. At harvest, all the clusters in which several grains had been sowed, were so thick, that they touched one another.

"What is of most consequence to our culture is, to know the produce of each cluster. But it will be necessary previously to observe, that the clusters were sown in rows extending forty feet in length, and that the beds were five feet wide.

"Results:

The South row,
sowed with 6, 5, 4, and 3 grains,
produced 661, 624, 447, and 493 stalks.
In all 2225 stalks.

The Middle row,
sowed with 1, 2, 3, 4, 5, and 6 grains;
produce 48, 72, 147, 204, 219, and 417 stalks.
In all 1177 stalks.

The North row,
sowed with 6, 5, 4, 3, 2, and 1 grain,
produced 502, 372, 345, 276, 200, and 92 stalks.
In all 1787 stalks.

"Consequently the whole number of stalks in the three rows was 5189. They yielded seventeen pounds of grain, besides a very considerable quantity shed in cutting.

"On the footing of this crop, an arpent of thirty-seven square toises (equal to about one acre and three quarters of a rod English) would contain at least forty-four beds five feet wide, which was the breadth of the beds of which this experiment was made. The beds would be 222 feet long: the produce of one of them would be ninety-three pounds, eight ounces; and that of the forty-four, 4138 pounds, eight ounces; a very considerable crop, and which might be carried still further by other experiments of the same kind.

"The following observations deserve the reader's utmost attention. First, by this experiment, I have very nearly effected what I aimed at, viz. to have two or more plants grow so close together, as to seem but one; and that at six inches distance from each other. If the three rows had been joined together length-ways, they would have been 120 feet long, and ought to have contained 240 plants only: but the distances, which were marked by guess, not being exactly six inches each, ninety-six clusters were sown in each row, which made sixteen cluster over and above. By this means several of them were nearer than six inches to one another.

"Two hundred and eighty-eight clusters were sown, all of which produced plants, except twenty-five, which either did not sprout, or the plants perished. This deficiency is not very considerable; but we must observe, 1. That almost all the places where this happened had been sown with

with only one or two grains of corn. 2. That it was in the middle row that the greatest number of plants was wanting. 3. That the fourth row, in which the smallest quantity sown for any one tuft, was three grains, furnished and retained its full number of plants: and lastly, that almost all those which were next to the vacant spaces, were stronger than the rest, and thereby made amends for the loss of the others.

"Secondly, the whole number of the stalks amounted to 5189, which is after the rate of forty-three stalks and a quarter to a foot: but it is much more considerable in the fourth row, which having produced in all 2225 stalks, the proportion is fifty-five and a half to a foot. The cause of this difference is easily seen. The exposition of that row to the south being more favourable than that of the others, may have contributed thereto; but it was very plain that it was chiefly owing to none of the clusters in that row being sown with so few as one or two grains.

"Thirdly, we see that the increase of the stalks was, in general, in proportion to that of the seed; only the clusters that were sown in three grains in the fourth row, produced forty-six stalks more than those which were sown with four grains; but still the general result of the three rows was exactly in the same progression, as appears by the following recapitulation:

RECAPITULATION.

Stalks produced by	1 grain	-	-	-	140
	2 gr.	-	-	-	272
	3 gr.	-	-	-	916
	4 gr.	-	-	-	996
	5 gr.	-	-	-	1215
	6 gr.	-	-	-	1650

Total 5189

"Fourthly, the ears were nearly equal, at least in two thirds of the length of the rows: the other third surpassed the rest very considerably.

"Fifthly, the difference between the produce of the clusters sowed with one, and with six grains, is extremely great. The former produced but 140 stalks, the other multiplied to 1650. It is true the number of the clusters of six grains is greatest, which is some small diminution of this difference.

"Sixthly, I observed several stalks from which others had shot out, all as strong, and as long, as those from which they derived their origin. They proceeded from the first joint above the surface of the earth, generally at the height of three, four, or five inches, and were two, three, and sometimes four in number. I never perceived this kind of multiplication before; but had till then always observed it to be at the neck, or point of separation between the roots which descend, and the stalks which ascend, that the stalks branched out.

"Seventhly, I suspected, in the summer, what was the cause of the great vigour of the plants of this experiment; but I saw it much plainer after harvest: for, upon pulling up some of the tufts of stubble, I found their roots innumerable. This fact is strictly true. I could not count them upon any one plant that had more than fifteen or twenty stalks. These roots were in such bundles, and so confusedly interwoven one with another, that after counting several hundreds of them, I was forced to give up the task. Their length and thickness was answerable to their number.

"I must now remind the reader of what I said before, that the several accidents which I met with in my first experiments, shewed me it was necessary to increase the quantity of the seed. I did so, by small degrees, from year to year. It is equally important for the success of the New Husbandry, not to run into another extreme, by loading the earth with more plants than it can nourish: the crop would be considerably diminished thereby.

"It appears from this experiment, that the plants of the clusters that were sowed with six grains did not hurt one another: on the contrary, their being sown in that manner proved an advantage, since they produced much more than the others; whence it follows, that we may, without danger, extend the quantity of seed beyond the limits of the New Husbandry. Its principles are not the less true; but they leave the farmer at liberty to use his own prudence in the application of them, according to the nature of the soil.

"Those principles, which suppose that every plant is to subsist till harvest, reduce the seed to a very small quantity: but numbers of accidents destroy many of them. Our reason ought therefore to tell us, that without deviating too much from the principles we adopt, we may, and should, judiciously stock our land with a sufficient number of plants, in order to guard against unavoidable accidents.

"Still I may be asked, what is the sufficient quantity? I answer, that our experiment shews, that sowing six grains together in a cluster, at the distance of six inches from each other, all the length of the rows, will not be found too thick. By following this rule we may be almost certain that the whole ground will be stocked with a proper number of plants. This ought, however, to be looked upon only as a general proposition, which it will be often proper to deviate from in the circumstances we are going to mention.

"When the sowing season is favourable.

"When the land is well prepared.

"In countries where the winter is seldom severe.

"When the land is but little liable to insects.

"When the land is not in danger of being hurt by too much drought, or too much wet.

"And lastly,

"When the land is good, and very fertile.

"In all these and such like cases, less seed should be sowed; and, in the contrary cases, more. Prudence, and a careful study of the nature of the soil, ought to be our guides. Two or three years experience will be sufficient to shew us the practice that will be best to follow.

"It will be right to repeat our last-mentioned experiment, and even to vary it. In all probability it will afford us still greater lights. It will be right, for example, to sow the clusters with a great number of grains, beginning with six, the produce of which is known, and going on to seven, eight, or even more, always in clusters, till we come to a number of which the crop ceases to yield an equal profit. By this means the two extremes may be known, either of too much, or too little seed; and the just proportion will then be easily determined.

"Some farther alterations may likewise be made in this experiment. For example, I placed the grains in the earth so that they touched one another; they may be placed at some little distance, and ranged in a kind of circle of about three inches diameter. It is reasonable to think, that the plants may then make a greater progress, as they will not at all have one common center: some of them will be nearer the ploughed alley; their roots will reach it more easily than before, and will multiply there, which may render the plants more vigorous." *Dubamel's Culture des Terres, tom IV.*

CLUSTER-GRAPE, the small black grape, generally called the currant.

COAL, the common fossile fuel.

COAL-ASHES. See the article *Coal-Ashes*.

COAL-BALLS, a composition of culm, or the dust and refuse of pit-coal, mixed up with mud, clay, &c. burnt as fuel.

About Bristol, Brislington, and other places in the west of England, they commonly make coal-balls of their culm, or small refuse-coal, which would not otherwise be saleable.

The method of making these balls is, to take a certain quantity of the culm, and an equal quantity of sleet, or mud left by the tide on the sea-shore: these ingredients are first mixed grossly with shovels, and then blended more perfectly with the hand: after which they are moulded into balls about six inches diameter.

These balls may either be burnt immediately as soon as they are made, or laid up and kept as long as the owner pleases, without suffering the least damage.

The inhabitants of Croken-pill, near Ring-Road, about seven miles below Bristol, are supposed to make them in the greatest perfection. They seldom use any other fuel, and find it answers extremely well, being much cheaper than coal, making as good a fire, and lasting longer. They make it a rule to work as much culm into the sleet with their hands, when they mould the balls, as they possibly can, without making them crumbly.

These balls have not been used above thirty or forty years in the above parts; but are now greatly preferred, though they can have coals laid in at three-pence half-penny the bushel.

In Wales, where these coal-balls are also made, they use clay instead of the sleet, allowing two parts of culm to

One of clay, adding to the heap a sufficient quantity of water, which they temper with it, in the same manner as if they were making mortar with lime and sand. And after the culm and clay have been sufficiently mixed and tempered together, they form the whole into balls, in the manner above related.

The balls made with clay are not so pleasant a fuel as those made about Bristol with fleech, because the clay is apt to emit a stinking smoke, especially if the balls are burnt before they are dry: but notwithstanding this inconvenience, which the lower sort of people little regard, they afford the poor a good and cheap fuel.

It is surprising that some work of this kind is not undertaken in the neighbourhood of London, as it would greatly tend to lessen the enormous expence to which the poor of the metropolis are every winter subject, for fuel; and could not fail of rewarding the undertaker for his trouble. Culm might be imported into the Thames very cheap, and nothing could be more suitable than the river mud to mix with it, in order to form the balls; it would, probably, do better than the fleech, being of a richer, and more combustible nature.

COAL-SOOT, the soot collected in chimnies, &c. where coals are burnt. A correspondent of the editors of the *Museum Rusticum* has obliged the world with some useful observations on coal-soot as a manure. He observes, that many farmers in some countries are at a loss to find a proper dressing for their meadows; and to such he recommends the use of coal-soot as highly profitable and advantageous; its effects will be very visible for upwards of three years, during which time no other manure need be laid on the land.

"Coal-soot, says he, is of a very warm refreshing nature: it cherishes, and gives nourishment to the grass; it kills the noxious insects that infest the crop, and protects it from the effects of frosts, snows, and chilling rains; and, what is still of greater consequence, it will kill the moss that often abounds in four meadows.

"I must not however fail noticing, that soot will not have these good effects if the meadow-land should be so damp as to require draining: in this case cuts must be made across it, in proper directions, previous to the laying on the coal-soot, which would otherwise be of little service.

"All rank weeds should be carefully grubbed up from among the grass, and that before they have perfected their seeds; without which precaution, in point of time, the work would be to do over again.

"The general quantity I lay on an acre of meadow-land is twenty-five loose bushels: more I find to be rather prejudicial, and less does not answer all the purposes we are to expect from this excellent manure.

"The best time for applying this dressing, I take to be the beginning of the spring: about February is the time I generally lay it on; the gentle rains which then for the most part ensue, wash it into the land, and the following crop is greatly benefited by it. This is very soon visible from the fine deep verdure which the grass assumes.

"Some of my meadow-land is particularly subject to be damaged by frosts, snows, &c. on this I generally lay the proper quantity of soot in the beginning of November; and sometimes, if the winter is likely to be severe, I venture to allow thirty bushels to an acre, which in other cases I never do.

"Having myself found great benefit by using this coal-soot as a manure for meadows, I am willing my brother farmers should know it; that they may have it in their power to adopt the practice, if they approve of it.

"It will be well worth their while, provided they can have it at a reasonable rate, which they may, if they do not live more than twenty miles from London, by land-carriage, and wherever there is a communication by water, though at almost ever so great a distance.

"Other great towns also, where sea or pit-coal is burnt, may supply the farmers with it; but this misfortune is, that where it is in the greatest plenty, they least know the use of it.

"Great care however should be taken to get it genuine and good, the merchant chimney-sweepers, frequently to increase the bulk, mixing the fine sifted coal-ashes with it: this is a great fraud, but may easily enough, with proper care and circumspection, be discovered; for the ashes make the soot gritty, and increase its weight in a very sensible degree.

"Before I conclude, I must give my brother farmers a caution; which is, that they never lay the soot on their land in windy weather, as not only great part of it will be lost and wasted, but the remainder will be so unequally disposed, as to do rather more harm than good. *Museum Rusticum*, vol. I. p. 218.

Coal-soot is also an excellent dressing for green wheat in February; it should be sown by hand, in quantity sufficient to blacken the ground. This is frequently practised in Leicestershire, and many other countries. It is of a warm nature, and therefore does most good on cold, moist, clayey soils.

COB, a wicker basket to carry on the arm. Hence a feed-cob, or feed-lip, is a basket for sowing.

COCCIFEROUS Plants, such as bear-berries.

COCK, the male of the hen; also the male of any small birds.

COCKEREL, a young cock.

COCKLE, the same with darnel-grass. See DARNEL-GRASS.

CODLING, a well known species of apple. See the article APPLE.

COFFIN, that part of the horn or hoof of a horse which appears when he has his foot set on the ground.

COFFIN-BONE, that bone which lies within a horse's hoof as in a coffin.

This bone is round upwards, where it receives the little pastern, but grows broader and thinner towards its bottom; it is of a porous open texture, like a piece of loaf-sugar, and is easily pierced, and often wounded when horses happen to take up nails or other sharp bodies in the streets or roads: accidents to which they are often liable, and are more easily cured than they would have been had the bone been hard and solid.

COFFIN-JOINT, that where the lesser pastern joins the foot.

When the coffin-joint is strained, a horse often continues a long time lame, without the owner's discovering where the lameness lies; because a horse does not, at first, favour it much on the bending of the foot, only in planting his foot upon the ground: but in time, there will grow such a stiffness in that joint, that he will only touch the ground with his toe, and it will be impossible to play the joint with one's hand. The only method of removing this stiffness is blistering and firing, which generally succeeds, unless the stiffness and contraction has been of long standing. *Gibson's Farriery*, vol. II. p. 372.

COKE, pit-coal, or sea coal, charred. It is made by burning pit-coal in ovens constructed for that purpose, and extinguishing the fire in the same manner as is done for charcoal.

COLD, the name of a disease to which animals of almost every kind, particularly horses, are very subject.

Colds are caused by an obstruction of perspiration: that is, the pores, or outlets of the skin, are so far shut up, that the steams of perspirable matter are checked so, that they cannot pass off in their usual manner. The consequence of this is, they recoil on the blood, vitiate its equality, over-fill the vessels, and affect the head, the glands or kernels of the neck and throat, the lungs, and other principal parts.

It would be endless to enumerate the various causes of colds; the most usual are, riding horses till they are hot, and suffering them to stand in that condition, where the air is cold and piercing; removing a horse from a hot stable to a cold one, and too suddenly changing his cloathing; hence it is that horses catch severe colds after they come out of dealers hands; and by not being carefully rubbed down, when they come in hot, off journeys.

The signs of a horse's catching cold, are a cough, heaviness, and dulness, which affect him more or less in proportion to the severity of it; the eyes are sometimes moist and watery, and the kernels about the ears, and under the jaws swell, the nose gleans, and he rattles in his breathing; and when the cold is violent, the horse will be feverish, his flanks work, and he will both loath his hot-meat and refuse his water. When these last symptoms are attended with a slimy mouth, ears and feet cold, and a great inward soreness, there is danger of a bad fever.

But when the horse coughs strong, snorts after it, is but little off his stomach, pricks up his ears, and moves briskly

briskly in his stall, dungs and stales freely, his skin feels kindly, and his coat does not stare, he is in no danger, and there will be no occasion for medicines of any kind; but, you should bleed him about two quarts, keep him warm, and give him feeds of scalded bran, with as much warm water as he will drink, in order to dilute his blood.

If the disorder should increase, the horse feel hot, and refuse his meat, bleed him, if a strong one, two quarts more; and if you are not satisfied, without giving medicines, avoid, as you would poison, a farrier's drench; which is generally composed of some hot nauseous powders, given in a quantity of ale: which too often increases the fever, by over-heating the blood, and palls the horse's stomach by its loathsomeness. And instead of it, infuse two ounces of anniseeds, with a dram of saffron, in a pint and a half of boiling-water; pour off the clear, and dissolve in it four ounces of honey; to which may be added four spoonfuls of salad oil: this drink may be given every night; or one of the following balls, provided there is no fever; in which case, it always will be more eligible to give two or three ounces of nitre, or sal prunella, every day in his feeds, or water, till it is removed; but should the horse be inclined to costiveness, remember that his body should be kept open by emollient clysters, or cream of tartar dissolved in his water, to the quantity of three or four ounces a day.

Take of the fresh powders of anniseed, elicampne, carraway, liquorice, turmeric, and flour of brimstone, each three ounces; juice of liquorice four ounces, dissolved in a sufficient quantity of mountain; saffron powdered half an ounce, salad-oil and honey each half a pound, oil of anniseed one ounce; mixed together with wheat-flour enough to make them into a paste.

Or, Take the following from Dr. Brachen:

Take anniseed, carraway-seed, and greater cardamoms, finely powdered, of each one ounce, flour of brimstone two ounces, turmeric in fine powder one ounce and a half, saffron two drams, Spanish juice dissolved in water, two ounces, oil of anniseed half an ounce, liquorice-powder one ounce and a half, wheat-flour, a sufficient quantity, to make into a stiff paste, by beating all the ingredients well in a mortar.

These balls consist of warm opening ingredients; and, given in small quantities, about the size of a pullet's egg, will encourage a free perspiration; but, in case of a fever, should be cautiously continued. They are much more efficacious, and in all cases superior to the farrier's drenches, if dissolved in a pint of warm ale.

This simple method, with good nursing and hot mashes, warm-water and cloathing, especially about the head and throat, which promotes the running at the nostrils, will answer in most sudden colds; and when the horse feeds heartily, and snorts after coughing, moderate exercise every day will hasten his recovery.

The scalded bran should be put hot into the manger, for the steams conduce not a little to promote a running at the nose, which is often very plentiful, and greatly forwards the cure. His manger should be kept clean, by filling it with straw; his hay well shook and sprinkled with water, and given in small quantities: for his breathing, at this time, taints the hay, and then he will not touch it.

To a horse loaded with flesh, a rowel may sometimes be necessary, as may also a gentle purge or two, to some, when the distemper is gone off. *Bartlet's Farriery*, p. 26.

COLD-CHARGE, the name of a medicine much used by farriers for curing strains, &c. It consists of vinegar, bole, and the whites of eggs, mixed together to the consistence of a poultice, and spread over the part hurt.

COLE, or **RARE**, the name of a plant greatly cultivated, both on account of its seed, being that from whence the rape-oil is drawn, and also for feeding cattle. The botanists call it *napus sylvestris*, or wild mallow.

The marquis de Turbilli, who has done more service to agriculture than any other foreign writer, has lately published a Memoire on the culture of cole-seed, as practised by the Flemish farmers, to whom we are indebted for many valuable improvements in husbandry.

In the piece above-mentioned, the marquis observes,

that all sorts of cole-seed are cultivated in the same manner; and that all grow more or less towards their natural perfection, yield more or less seed, and this seed is of a better or worse quality, according to the nature of the soil on which the cole-seed is sown, the good or bad husbandry bestowed on it, the favourableness of the season, and the manner in which it escapes other accidents to which it is subject.

Cole-seed, he says, thrives best in deep kindly soils; but with plenty of manure, and deep ploughing, it will grow any where. He adds, that he has seen it yield good crops on a dry chalky soil, on which street dirt had been previously laid.

We must observe, that this is a very useful piece of knowledge to propagate, as we never yet heard of any farmer in England, who ventured to sow it on such a soil. This should be attended to by the Bedfordshire farmers about Dunstable, &c.

Our noble husbandman next remarks, that in Flanders, cole-seed is sown and transplanted like cabbages: they give two ploughings to the land before winter; and it is not of much consequence what crop the land was last under.

In the month of May another deep ploughing is given; the land is harrowed two or three times, and then rolled, in order to make it fine. Towards the eighteenth or twenty-fourth of July, it is again ploughed, harrowed, and rolled till it is reduced to as fine a tilth as possible: the seed is then sown, being scattered by the three fingers: the land is lightly harrowed, and afterwards rolled.

The marquis says, that twenty-four pounds of seed will sow three acres, and the plants of these three acres will fill twelve others. Cole-seed is transplanted after any crop whatever.

The land intended to receive the cole-seed plants should be twice ploughed as soon as the crop is carried off. About ten or fifteen days afterwards it is to be once or twice harrowed, and towards the end of September it should have a very deep ploughing. In this last ploughing there should be an open furrow or trench every five bouts. If the field does not lie level, it should be ploughed obliquely, so that there may be an easy fall for the water.

The best and most promising plants being taken up, and tied in bunches, are carried to the field where they are to be transplanted, by the time the last ploughing is completed, and the workmen are ready for them.

There will always remain a number of plants in the land where they were sown: these are generally fed off with cattle; for the farmers never let them stand to ripen their seeds, unless they intend to manure the land for the succeeding crop.

The season in Flanders for transplanting cole seed is the beginning of October. The plants are placed in rows across the furrows. The rows are one foot asunder, and the plants in the rows about six inches distance one from the other. The manner in which this work is done is as follows. A certain number of men advance in a parallel line, each having a dibble, or spade-handle, with two large iron points to it, six inches asunder: they drive this instrument into the ground; the women and children follow, who put a plant into every hole, and settle it at the same time; which is easy enough to do, and it saves some expence.

Then all the cole-seed is planted; if the land to which it was removed was not dunged before it was ploughed, it must be sown with pigeons dung reduced to powder: this, of all other manures whatever, has the most immediate and proper effect on the vegetation of this plant; sixty bushels are enough for two acres.

When this is done, the loose earth in the trenches, or open furrows, is to be thrown with a shovel amongst the plants in the rows. Early in the spring, a spit of earth out of the trenches is, in like manner, to be cast amongst the plants of cole-seed in the rows. This slight tillage gives vigour to the crop, chokes the weeds, and keeps the soil loose.

The rows of cole-seed form a number of beds, and when it thrives well, the trenches are entirely covered, and the whole resembles a thick copse.

Here the marquis observes that cole-seed thrives perfectly well in new-inclosed lands.

The seed is fit to gather about the beginning of July.

T t

When

When it turns yellow, it is reaped like corn, and laid in pretty large gavels on the beds, where it remains three or four days; it is then carried in cloths, in order to prevent any of the seed from being lost, for it is very ready to drop.

In one, or several parts of the field, in proportion to its extent, and to the quantity of cole-seed there is, the crop is formed into several stacks. The Flemish farmers never thatch these stacks; they know so well how to make them, that the rain does them no damage. The cole-seed heats in the mow, by that means yielding more oil than it would have done, if it had not been stacked.

In the month of September they make a kind of floor in a field, whereon they thresh and dress their cole-seed. If a farmer should incline to thresh his cole-seed without stacking, it will be necessary for him to leave the gavels longer exposed to the air on the beds. Cole-seed may be cut at any time of the day, provided it does not shed; if it does, it should only be cut mornings and evenings. As a whole field does not all ripen at the same time, it should be cut in different portions; being laid in gavels, or heaps, the changes of weather will not affect it. It may safely be stacked three or four hours after rain, provided it has previously been some time in gavels, and is judged sufficiently dry.

In order to clean the seed, parchment sieves are used, if there is any wind stirring; but if it be calm, they use wind-fans.

Cole-seed should not be sown on the same land above once in five or six years.

In the neighbourhood of Clermont, in Beauvoisis, the marquis tells us, that they let the cole-seed ripen in the field where it was first sown; but if they considered that cole-seed is not fond of moisture, that it sends forth large roots into the earth, and grows to a great height, with numerous wide extended branches, they would be sensible that the land, being covered with too many plants, must be impoverished; and that plants, which stand so close together, cannot attain their full size: thus, in this way, the land is impoverished, the weeds are left to perfect and shed their seeds in it, and not only the crop of cole-seed is very indifferent, but also the crops which succeed it. In order to restore such land to a good condition, it should be well manured and fallowed.

Cole-seed extracts such a quantity of salts from the earth, that the Flemish farmers transplant it, as well to divide betwixt two pieces of land the losses in point of quality it occasions to the soil, as to procure better crops. For both these reasons, they also sometimes transplant their cole-seed on land newly broke up.

In the country of Amiens they transplant their cole-seed after the plough in close furrows: this method is better than that above-mentioned; but it is greatly inferior to the Flemish method; for the rows are disordered, and the plants crushed by the horses feet; and having, besides, no fresh earth laid on them, they cannot grow to such fine plants; and, on the other hand, the earth, which is not kept stirring, cannot receive any considerable benefit from the influences of the air.

The marquis observes, that there is, however, a case in which this method must be resorted to; which is, when the plants are grown so tall, and have such long roots, that proper holes cannot well be made for them with a dibble, they should be laid in the furrows after the plough, and open furrows, or trenches, should be left at the distances already mentioned; but the earth from these trenches is with greater difficulty thrown on the beds, because the cole-seed, in this method, is planted lengthwise, whereas in the other method of transplanting, the plants cross the beds.

In this essay the marquis de Turbilli relates a very curious fact, which we shall insert in his own words.

"In the year 1755, I saw in the neighbourhood of Guise, in France, some cole-seed transplanted into a field, containing about eighteen acres, which had always borne fine corn, but had no great depth of soil.

"At the depth of seven or eight inches from the surface lay a bed of red clay, which the farmers are so much afraid of mixing with their good earth. This land was first well dunged, and when the cole-seed was transplanted, the red earth out of the trenches was thrown on the beds.

"All the inhabitants of the country flocked to see this work executed, which was under the direction of a Flemish

farmer. They pretended that he spoiled the land, and that no corn would grow on it afterwards.

"However, during the course of the winter, and red clay became mellow; the rains which washed the dung, ran into the trenches, carrying with it a sediment, and a portion of salts improving the earth that was in the ensuing spring to be thrown on the beds amongst the rows of cole-seed, which came on amazingly.

"At the harvesting of the next crop, the inhabitants did not fail of coming to see what sort of corn succeeded the cole-seed; and being perfectly well convinced that it was much finer than the land was accustomed to bear, they laid aside their prejudices, and adopted the planting of cole-seed. In the year 1761, there was in that single quarter above one hundred acres of transplanting cole-seed."

Must we not, on such good authority, allow that the notion of the under-turf earth being poisonous is ideal? If indiscreetly laid over the surface of the land when it either is, or is to be sown, under certain crops, it may be prejudicial, and so may the best practices in husbandry, if injudiciously followed.

A correspondent of the editors of the *Museum Rusticum* has given us the following method of cultivating cole-seed in Essex. He begins with observing, that the great consumption of rape-oil in that country in manufactures, together with the natural richness of their land, induces them often to sow the cole-seed or rape-seed, which thrives there extremely well.

"In moist soils, continues he, we sow it on four-bout lands, the large furrows between the ridges serving to drain off the water.

"We do not trust to the richness of our land alone, for we almost always lay on a considerable quantity of manure; being of opinion that land cannot be in too good heart for this plant, which requires a great deal of nourishment, having a very luxuriant growth, and draining the land much: for this reason, it is in vain to attempt sowing it on poor, hungry, dry soils, on which it will never thrive, nor turn to profit.

"Land cannot be too mellow, nor too much pulverized, for the cole-seed plant; for it not only requires a rich soil, but also the land must be in excellent tilth: we allow land, on which it is to be sown, sometimes three or four ploughings, according to the nature of the soil: if stiff, it requires more tillage; if a loose, rich, crumbly loam, less ploughing will do.

"In July we harrow the field over, and afterwards sow on it half a peck of seed to the acre broad-cast. As soon as the plant gets out of its seed-leaf, I hoe it as I do my turneps, thinking this a better way than to let it grow rambling without after-culture, as some of my neighbours do.

"This crop is, without care, very apt to be destroyed by slugs, whilst the leaf is young and tender; but to prevent this, I always strew over the young plants a mixture of slaked lime, and wood-ashes; about ten bushels of slaked lime, and fifteen of the ashes, will be quite sufficient for an acre: this is the quantity I use.

"I find great benefit from this practice, as it not only burns up the slug, and destroys many pernicious insects, but also greatly helps to forward the crop, inasmuch that it gets to a strong head before winter, and yields me a plenty of fodder for my cows, sheep, &c.

"A part of my ground will sometimes unaccountably fail: that is, the seeds will not come up; but as the cole-seed plant bears transplanting extremely well, I make my men remove some of the plants, where they stand too thick, to supply the deficiencies: these are sure to take, especially if rain ensues: if it does not, I cause them to be watered, which is soon done, as they seldom fail in great quantities.

"The cole-seed plant is so hardy, that it bears without injury, the frosts of our severest winters; but the north-easterly winds, if very cold and piercing, will sometimes greatly injure a crop, and there is no guarding against these.

"We sometimes in this county sow cole-seed merely for the sake of the winter feed it affords our cattle; in which case we plough it up early in the spring, and are almost sure of a good crop of sound barley. This is not generally practised, because it requires great care to clear the land of the cole-seed plant, which would otherwise grow up with the barley, and injure it; I, how-

ever

ever, and some others, have often practised it to advantage.

"One thing I must observe, before I conclude, which is, that cattle must be fed with this plant with great care, or it will have fatal effects: it is best to give them with it, at times, sweet dry hay: this corrects the superabundant moisture of the plants, and serves to dry up the uncorrected and raw juices that would otherwise mix with the mass of blood in the cattle: suckling ewes may feed on it heartily, however, with very little danger; and in fact, experience will soon direct the young farmer in the management of his cattle in this respect.

"We reap, for the most part, our crops of cole-seed; and as it is very apt to shed, we prepare frames lined with threshing-cloths, each drawn by one horse, to receive the heads of the plants as fast as they are cut off.

"When this crop is properly managed, nothing pays better." *Museum Rusticum*, vol. I. p. 237.

Another correspondent of the editors of the above work, gives the following method of cultivating cole-seed in the fen countries.

He observes, that they make use of no muck or compost, but have recourse to the method of burn-baking, which we have already described under that article. See BURN-BAKING.

As soon as the land is burnt, and the ashes spread, it is immediately ploughed, and the seed is sown as soon as possible.

"The quantity we sow, continues he, on an acre is about half a peck, or rather less: it would be proper to draw a light hurdle, stuck with thorn spray, over it, by way of prevention against the fowls. We plough the land about ten paces wide, that the furrows may carry the water off, where the land lies on a little descent.

"There is one thing to be observed in the ploughing, if the square of the piece will admit of it: you should plough for burning from east to west, and when you plough for sowing, then plough north and south, for these reasons: first the land will break better for being cross-ploughed: and then the land, when sown, will lie as it were full face to the sun; but this cannot always be done.

"As soon as the cole-seed begins to sprout, it is often all destroyed with what we call a black fly; an insect so small, and being black, the same colour of the land, that it is almost impossible to see it, otherwise than as you walk among the seed, if you look steadily, you will perceive something hop or fly off, like the hopping of a flea: I have often endeavoured to discover what sort of fly this is, but never could find one, though they will find the seed immediately on its first sprouting.

"It has many more enemies as it advances in its growth; the next is what we call the black canker; it is a small black worm, about a quarter of an inch long, or rather more: this takes possession when it is about the size of a small cabbage-plant, but windy and rainy weather are great helps to the destroying that insect.

"There is yet another enemy, but he appears in a different dress: this is the green caterpillar, more than an inch long, but does not appear till about the latter end of September, and very often destroys a great deal of it; but the frosty mornings generally dispatch him.

"I have now gone through the various steps of the culture of cole-seed to this particular period, with a supposition, that we have escaped all those dangers. I will now give you a short sketch how we proceed when we are attacked with those enemies above-mentioned.

"If the small fly eat the first sprout, it is usual to sow the land again: but I would advise the farmer before he sows, to harrow the land with a light harrow with wooden teeth; for if the harrow be heavy, it will tear up the furrows: my design in this is to raise a fresh mould, by which means the seed will strike much sooner than if nothing was done to it.

"As to the black canker, the only method I can advise is, to let two men take a waggon rope, each take one end, and draw it over the plant about twice in a place, by which means the canker will be beaten off the plant on to the ground, which seldom rises again.

"As to the green caterpillar, the same expedient, I believe, would be of service to that; but as I have said before, we are chiefly relieved from it by frosty mornings."

The writer then proceeds to give his readers an account

of the uses the cole-seed is put to in the fen countries, when the plant is arrived to its utmost perfection.

"We eat off, says he, with sheep that are about half or three parts fat to make them fit for the butcher; for cole-seed is the most fattening food for sheep that is known in this part of the world, greatly exceeding turneps, as a sheep will thrive more at cole-seed in one month, than it will at turneps in two.

"The usual time of putting them into the feed is about Michaelmas: however that depends upon the farmer's own convenience; but if the sheep are poorer than as above described, they must be put in sooner. We generally manage so as to have the feed eaten off by about Old Candlemas, for this reason, if the land be stout and good, there is a chance for the seed to stand for a crop.

"If the farmer finds the seed good enough to stand for a crop, I would advise him, if the stumps or stalks be left high, as where the cole-seed is strong and good is mostly three or four inches off the ground; otherwise he will find his crop will receive great damage by the stumps being left very shagged and torn, which lets in the wet, and rots a-bundance of them; and even those that do grow have not the vigour as those have that are mowed; for the former is as it were, spread to the snow and rain, while the latter is wholly secured from them both, and will support the sprouts, that shoot out at the sides with strength and vigour.

"Cole-seed is a plant that will shed or shale its seed very greatly, if it is not reaped in proper time; from which great losses have been known, where the farmer has thoughtlessly let it stand too long before he begins to reap.

"If the season has been kind, that the crop comes on all together, though we often see the contrary, the farmer is, in either of these cases as soon as he perceives any part of it turn brownish, to begin to cut, notwithstanding the generality of the seed will be green; but if you let the whole stand till the last becomes brown, like the first, the first part will be entirely lost.

"But it will perhaps be said, should not the latter part be as ripe as the first? My reply is, as cole-seed is a small seed, and the stalks on which it grows are very large, the stalk will feed that part that is green, after it is reaped, so as that of the latter will be nearly equal to the first: by which means both are saved.

"There is a particular method of laying it on the ground, when reaped, different from all other corps; for instance, suppose the people reaping a field from north to south, every two men should lay in their reaps, with the heads of the seed to each other, but not to touch, the heads and the ends of the stalk lying east and west. We shall now proceed to the threshing.

"The distance of time between reaping and threshing depends so entirely upon the weather, that it is impossible to give particular directions in that matter, otherwise than than when the seed has lain till the stalk or straw is dead, and turned white, and the seed some of it being rubbed out of the coss or pod, appears black and plump, and does readily come out, then is the time to begin to thresh.

"Though the bottom of the reaps will be a little greenish, they must be not turned to weather the under side; if you do, it will brush out a great deal of the top side: and if the weather should prove wet in the time it is threshing, even in that case it must be turned, but raised up gently and laid lightly on the stubs, in that situation they will dry apace.

"It is always threshed in the field, upon a cloth, about twenty yards long, and eighteen yards wide. To describe each person's employment, I think, it is not to be done, so that a person that never saw it can have an idea of it; but as it is, I think, if every person concerned in a cole-seed sale, for that is the name we give the cloth and people when at work, be clever in their places, it is a curious piece of mechanism, if I may be allowed this expression, where men and women are made use of instead of wheels and pulleys.

"The number of people employed at a cole-seed sale are, generally, about twenty: seven gatherers; these are women, great boys, and girls: I have said seven; but where the crop is thin it requires more, sometimes eight or ten, or more: but where the crop is thick, a less number may do; these people gather the reaps up with a sickle, for, as their arms cannot reach round the reaps, they would squeeze it together and brush a deal of seed out, if they had no sickle, they

they put it into a sheet called a bearing sheet, of which there are two belonging to every fale: it is about ten feet long, and about seven feet wide, and has loops on each side, through which a light pole is put, and is carried, when filled, by two men to the cloth: these are called the bearers.

"When the seed is laid on the cloth, there is a man called the layer-on: he with a sickle lays it on a row, across the cloth, for the threshers, which are four, two on each side of the row of seed. While the threshers are threshing the first row or floor, the layer-on lays on another row at a proper distance from the other: when they have threshed the second once over, they turn to the first, and thresh it all a second time: they have then done their parts: there are two men called shakers off, that immediately follow the threshers: the first of them throws the cole-seed straw up; the other strikes it as it rises, which helps to knock out what seed may be left: these two men with wooden forks for that purpose, convey the straw off the cloth, over the bolster, to a person that takes it away: he is called the sack-straw.

"After the shakers off, come two persons, one of them a woman: they take off the cosses or pods, and short broken straws, with rakes made for that purpose: these are called the before and behind cavers. The behind caver must be a person of strength and activity, in order to do his work as it ought to be done; for upon him the saving and throwing away of a good deal of the seed depends; so that he should be a nimble brisk fellow, and careful too, or he is by no means fit for that place.

"If there be a good crop, and the plants yield well, the weather bright, and the seed thresh easy, thirty combs, or one hundred and twenty bushels, may be threshed in the day; but sometimes no more than ten or twelve combs.

"Early the next morning the four threshers throw the seed upon the cloth, when the farmer comes with sacks and a waggon, and takes it away, so that the cloth is cleared and ready against the people come to work." *Museum Rusticum*, vol. I. p. 418. and vol. II. p. 79.

If this plant be sown for the food of cattle, they will be large enough for feeding by the middle of November, when if there be a scarcity of other fodder, this may be eat; but if there be not an immediate want of food, it had better be kept as a reserve for hard weather, or spring feed, when there may be a scarcity of other green food. If the heads of these plants are cut off, they will shoot again early in the spring, and produce a good second crop in April, which may be either used for cattle or suffered to run to seed. It is so hardy as not to be destroyed by frost, and therefore of great use in hard, severe winters, for feeding of ewes: for when the ground is so hard frozen that turnips cannot be taken up, these plants may be eat for a constant supply. Mr. Miller says he has found, in several places where he has sowed this seed, that one acre of land planted with cole will produce nearly as much food as two acres of turnips; that this will afford late food after the turnips are run to seed: and that if the plants are permitted to stand for seed, one acre will produce as much as, at a moderate computation, will sell for five pounds, clear of charges.

Partridges, pheasants, turkeys, and most other fowls, are so fond of these plants, that if there be any of them in the neighbourhood of the field where they are cultivated, they will flock thither, and lie constantly among them.

The cakes of cole-seed, which remain after the oil is extracted, are exceeding good for cattle, and will very soon fatten them. They are indeed apt to render the fat of such beasts yellow and rank; but this may be easily removed by feeding them with dry fodder a fortnight or three weeks before they are killed.

"Cole-seed, says Mr. Young, wherever I have remarked the cultivation, has been sown for a crop of seed, as well as food of cattle, but often fed off with sheep, and afterwards reaped for the seed. It is usually sown in the manner of turnips; but I never knew any hoed, even by those farmers that are nicest with the latter crop. It was this circumstance that first induced me to cultivate cole-seed, to discover if I could gain better crops than common, (for sheep) by means of a better than common culture.

The soil of the first experiment, made on half an acre, is a loose woodcock brick earth, and under that a white clay; the field hangs a little to the north. This was ploughed six times, and had four harrowings, sowed broad, and twice hand-hoed. The season was very unfavourable being so very dry, that almost all the turnips in the country were thereby destroyed. Half this experiment ground was hand-hoed in the manner as for turneps, the other half had nothing

done to it. The whole was fed off by sheep. The result was, a loss on the part hand-hoed, of 11. 7s. 7d. per acre. and on the part not hoed, of 18s. 3d. per acre.

"This proves sufficiently the great benefit of hoeing, besides cleansing the land, which is yet more. But I should remark, that the hoeing, if it was a general practice, would be done much cheaper. Labourers always impose when their work is uncommon.

Experiment 2d. made upon a field of four acres, hanging to the north; the soil a strong clay. This land had six ploughings, two harrowings, and two water-furrowings; was sown broad cast, July 1st, and the seed harrowed-in. The excessive drought prevented the crop from rising as it ought to have done, but yet the plants were more numerous than in some turnip fields adjoining. I was induced therefore, as the land had been well prepared, to let it stand. January 24th, I turned into it fifty sheep and three two year old heifers; it kept them just three weeks. The keeping of the sheep being reckoned at 4d. per week, and of the young cattle at 1s. 3d. per week, the value of the produce was 3l. 1s. 3d. but the expence computed, there was a loss upon this crop 1l. 5s. 7d. $\frac{2}{3}$ per acre.

"The greatness of this loss is certainly much owing to the dryness of the season; but such mischances are never to occasion a neglect of trials that are subject to them: all vegetables are liable to such evils, and if one species withstands the enemy better, upon the average of a long period, than another, it is an advantage that ought by no means to be overlooked: experiments registered only in favourable years, are useless, because unfair.

"The sheep and young cattle both affected this food much; but the latter not so soon as the sheep.

Experiment 3d. Half an acre in two divisions, 1776. The soil and exposure the same as in the last experiment. — First division one rood, five ploughings, three harrowings; sown broad-cast the second week in June. — The plants extremely favourable — July 9th, hand-hoed the first time; and again the 24th. The effect of these hoeings was striking — The other rood sowed at the same time, broad-cast, and not hoed. — September 9th, viewed this experiment; the hoed part is as thick as the other, and much more luxuriant, but very few weeds; the other full of them.

March 17th, hurdled the divisions, and fed them off with 60 sheep: the unhoed half lasted them six days. They were turned into the other, which kept them just eight days. N.B. They were taken out of nights and lodged in a small pasture near the field.

	l.	s.	d.
The profit of the rood hoed, after deducting			
all expences	1	19	5
Ditto of the rood unhoed ditto	1	9	11
— Superiority of the hoed per acre	0	9	6

The sheep are very fond of this crop, which agrees perfectly well with them, and the young lambs thrive very much.

Experiment 4th. Half an acre in four divisions, 1766. This piece in the same field as the last experiment. The soil and exposure the same.

Ploughed the whole six times, and harrowed three times, the last ploughing the 27th of June, and by this ploughing struck it into four parts, and sowed,

No. 1. Harrowed-in the seed for broad-cast, for the common management.

2. Harrowed-in the seed broad-cast, designed for hand-hoeing.

3. Thrown on to 5 feet ridges, and drilled a double row on one foot asunder each.

4. Left flat, and drilled in equally distant rows, two feet asunder.

July 15th, hand-hoed No. 2, 3, 4, and hand-hoed the same again, August 6th, — July 21st, horse-hoed No. 3, by turning a furrow from the plants. The 23d, hand-hoed it again, setting the plants out eighteen inches from each other in the rows. August the 12th, horse-hoed No. 3 again throwing the mould to the plants. The 22d, another horse-hoeing, reversing the last. September 2d, another, throwing the earth back to the plants.

The end of March, I moved No. 1. first, and spread the crop upon a piece of dry grass ground, and then turned 15 hogs, about three parts grown, into the field. They took at once to the cole-seed, and fed very heartily upon it.

it. They were kept to it, and it lasted them three days.

No. 2. lasted them seven days.

No. 3. lasted them two days.

No. 4. lasted them five days.

The hogs thrive very well on this food, and none of it was wasted.

The expences of these products being deducted, it appears that they were all unprofitable, in the proportions following :

	l.	s.	d.
No. 1. The broad cast unhoed, loss per acre	1	12	8
2. The broad cast hoed ditto	1	5	10
3. The horse-hoed ditto	2	11	8
4. The drilled in equidistant rows; ditto	1	14	2

From this view the comparative advantages (or rather disadvantages) are pretty clearly seen.

The ill success of this experiment, is to be attributed to more causes than one. The poverty of the crops in point of quantity; and the vegetable not being of that substantial nature which goes far in feeding of the cattle. And yet I think three-pence a week (the price charged in the estimate) a fair price for hogs, that rise when full grown, to about ten stone (14 lb.)—From viewing the field, I should have thought the hoed broad cast crop would have turned out better; but it never carried near so good an appearance as experiment No. 3. But whatever idea is formed of cole-seed in general from this trial, the comparative part of it is very decisive. Drilling is evidently an improper method to cultivate it; and horse-hoeing excessively unprofitable, the expences being very great, and far worse than no purpose. The beauty and luxuriance of the plants in these rows were great, but the superior quality of the others, much more than balanced this circumstance."

We may remark upon these four experiments, that computing the quantity of the crops from the number of cattle fed upon each, is not so accurate and satisfactory, as by weighing the produce of each; and the reason of the drilled equidistant rows, falling short of the broad cast hoed, would have been more apparent, had the distance of the plants in these rows been mentioned. It would seem that the plants stood too thin in the rows: for it is certain from repeated experiments made upon wheat, and other plants of a lesser growth than cole-seed, that drilling them in two rows, at two feet asunder, constantly improves the crops beyond the broad cast sowing, provided the drilled plants are properly hand-hoed.

The very small produce of the horse-hoed crop, is still more extraordinary, as it is allowed by all experienced cultivators, that horse-hoeing improves plants of every kind more than any method of culture hitherto known: for which reason they are allowed more room than in any other way. There is however a medium to be observed; they may be planted too thin for profit, even for horse-hoeing, which seems to have been the case here. For these horse-hoed plants, were upon five feet ridges, two rows upon each ridge, at a foot distance, and the plants were set out to the distance of eighteen inches plant from plant in the rows. By this disposition, every plant occupied a space of a foot and a half square; a space not indeed too great for these plants, where the land is good and well horse-hoed; as appears from an experiment made by Mr. Donellan near Dublin, related in a letter from him to Mr. Wynne Baker, November 8, 1765.

"In a very hard winter, says Mr. Donellan, I observed in my garden, a plant in full verdure above the snow, when turnips were buried a good depth below it. On enquiry I found it was rape (I believe the English call it cole) I tried cows and sheep with it, and found they devoured it with greater eagerness than I had ever seen them eat any other plant. This determined me to try it, and it was answered beyond my expectations, for cows and sheep, especially ewes.

"I have cultivated it ever since, as the best plant for winter and spring pasture, that had at that time come to my knowledge.

I sow the seed about the beginning of July, on good garden ground in drills, and transplant it upon ridges, thrown up from a good fallow at three feet distance the rows, and the plants in the rows about eight inches distance (which I believe is too near) in August, to chuse, when the ground is moist with rain. If it has a favourable season, about Christmas it will be about two feet high; but in March, when the seed branches have shot, near four feet high.

I weighed a middling plant in March 1753, it weighed eight pounds. In 1754, a middling plant weighed ten pounds.

"My butter from the time the cows began to get the rape, was of a rich yellow colour, and had a particular sweetness. And the ewes and lambs were in high order—It must be given to cows with caution, as it will hove them like clover, if given in too great quantities.

"A man will plant eight yards of a ridge in seven minutes. This is all I can recollect in relation to this valuable plant; which for quality, quantity, and lasting, excels all that I have experienced or observed."

Computing from the smallest of the plants that Mr. Donellan weighed, eight pounds, his crop was 73 tons; and 600 weight upon an English acre, which is without doubt a great crop. Mr. Donellan does not mention in what manner he cultivated these plants, but it seems by the disposition of the plants, and his culture of other crops, which he does mention, that these were horse-hoed. His method of planting, adapted them better for the horse-hoeing culture, than in the above experiments where two rows were planted upon five feet ridges: single rows being always more improved by horse-hoeing than double rows; of plants that grow large enough to admit of that manner of planting. We shall next proceed to Mr. Young's last experiment upon this plant; the products of which were weighed.

"Experiment No 5. Upon half an acre in three divisions, 1767. The soil, exposure, &c. the same as in the preceding experiment.

"This piece had seven ploughings, and five harrowings; struck into three parts, and sowed them the 29th of May; viz.

No. 1. With cole-seed broad cast:

No. 2. With turnips broad cast.

No. 3. Was planted with cabbages; the Battersea fort; in rows four feet asunder, and three feet in the rows; the plants of which had been raised in the garden.

"June 15th all three were hand-hoed. The 27th, horse-hoed the cabbages, and hand-hoed the turnips, and cole-seed again. July 18, the second horse-hoeing, the 28th, the third. August 4th, hand-hoed them again. The 6th, the fourth horse-hoeing. All three crops flourished exceedingly: October 5th, cut them all, and weighed the produce:

	Tons	Cwt.	lb.
No. 1. weighed 17 cwt. or per acre	5	0	0
No. 2. weighed 3 tons, 13 cwt. or per acre.	21	18	0
No. 3. weighed 4 tons, 13 cwt.	27	18	0

"They were then given upon a bare grass field, to two large oxen, and two dry cows.

	l.	s.	d.
No. 1. Lasted them two days, which, at 5 shillings a week for the two oxen, and 3s. 6d. for the two cows, comes to 2s. 6d. or per acre:		15	0
No. 2. Lasted them a week, which, at the above prices, comes to 8s. 6d. or per acre	2	11	0
No. 3. Lasted them just a week and a half, which at the above prices, comes to 11. 1s. 3d. or per acre:	6	7	6

From a comparison of these products, with the stated expences of raising them, there appears to be on

No. 1. A loss of 2l. 3s. 9. per acre; and on

No. 2. A loss of 10s. 9d. per acre:

No. 3. A profit of 2l 5s. per acre:

"Cole-seed makes a very indifferent appearance here. The cabbages did not near equal some other crops I have had at various times, but they are much superior to the other vegetables.—All three crops would have improved, had they stood longer (although they were sown very early) but the comparison remains the same. The cabbages, however, would have decayed sooner than either of the others.

"Corollaries to be drawn from these Experiments:

1. Cole-seed is a nourishing and wholesome food for oxen, cows, sheep, and hogs.

2. The quantity of its produce, under the preceding management,

hagement, is inconsiderable, and not upon an average sufficient to answer the expences of culture.

3. The best culture is that of sowing broad-cast and hand-hoeing, as in the turnip husbandry; without hoeing it is much worse, and drilled and horse-hoed naught.

4. Turnips are much superior in quantity and value of produce.

5. Cabbages are greatly superior to it.

Cole-seed, as Mr. Young justly remarks, makes a very indifferent appearance here; and it seems indeed extraordinary, that a plant, which will rise to the weight of eight or ten pounds, should produce no more, by what he reckons the best culture for it, sown broad-cast and hand-hoed, than 5 tons upon an acre: yet as one plant only, weighing 10 pounds, upon a yard square, the produce of an acre amounts to 21 tons, 12 cwt. We have seen that Mr. Donellan's was much greater than this; and if we should suppose that he made a mistake, and that the plants he weighed were larger than the average of his plants, it is not probable that they were twice the weight of the average: yet even upon that supposition, his crop was about 30 tons per acre, and Mr. Young's best crops but 5 tons per acre: a very surprising and unaccountable difference, especially when we consider that the crops were both of them weighed at the same period of their growth, both in the month of March.

This essay on the culture of cole-seed is concluded with the following remarks:

"Cole-seed is one of the most profitable common crops known in England, but not for feeding cattle; nor should I have conceived that any persons could have thought of comparing it with turnips in that light. The profit of the crop is the seed, which amounts to five times the value of any food for cattle that will ever be gained from it.

"I have made enquiries in many parts of the kingdom concerning the culture, and I find that the great object is every where the seed; that in most parts they have no idea of feeding it at all; and that in others, where it is practised, they do it merely upon the same principle that wheat crops are fed off. The farmers are distressed for green food, and they turn their flocks into their wheat and coal-feed, (in many places absolutely against their own judgment, relative to the crop alone) not because such crops were sown for the purpose, but their yielding food when the flock starves.

"Some very sensible farmers, long practised in the culture of cole-seed, with whom I have conversed on the subject, have assured me, that if it is fed when the food is wanted, that is, after turnips are done, the crop of seed is vastly damaged by it, to a much greater amount than the value of sheep fed.

"Some of them have told me, that they have fed off crops earlier, and they think the seed not the worse: but this they mention as a doubt.

"But if the plant be applied to the same use as turnips, and used at the same time, it is agreed throughout the kingdom, that the culture is worthless, not producing near the quantity of food with that crop, nor paying in any respect so well.

"Respecting the culture of cole-seed merely for food, in April and May, that is to succeed turnips, there is one strong reason against it, which is, its not producing a great weight of food per acre. I know, both from my own and other's experience, that the weight of food is trivial, compared to that of turnips and cabbages, &c. I will venture to say not an eighth part, consequently much land must be appropriated to this use, and after the season in question, what quantity of barley or oats will be gained? The sowing will be in May, now it matters nothing to enquire into culture, or any other circumstances; it is clear enough that the spring corn crop is ruined by late sowing. Hence arises the necessity of the spring food yielding a great quantity on a small space of land, that the farmer may experience this evil only in a small degree. Cabbages, which yield as much food on one acre, as ever cole-seed will on six, appear to come infinitely nearer the wished-for mark." *Young's Essay on the Culture of Cole-seed, including Experiments.*

COLE-Cale, or *Keal*, signifies pottage in the northern parts of England and Scotland.

COLEWORT, or *Dorsetshire Kale*, is a species of cabbage, formerly much cultivated in gardens, but at present little known, cabbage plants being substituted in its room. It is however a very useful plant for feeding milch-cattle in the spring, when there is a scarcity of herbage; for it is so hardy that no frost will kill it.

The best method of cultivating this plant in the fields is, to sow the seeds about the beginning of July, choosing a moist season, which will bring up the plants in about ten or fourteen days: the quantity of seed for an acre of land is nine pounds. When the plants have got five or six leaves, they should be hoed in the same manner as turnips, cutting down all the weeds from among the plants, and also thinning the plants where they are too thick; but they should be kept thicker than turnips, because they are in more danger of being destroyed by the fly: this work should be performed in dry weather, that the weeds may be killed. About six weeks after, the plants should have a second hoeing, which, if carefully performed in dry weather, will entirely destroy the weeds, and make the ground clean, so that they will require no farther culture. In the spring they may either be drawn up, and carried out to feed the cattle, or the beasts may be turned into the field to feed upon them as they stand; but the former method should be preferred, because there will then be little waste; whereas, when the cattle are turned in among the plants, they will tread down and destroy more than they eat, especially when they are not fenced off by hurdles. *Miller's Gard. Dict.*

COLLAR, the part of the harness that goes round a horse's neck.

Mr. Marshall, in his Minutes of Agriculture, says that after trying different experiments in various shapes; and finding that those formed with hair and tallow prevented a tender-shouldered horse from galling, but were tedious, expensive and complex; he therefore contrived one made with a wooden bolster; and instead of the bottom piece substituted an iron spring bow; and instead of spring pins had catches. The idea of a wooden collar arose, he says, from this observation, when a horse galls, it generally proceeds from some knot or lump in the stuffing. He prefers straw ones, for be the straw collars ever so hard, if they are smooth they seldom gall. The same wooden collars with great success, Mr. Marshall used for oxen, conforming to the construction of the shoulders of an ox, which generally are very much concave not convex. On experience, he strongly recommends the nine-pin collars as preferable to the bolstered ones for an ox, as they have this material advantage; whether the ox draws on a straight line or turns on a curve, they are equally easy on the shoulder. This is not so perceptible at plough, where it is straight forward, as at cart; when they draw at the turnings and where they obviously draw against the outer edge of the bolster. The nine-pin collars take less wood, are easier made, are stronger, and more tightly, and they fit a hollow shoulder as well as a full shoulder.

COLLAR of Brawn, is the quantity of brawn bound up in one parcel.

COLLATERAL Bee-Boxes. See the article **BEE**.

COLLEY Sheep, such sheep as have black faces and legs. The wool of these sheep is very harsh, with hairs, and not so white as that of other sheep.

COLLIFLOWER. See the article **CAULIFLOWER**.

COLONY, a number of people drawn from the mother country, to inhabit a distant place. And hence the ingenious Mr. White has applied the word to a stock of bees. See **BEE**.

COLT, a foal, or young horse.

Foals are separated from their dams after five, six, or at farthest seven months; experience having shewn, that such as are suffered to suck ten or eleven months, though usually larger and fuller of flesh, are not equal, in other respects, to those that are taken away sooner. After living six or seven months on milk, they are habituated to a more solid nourishment, having bran giving them twice a day, with a small quantity of hay, which is increased as they advance in age, and in this manner they are kept in the stable as long as they express any desire of returning to their dams; but when this uneasiness is over, they are turned into the fields, taking care never to do it fasting. An hour before they are turned to grass, a feed of bran and some water should be given them; nor should they be exposed to either severe cold or rain: in this manner the first winter must be passed. In May following they must not only be turned into the fields every day, but may lie in the open air till the end of October, taking care not to let them feed on the after-math; for by accustoming themselves to this remarkably delicate and succulent grass, they would contract a dislike to hay, which, together with bran mixed with barley and oats ground, should be their principal food during

during the second winter. In this manner they are to be kept till their fourth year, spending the days only in the pastures, during the winter; but both day and night in the summer. When they reach that age, they are to be taken from the pastures, and fed with dry meat; but in this change of food some precautions are requisite; as during the first week to feed them only with straw, and give them proper medicines against worms, which often trouble them from bad digestions and too rank grass.

At weaning young colts they should be kept in a clean stable, not over warm, which would render them tender, and too sensible of the impressions of the air. They must frequently have fresh litter, and be rubbed often with straw; but not tied or curried till they are three, or at least two years and a half old; for the roughness of this friction would give them pain, and their skin being too tender to endure it, instead of thriving, they would fall away. The rack and manger should not be too high, lest the necessity of lifting up their heads to reach their food should occasion them to carry their heads in that manner, which would spoil their chests. When they are a year, or a year and a half old, the hair on their tails should be cut, as the succeeding growth will be stronger and thicker than the former. When they are two years old, they should be separated, and the stone colts kept with the horses, and the fillies with the mares, otherwise the former would fruitlessly weaken themselves with the latter. At the age of three years, or three and a half, they should be broke, and rendered docile. In order to this, a light easy saddle should be put on their backs, and continue there three or four hours every day. They should also be used to receive the bit of a small bridle into their mouths, and suffer their feet to be taken up, and some strokes given on the sole, as if shoeing them. If they are designed for draught horses, a harness should be put on their bodies, and afterwards a snaffle bridle should be added. They should then be trotted on level ground, but without a rider, the person only holding the reins, and either the saddle or harness on their backs: and when the saddle-horse easily turns, and freely comes up to him that holds the rein, he should mount on his back, and dismount again immediately, without riding him, till he is four years old, as before that time the weight would be too much for him: but at four years old he may be ridden, and trotted at small intervals. *Buffon's Histoire Naturelle, tom. IV.*

COLT-EVIL, a distemper to which young horses are subject, consisting of a swelling in the sheath, occasioned by their having full liberty with the mares before they are able to cover them.

This disease may easily be removed at the beginning, by the use of warm fomentations, made of emollient herbs, &c. but if the swelling be hard and inflamed, bleeding and purging are both necessary; and it may also be proper to tie his yard up to his belly, making a hole for his water to pass free. *Gibson's Farriery, vol. II. page 168.*

COLTS-FOOT, *sole-foot, horse-hoof, or bull-foot*, the name of a very common weed, whose scaly stalks arise in February, bearing one yellow compound flower, which is succeeded by a hairy white down. The leaves come out later. They are shaped somewhat like a horse's hoof, and are downy underneath.

This weed, which delights to grow by the side of rivers, increases so fast by its seeds and rambling roots, every piece of which last will produce a new plant, though they have been broken by the plough, that it cannot be extirpated without much difficulty, and a considerable time. Carefully pulling up the roots every time the earth is stirred, or the least vestige of the plant appears, and preventing its running to seed, are the most effectual means of destroying it in arable land: and this is best accomplished by the horse-hoeing husbandry; but totally to extirpate it, the ground must be laid down long to grass. One of Mr. Lisle's neighbours almost destroyed it by two successive crops of vetches; and he himself is clearly of opinion, that it may be killed by letting the land lie a sufficient time under clover or rye grass; because, says he, the roots of the natural grass matting more and more every year, will in five or six years, so bind the surface of the ground, that the colts-foot will not be able to pierce through it, and will therefore die for want of air. He ploughed up broad clover in the beginning of July, and turned up the roots of colts-foot, in which he observed, between earth and air many little buds, shot forth, of the bigness of the midsummer buds in fruit-trees, probably to be the leaves or flowers of the next year; and at the depth of five, six, and even se-

ven inches; he remarked here and there a shoot of a callous body; like the root itself, from one to four inches long; perhaps destined to be future roots: he experienced that a winter's fallow will not destroy these roots, and that they cannot resist the effect of summer fallows, in which they are turned up; and exposed dry to the sun. It is therefore necessary to pick them as clean as possible, and burn them: for it is not to be supposed, that all the roots which are turned up in a summer fallow will wither of themselves: on the contrary, such of the buds at the joints of these as are buried under ground; will shoot out again if much rain falls, or the season be wet.

COMB, a measure of corn, consisting of four Winchester bushels; but in the fen country the comb generally consists of four bushels, and each bushel of eight gallons and a quart.

COMMON, an open piece of ground used equally by many persons.

The marquis of Turbilly has treated the subject of breaking up commons and waste grounds in so masterly a manner, that it will be necessary to give the substance of what he has advanced on this interesting subject, nearly in his own words.

"Upon the death of my father, says the marquis, which happened in the year 1737, I inherited the lands of Anjou, of which I am now going to speak. They lie contiguous, and form a pretty considerable extent.

"Hills and vales render the country uneven in many places; though in others, there are spacious plains, with several brooks, and a small river. The soil is of three kinds, bad, middling, and good: but this last is least frequent. Most of the lands being of a middling quality, are fertilized only by dint of care and manure: wheat grows on one spot, mellein on another, rye on a third; and sometimes it is necessary to sow these three different sorts of grain in the same field; so much does the soil vary: but, in general, we sow more ground with rye, than with any other corn. Buckwheat, barley, oats, hemp, flax, and other equally useful productions, are likewise cultivated in these parts. The vine prospers here very well, especially on the sunny side of banks and higher grounds: our wine, both red and white, is good; our fruit trees thrive well; and so does the white mulberry, of which I made large plantations some years ago. The oak, the elm, the beech, and other forest trees, grow extremely well in these lands. Such is the soil of this district: the climate is mild and temperate, as is the rest of Anjou.

"Three sides of this estate border upon immense tracts of uncultivated heaths, which spread through the greatest part of the province, and belong, some of them to the king, and others to different lords, ecclesiastical and temporal. However, the situation of my house, and of the chief village, is advantageous, being nearly in the center of the whole, and within about six miles of three pretty towns.

"Such was my estate when I took possession of it: not a quarter part of the land was cultivated, and even that very badly: the rest was either abandoned by the husbandmen, or had not been cultivated at all. Most of the meadows along the brooks and rivulets were become marshes, productive of scarce any thing but rushes. The vineyards were ruined, and the woods destroyed. A third part of the farms belonging to the principal parish where my seat is, were un-tenanted, for want of farmers to rent them. The inhabitants of this place were very poor, and did not, in general, raise corn enough of any kind to subsist them half the year: nay, such was their indolence, that they chose rather to stroll about and beg during the other half, than be at the pains of bestowing proper culture upon their land, which, with that culture, would have maintained them decently.

"This deplorable condition of my estate, which I have here represented fairly, without exaggerating any one particular, determined me, early in life, to read attentively all the most approved writers upon agriculture, and to observe carefully every improvement I met with in my travels. Even the campaigns in which I served did not interrupt these inquiries; for agriculture and arms never were by any means incompatible. Under these circumstances, I resolved to execute upon my own property, designs, which my knowledge of the place, concern for the unhappy situation of its inhabitants, and regret to see what small returns were made by so large an extent of ground, naturally suggested.

"I plainly foresaw that this undertaking must be a work of

of time; neither my fortune, nor the number of hands I could procure in the country, allowing me to go beyond the clearing and improving of a certain space every year. Some gentlemen of knowledge, judgment, and public spirit, to whom I communicated my thoughts, approved of them, commended my design, and exhorted me strongly to carry it into execution; representing, besides the advantage which would necessarily accrue to me, the general benefit which such an example might be of to my country, filled as it is with numerous tracts of uncultivated land. This last reflection animated me more and more.

"My first care was, to endeavour to extirpate the spirit of indolence, and consequent love of begging, which prevailed among my peasants in general. To this end, I gave public notice of my intended improvements, with a declaration, that I would constantly employ every man, woman, or child above eight years of age, who might not have business of their own to do, on condition of their leaving off begging. At the same time I ordered an account to be taken of such as were not able to work. These I afterwards examined more particularly myself, and found among them several who, though they were not fit for hard labour, were capable of doing many useful things, in which I accordingly employed them. By this means, my list of really helpless people was reduced to a small number, which I provided for, till their relations should be able to keep them by means of what they earned from me. A few, and only a few, of these poor objects, who either had no relations, or such as in truth could not help them, became a dead charge; though this soon lessened, and is now inconsiderable.

"An innumerable multitude of rabbits infested my land. Against these I declared open war; being determined absolutely to destroy them. This has already been several years a-doing, and is not yet entirely completed. Some of them still remain, sheltered in their burrows at the foot of rising grounds, and others make incursions from the neighbouring woods and warrens. However, they do me no great mischief now; and even then I drove them from the place where I wanted to work.

"In the month of June 1737, I begun my improvements with clearing some of the land near my house. This ground was so poor that no farmer would even attempt to make any thing of it, served only to feed a few stunted cows, and was over-run with briars, thistles, and broom, which, being cut up, and laid in heaps, from space to space, were burnt upon the spot, and yielded a considerable quantity of ashes. These were then spread, and immediately turned in by a single ploughing, lest their virtue should exhale. During the summer, this land was ploughed several times, different ways, in order to loosen it, and endeavour to destroy the weeds. I had bought for this purpose oxen, which are generally used for ploughing in Anjou: but my horses helped them, especially for harrowing. Here my poor peasants, men, women, and children, were employed to break the clods and pick off the stones; and as I had more dung than my arable lands required, I ordered about half the quantity that is generally used in other places, to be laid upon this ground, which was afterwards sowed at the usual time. This first trial succeeded, and the crop was very good; though most of my neighbours were of opinion that all my labour would be lost.

"In 1738, I undertook another piece of ground, adjoining to the former, and of the same kind. I began in March, proceeded as before, dunged it, and had equal success. The second crop of the former spot is still more plentiful. This summer I gave a thorough fallow to ten acres which had long been under corn, and sowed part of them with hemp and flax, for a purpose which will be mentioned hereafter. I likewise recruited my vineyard, and drained my meadows. Numbers of day-labourers were employed in cleansing the rivulets and brooks which run through them. In the winter of this year an accident happened, which had like to have overset my whole undertaking. The oxen which I used for ploughing, and which were grown lean, it was supposed through labour and fatigue, were on a sudden covered with vermin, which eat into their flesh: several remedies were applied, but in vain, the vermin re-appearing in a few days. We knew not to what cause to ascribe this disorder, which was destroying animals without whose assistance I could not proceed: besides which, the loss would, in itself, have been considerable. They had hitherto been fed with hay only; though

the custom of the country was to mix it with an equal quantity of wheat-straw. As I had not yet a sufficiency of this last, I bought some, gave it to them mixed with hay, and allowed them oats from time to time when they had been hard worked. This mended them a little: but they did not recover entirely, or get rid of their vermin, till they fed on green grass and lay out of doors.

"I begun this year to make new roads and causeys across my meadows, marshes, and rising grounds, for the easier conveyance to and from my fields; the old ways being often impassable in many places. This has been a very long and expensive work; nor is it yet quite finished. I also bought at this time a number of sheep, which have since increased considerably; for, notwithstanding the great extent of this uncultivated land, where many of them might easily have been fed, none were ever kept upon it before. The people of the country thought they could not thrive there, on account of the marshes, and of a plant called white root, very prejudicial to them, found in several parts of the lay-grounds and commons. Most of these weeds were pulled up at a small expence; and the sheep, who were fond of this herb, eat up the rest, which was so little that it could not do them much hurt, though some of them were sick with it. The constant feeding of the sheep, and their dung, afterwards completed the destruction of this noxious plant, and brought up good grass in its stead. This shews how farmers may often get rid of any such bad weed.

"In 1739, I took the next contiguous land, going round my mansion: a method which I have always followed; so that my improvements have been, from year to year, more and more distant from my place of residence. The soil I now fell upon was tough, strong, and only thin grass grew upon it, with here and there a few brambles and other wild productions, which were soon cut up. This ground was broken up only with the plough: some dung was laid upon it, and I sowed it directly with winter oats, which succeeded very well. My improvements of the two last years yielded plentiful crops, not only of corn, but also of hemp and flax. These last were dressed and given to the women and girls to spin; paying them different prices, according to the fineness of the thread. They applied themselves to their work, and by degrees became perfect in it. By this means I accomplished my design of finding employment for these women and girls all the year round, and afforded them the means of procuring an honest livelihood, as well as to those whom age or infirmities rendered incapable of working abroad.

"The business of the field was always preferred in the seasons proper for it, and when the weather permitted; keeping in my eye Cato's advice, never to work within doors, while there is any thing to be done without, nor to do that in fair weather, which may be done in wet. I have continued this spinning ever since; and have allotted for the growth of hemp and flax particular spots, which I have inclosed with hedges and ditches, and kept in good heart and with fine tilth. They have yielded plentiful annual crops without being rested; only dunging them every other year; for hemp does not impoverish the ground when it is properly cultivated. My vines, meadows, and ways were not neglected.

"In the beginning of this winter I gave my oxen hay mixed with an equal quantity of rye-straw, not having wheat-straw enough to answer that purpose. This succeeded to my wish. My oxen continued in perfect health, free from the vermin I mentioned before, and in better plight than those in the neighbourhood, which were fed with hay and wheat-straw. I have continued to give them this food as long as they lie within doors, and find it answer extremely well. During this time they have no corn, even though they work; and I do not find that this suppression of their otherwise usual allowance of oats, renders them at all less hearty and vigorous. This quality of the rye-straw may be of great advantage in countries where oxen are used for ploughing.

"In the year 1740, I was obliged to make a considerable addition to my number of servants, and stock of cattle of all sorts in proportion to the increased extent of my improvements. It may perhaps be thought, that so many servants would eat me out of house and home. This I had guarded against from the beginning. All those employed in my husbandry lived by themselves, in some of the out-houses, where they had their own kitchen, and a certain stated allowance

lowance, suited to their usual manner of life ; so that they had no sort of connections with the others, whose more immediate business it was to attend me.

" The land which I improved this year was covered with heath, broom, and furze, which had grown very thick and high. In the spring, when the weather was dry, I set fire to this surface, after taking the due precautions to hinder the flames from spreading too far. The whole burnt very well, and I was in hopes of being able to plough up this ground without paring off the turf, as I had done with my other land the year before. This would have been a considerable saving ; especially as the ashes were ready spread. But I should have considered that different lands require different treatment. Ploughs stronger than usual, were made on purpose for this work ; but the roots of the furze and broom, which had resisted the fire, broke them ; and though I doubled the number of my cattle for draught, several of the oxen were ruined by this hard work, in which I persisted with too much obstinacy. In vain did I plough it over and over, and break every clod both before and after sowing it ; the broom and furze were not destroyed, but made new shoots every where : the land continued unkindly and sour, and the oats which I sowed in it yielded scarce any crop ; in short, repeated ploughings and dunging were necessary during three years, before it could be brought to a good tilth, or those noxious plants be quite extirpated. I came badly off in this experiment : but my former improvements, which I had continued to manure and sow, luckily produced an abundant crop : that of the last year yielded a good quantity of wheat, which kept up my establishment, though it did not compensate for the loss I now sustained. However, this disappointment did not discourage me. It raised the laugh of the whole country at my expence ; especially of those who had foretold from the beginning, that I should not succeed. I gave them the hearing, and only resolved not to fall a second time into the same error.

" This year I established a nursery of fruit-trees, and also of forest trees from other countries. This nursery which succeeded very well, was of great advantage to me afterwards, to fill up the different plantations which I made as my improvements extended. I likewise repaired my woods, which had formerly been destroyed by cattle and deer. I surrounded them with ditches planted with hedges, in order to bring them into regular yearly cuttings ; to which end I grubbed up such trees as were stunted in their growth, and filled every empty space, either with young plants, or the seeds of others, according to the nature of the ground. By continuing to do this every year, my woods are now in excellent order, and afford regular cuttings, at a small expence of keeping the fences in repair.

" In 1741, I had the same kind of land to deal with as the year before ; but took care not to commit the same fault. Each day's cutting of the heath, broom, &c. was burnt, with proper precautions, as the workmen advanced, and the whole surface was dug by hand as it was cleared. By this means, the ashes of these plants preserved their fertilizing quality, and their roots were pulled up. Women and children took the earth from off these roots, and turned them, whilst they were drying in the hot weather. These were also laid in heaps from space to space, and burnt upon the spot, where they yielded some ashes, which were spread, and immediately buried with one turn of the plough.

" During the summer, this ground was ploughed several times ; each time in a direction different from the former. My cattle were but little fatigued with this work : the heath, broom, &c. was almost entirely destroyed, and the sourness of the land was in a great measure cured. I had then begun to make composts, which were mixed with the dung of the stall and stable, and proved of singular benefit. With their help, I was enabled to manure my newly broken up-land sufficiently ; that is to say, to lay upon it half the quantity that is generally used of dung for the common run of lands. I sowed this piece with rye, which yielded a plentiful crop. The crops from my former improvements, which I continued to sow without resting them, were likewise very good this year, excepting that of the last, which was also under rye, and yielded but a middling produce. My vineyards were now brought into as good order as any in the province ; and I continued draining my meadows, and making roads and causeys.

" The war then calling me into Bohemia and Bavaria, I

forefaw that I should be absent some time, and consequently not able to spend part of the year in the country, as I had used to do ; to give directions to my people, and see my orders executed. Under these circumstances, that my improvements might not stop, I gave the direction of the whole to an intelligent servant, who had lived with me a long while, and was married to an excellent housewife : and to interest him the more in the future success of my undertaking, I agreed to allow him half of the profits of every kind : subjecting him to this only restriction, that he should not impoverish the ground by too many crops. In this state things went on till the end of the year 1748.

" In the mean time new pieces of land were broken up every year ; but not so extensive as the former ; the expence of my campaigns not permitting me to lay out upon them so much money as before. I even straitened myself, not to interrupt the progress of my improvements : which, in general, succeeded very well. I also revived an old method of breaking up land, by cutting off the surface with a paring mattock, and then burning it. See the article BURN-BAKING.

" During the whole of this time, I was but two years together without visiting my estate, where my presence was then very necessary. In all the other years, I gladly accepted the leave which was given me to see how my works went on ; though I sometimes did not stay above a fortnight among them. However, this was enough to give an eye to every thing that was doing ; which is of great consequence in undertakings of this kind.

" Peace being restored, I resumed the personal guidance of my affairs in the beginning of the year 1749, and placed my old servant in a farm which I had to let, where his profits sat him down at his ease. Though he was extremely faithful, and my improvements were carried on very well, yet I found that, for want of due care and attention at certain times, the crops were not equal to what they had been under my immediate direction : a circumstance which plainly shews, that a work like this never thrives so well as in the hands of the owner himself.

" I now resolved to pursue my improvements as before the war, that is to say, to break up larger tracts of ground every year, than had been done of late. Most of my yet uncultivated lands were, and had been from time immemorial, thick covered with high broom, heath, fern, &c. and experience had taught me that these were not to be broken up with the plough alone.

" Of all the methods which I tried, none seemed to me, as I said before, so good as the paring-mattock and burning. I therefore fixed upon this, and, in consequence, sent for the workmen I had formerly employed in trials of this kind : but their number not sufficing for the extent of ground which I proposed to break up this year, I sent for others from a distance, and was weak enough to let these last persuade me to contract with them at a set price, for paring the whole surface. I agreed to give them even more than they ought to have had for doing the work ever so well ; for I was not yet thoroughly acquainted with the nature of this business. They began it in March ; and to earn their money the more easily, or rather to rob me, only skimmed off the mere surface, without hardly touching the roots of the plants, which they should have cut off. When this work was done, as they called it, for the burning part did not belong to them, they immediately came to me, and asked for their money, which I simply gave them, not suspecting the cheat, but only thinking they had earned it very soon. When the turf of their cutting was dry, I ordered it to be laid in heaps, and burnt. The small quantities of ashes which it yielded, made me suspect the roguery : but when I found that the roots in the earth broke some of my ploughs, in cutting only a single furrow to cover the seed, and that there was no clearing it of clods, I was thoroughly convinced that I had been the dupe of these people, and that this paring would be of little service. The wheat sowed in this ground rose indeed pretty well, and looked tolerably during part of the winter ; but not being able afterwards to strike through the crust formed by the remaining matted roots of the plants, most of it died, and the little that remained scarcely returned the seed : nor could this land be recovered till the next year, even by ploughing, breaking the clods, and dunging.

" The bad success of this experiment, upon which a great deal of money had been thrown away, tried my patience, but did not discourage me. My neighbours

began anew to exclaim against my projects, as they called them; and numbers of those people who are determined at all events to oppose every novelty, be it right or wrong, were pleased to vent their sarcasms at my expence: I let them talk on. The roguery of the people who had last pared my ground did not hinder me from still thinking that this was the best way of breaking up new land, especially heaths; and the event has shewed that I was right. This check, which was the last which I received, made me resolve to take my measures better for the future.

"The rest of my improvements yielded very good crops this year, during which I continued to mend my roads and meadows. These long winded works, for which only a certain space of time, and a certain sum of money, could be allotted every year, have been continued ever since, and indeed are not yet finished. I likewise bought this year several hives of bees; though I had some before. These useful creatures have multiplied exceedingly; especially in a little garden, where my chief apiary is, situated between meadows and heaths, of the flowers of which they are remarkably fond. Though these industrious insects thrive perfectly all over the country I am speaking of, yet the inhabitants of these parts not only have not a tenth of the number they might keep, but ignorantly follow the old barbarous custom of destroying the bees, when they want their honey, instead of only taking part. See the article BEE.

"I did not agree by the piece for breaking up the land I intended to improve in the year 1750, lest I should be again deceived; but hired proper labourers by the day. They began their work in March, and finished it about the middle of June; cutting all the way deep enough to go under the crust, or net-work, formed by the roots beneath the surface; for I took particular care to see that this was done. When the turf thus pared, to the thickness of about four inches, was dried, piled up, and burnt in heaps from space to space upon this ground, it yielded a considerable quantity of ashes, which enriched the soil for a long time. Wheat was then sowed, and the plough easily turned up the furrow which covered the seed. Women and children easily broke the clods of this ground, which was thereby at once brought into good order; the roots of all the wild plants having been effectually cut through, and their seeds destroyed by the fire. My wheat, by this means un-incumbered with noxious productions of any kind, flourished well, and yielded an excellent crop; as also did such other parts of my land as were under corn. The success of this year revived my hopes. I now perfected my method of making artificial dung, which, as I have already observed, proved of infinite service; and, for manuring my more distant lands, I built upon them perpetual kilns, which have always supplied me with a sufficient quantity of ashes.

"This year I began to plant white mulberries, in order to feed silk-worms, and make the inhabitants acquainted with the management of them. I have since continued to make plantations of this kind every year, and find them answer perfectly well, especially in light soils. Several of them are an useful embellishment to proper parts of my improved lands, and I have alleys of them, which, though not suffered to run up high, form a very pleasing prospect.

"In 1751, I again succeeded perfectly well in my new method of paring and burning. All my cultivated lands now yielded very good crops: and that in particular which I had broke up last year, and since dunged properly, that is to say, with half the quantity commonly used upon ground in general, produced more than any other equal space had yet done. From this time I continued to dung all my grounds which were broken up in this manner, every alternate year.

"My improvements were now become so extensive, that I was again obliged to increase the number of my servants, and of my ploughing cattle. The same thing happened more than once after this; but I shall not mention it any more. My cattle too, of different kinds, had multiplied so much, that I had no longer room for them in the old farm yard, or buildings belonging to it, but plainly saw, that if my improvements were enlarged every year in the manner they had hitherto been, I should soon want more yards and more buildings, to keep them in. I accordingly marked out proper places for this purpose, and drew plans for more spacious buildings.

"As the cattle in this country are small, I bought some of a larger size in Poitou (from whence we generally have our working beasts,) and particularly a fine bull, to try if I could mend our breed, and thereby have of my own oxen strong enough for the plough; by which means I should save the expence of buying them elsewhere. I have not yet succeeded in this, so far as I could wish; probably because my pasture is not yet good enough. However, my bullocks, proceeding from this race, are much stronger and bigger than those I had before, though not large enough to be yoked to the beam, but only before or with others.

"The ground which I broke up in 1752, was pared and burnt in the same manner as that of last year, and produced an equally good crop. My other corn lands did the same; and I have since continued, and still continue, at the time of my writing this, to break up a parcel of heath, or other waste-ground, every year. The success has answered; so that my improved lands now yield me every kind of corn which this country produces. Turkey-wheat, buck-wheat, and millet, have done extremely well in some parts of them; and so have flax, hemp, and other productions suited to the different qualities of the soil. In some places I have sowed, at different times, several sorts of trees, such as the oak, the beech, the chesnut, the fir, and others, all of which thrive wonderfully. I have likewise planted new vineyards, and find them answer perfectly well. All these trials convince me more, and more, that the very best way of preparing land, is by burning it, as I have already said more than once. Those who were formerly the readiest to blame my undertakings, now see their error, and commend them.

"During this same year 1752, as well as in the course of the following, I drained several marshes, and improved other pieces of uncultivated ground, which not being of the heath kind, or proper for paring, were broken up, and fitted for their respective crops, whether of corn, or of other plants, as is more fully related in the second part of this account. I likewise sowed in these, as I had done before in other places, trees of every kind, some of which have succeeded, and others failed, according to the soil, and the manner of preparing it. This also will be more fully noticed hereafter, when I shall speak particularly of the different methods of raising trees from their seeds: and of the means of obviating the three chief difficulties which must of necessity be guarded against or removed, before one could properly set about breaking up any sort of ground; these are, water, stones, and large roots; each of which I have found it necessary to get rid of, before I could rightly begin any of my improvements.

"I endeavoured this year to make some progress towards perfecting my instruments of husbandry; my new buildings went on according to the plan I had laid down, and were extended from time to time, in proportion as the products of my enlarged improvements and the increase of my stock of cattle, required more room. I likewise tried to mend the breed of horses in this country, where their chief fault is, that they are too small.

"My sheep were also too small a size, and yielded but little wool, which indeed is the case throughout this province. I therefore got from Lower Poitou, in the year 1753, two fine rams, of the large kind, called Flemish, by which means my lambs are much stronger than any other in these parts. Several of the males are almost as large as their fires, and I have given some of them to my neighbours for rams. They have produced a bastard breed, which increases apace, and, though not so large as the Flemish, yields more and better wool than our former breed. I got rid of all my old sheep by degrees, and have now a well-sized stock; nor do I doubt but that if I could conveniently have purchased a whole flock of these large sheep, their breed might have been preserved without degenerating, and increased so as to supply the place of our present inferior species: for our uncultivated lands would feed a much greater number of sheep than we even attempt to raise.

"In 1755, I discovered lime-stone upon my own land. This proved a considerable saving; for I had hitherto been obliged to fetch my lime from a distance of near twelve miles. This stone, if properly searched for, may often be found in places where it is not suspected to lie. It is easily known, by putting a piece of it into the fire, till it be calcined, and then dissolving it in water. This discovery, in consequence of which I built a proper kiln, has enabled me

to carry on my buildings with less expence than before; and is of signal service in affording an excellent manure for my land.

" I began this year to give premiums for agriculture to the inhabitants of my estate. They were instituted the year before; and I had long used my best endeavours to inculcate a general love of industry, and a relish for improvements. My success had induced several others, both landlords and farmers; to follow my example, as well in amending their already cultivated lands, as in the breaking up of new grounds. I assisted them in their undertakings, giving instructions to some, lending seeds to others, and money and tools to such as were honest, and wanted them. The better to encourage them all, I had given rewards every year to those who distinguished themselves most, and allowed my tenants sixteen shillings for every acre of new ground broken up by them: a regulation which still subsists.

" To fix these people in the industrious disposition to which I at length had brought them, no method seemed to me more proper than to take them on the weak side of almost all mankind, interest and vanity. Accordingly, I notified in the month of January 1754, that I would distribute every year, beginning on the next ensuing festival of the Assumption, two premiums for agriculture; one, to the person who should raise the finest crop of wheat, and the other to him who should have the best field of rye. Each of these premiums consists in a sum of money, not inconsiderable for the country where it is given, and a silver medal, engraved for the purpose, of the size and value of a crown piece. These were, I believe, the first premiums ever proposed in France for this most useful object: though many have been given for much less interesting concerns. On one side of this medal is a sheaf of corn, with two sickles, a scythe, and a flail; over which are the words, *Premium for Agriculture*, and underneath the date. On the other side are my arms, with this inscription round them; *To excite to industry the inhabitants of*, &c. I would not put the goddess Ceres of the ancients, or any emblematical figure upon this medal, because, in the first place, the ignorant peasants would not have understood its meaning, and in the next, some of them might perhaps, hereafter, take it for the representation of a saint, and honour it as such; by which means, what I intend only for an object of utility, would become a source of superstition or idolatry.

" A candidate for these premiums must have at least two acres of land sowed with either wheat or rye: they are given to the finest crop as it stands to avoid all tricks; and if two crops are deemed equally good, the worst soil has the preference. When both the crops and the soils are alike, the largest extent of ground is entitled to the reward. The inhabitants of the place, in general, meet at the parish church on the day appointed; and, after divine service, choose from among themselves five who are not candidates, to inspect all the fields of corn, and mark those which they think the finest. On the next Sunday or holiday, they make their report to the same assembly. If any one complains that his corn has been unjustly passed over un-noticed, proper persons are immediately sent, to examine whether the complaint be just. The assembly then appoint the same five as before, or others if they please, to go and inspect again, with the utmost care, the fields which they had marked, and to judge which two of them, one of wheat, and the other of rye, best deserve the premiums. On the next Sunday or holiday they declare their opinions to a general assembly of the parishioners, as before; and, if no objection be made by any of those whose corn has been marked, this assembly adjudges the premiums accordingly: but if any one of them appeals, other proper judges are immediately chosen, and directed to inspect the spot. On the next Sunday or holiday, till which the decision of the premium is, in this case, of course put off; these last examiners make their report, and the matter is then determined. All the people thus sent by the assembly, are paid at my expence. In consequence of the decision of the inhabitants, the premiums are delivered publicly on the feast of the Assumption, after the service at church is over. Those who win them, wear the medal, for a year only, fastened with a green ribbon to a button-hole of their coat, and have, likewise for that time, a distinguished seat in the parish church. These marks of distinction cease at the end of the year, when others succeed to them;

but the medal remains the property of the person to whom it was adjudged. He may dispose of it as he pleases; yet, though he is no longer allowed to wear it on the outside of his cloaths, there has not been a single instance of any one's selling his medal. They all keep it as a badge of honour.

" These rewards have been productive of so much good, and have raised so extraordinary an emulation among my tenants, that I cannot but advise every gentleman to practise the same method upon his estate. I intend to institute some others, for different productions; and as I am far from having a sufficient number of people to manage all my lands, if the whole of them was under culture, I have long thought of giving gratuities to such as shall have a child within the first year of their marriage, to continue this allowance to them so long as they shall have a child from year to year, and to allot a pretty considerable sum for the family which shall have most children. Some may, perhaps, think these encouragements for propagating the human species odd, and even superfluous: but they will be of a different opinion when informed, as they may be by the ministers of most country parishes, that many peasants are unwilling to get children, or at least do not choose to have more than a very small number, when they might have a numerous offspring. If my abilities were equal to my will, I should already have formed all these useful establishments. It is generally allowed, and experience has particularly demonstrated it upon my estate, that an increase of culture produces an increase of inhabitants; and that wherever there is room for two, with the means of subsisting them, a marriage will ensue: but at the same time that this means of increasing population is encouraged by a more extensive culture of the earth, I see no reason why proper methods should not be used to induce men likewise to concur in the same laudable end.

" Ever since the year 1756, I have continued all my undertakings, and with the same success as before. Those who saw the condition of my estate when I first came to it, in the year 1737, now scarcely know again a single spot of it; so much is the face of the country changed. My mansion-house, which was formerly surrounded with dreary wastes, vast commons, and unbounded heaths, now stands in the middle of well cultivated fields: my improvements are become considerable both for extent and value: producing all sorts of grain, and natural as well as artificial grasses. I have dispersed in them all kinds of fruit-trees, and divided them into fields of proper sizes, separated by good ditches planted with quick hedges. Alleys of limes, poplars, white mulberries, chestnuts, and various other trees, besides being a considerable embellishment to the whole, afford convenient passes from one field to another, yield food to cattle, and are sown from time to time. I turn every thing to profit; even my driest soils. Many of my marshes are drained, and yield good crops. All my meadows by reason of their great extent, are not yet brought to the state in which I wish to see them; though a great part of them now produces excellent hay. I have mowed some of them twice a year, and hope by and by to do the same to others; for I intend to water them all, by making dams and sluices in the brooks and rivulet which pass through them.

" My vineyards are in good order; and my woods, which are now in regular cuttings, thrive perfectly. Some of these, which I have raised from the seed, have grown so prodigiously, that a stranger would think them much older than they really are. I have made some large reservoirs of water, and several ponds, entirely new, besides repairing the old ones. All these have succeeded, and yield good fish. A quarry of mill-stones, formerly abandoned, now turns to good account, and I have discovered several quarries of free-stone.

" I have been obliged to make several bridges over the brooks and rivulets which divide my meadows and marshy grounds, and have carried my roads as far as my improvements extend. Some of these roads lie over hills, which could not be avoided; though others have been cut through, at a great expence. Most of my out-houses, which are pretty spacious for all my cattle and all the produce of my land, with proper buildings for poultry, barns, granaries, &c. are finished; and I have built farm-houses with the stones which it was necessary to take off the lands, in different parts of my improvements, and settled in them young men, who are now married, and have children. Though

Though my barns are very large, and not few in number, I have the pleasure to find that they would not contain all my last year's crop of corn: a satisfaction which I hope to enjoy still more amply in the next and following years.

"Thus my estate, which formerly yielded scarce any thing, now affords every necessary for food and raiment. When there I can, truly speaking, keep a very good table, and be decently clothed, with only the produce of my own improvements. I have no occasion to buy any thing except salt, sugar, and spices. My farmers have followed my example, so far as their means, and the helps that I have given them, have permitted.

"These improvements have, undoubtedly, cost me a great deal of money; but my income from them will soon be proportionably increased; besides which, it is proper to observe, that few lands will require so great an expence to break them up, as mine have done; owing to the uncommon stubbornness, inequality, and unkindness of the soil: nor will it often be necessary to cut through hills in order to make roads, to lay causeys over quaking bogs, or to erect so many new buildings: though, if even all these difficulties should occur, I would still advise gentlemen to undertake the improvement. If they follow the directions here given, and profit by my errors, so as not to commit the like, I can assure them of success, at a much less expence than it has cost me, who have thoroughly paid for my apprenticeship. I can also promise, that they will lay their money out at better interest, and on better security, in this, than in any other way, besides which, they will have the heart-felt satisfaction of contributing to the prosperity of their country, to the increase of population, and to the enriching of others, at the same time that they enrich themselves.

"I have already said, that when I began my improvements, two and twenty years ago, a third part of the farms in my parish were untenanted, for want of farmers who would rent them; that most of the inhabitants of my estate were very poor, and did not, in general, reap corn enough to support them half the year; that they were grown so indolent, that rather than cultivate their ground, which would have afforded them a maintenance, they chose to beg, like vagrants in the neighbouring districts. Now their situation is very different, and they are no longer in that deplorable condition. They are become industrious, live by their labour, and beg no longer: they would even be at their ease (a happiness which I shall do my utmost to procure them), were it not for obstacles beyond my power to remedy. The parish now reaps more corn than it consumes; so that the farmer here is enabled to sell at the very markets where he used to buy. All my farms are tenanted; not a house on my estate is empty, and if I build a new one it is immediately filled: in short, the number of inhabitants in this parish, for I have an exact list of all of them, is double what it was in 1737. Such is the history of my improvements, and such are the effects with which they have been attended." *Memoir sur les Defrichemens, par. II.*

Burn-beating, or burn-baking, has been long practised in some parts of England; but in many others, is totally exploded, as destructive to the land, which it certainly is, as commonly managed, for it has been customary to burn-bake chiefly downs, and other such land of a very thin staple, from whence the fire carries off so great a part of the soil, that such burn-baked land is afterwards reputed to be quite barren, and of no use. And for this reason, the owners required great fines, for granting liberty to burn them; which the tenants willingly paid, because they got a great deal of money by it; for the burning, which is not very expensive, forces the land so much, that they were sure to obtain several great crops from it, and they continued to crop the land, with robbing crops of wheat and other corn, till the land was quite impoverished, and would at last yield none sufficient to pay the small expence of cultivation; for it has been long remarked of most farmers, that they are so prejudiced in favour of tillage crops, without allowing the land proper change of crops, rest, or manure, that they continue plowing every year till the land is quite impoverished; as in the present case of burn-baking, liming, &c. The very ingenious M. de Turbilli, pursued a quite different method: he took only a few crops after his burn-baking, and as soon as he perceived any abatement in the fertility of his land, he applied proper dressings of manure, which restored it, and to this judicious practice his great success is to be ascribed. If the

owners of land would oblige their tenants to pursue the same method, instead of prohibiting entirely their burn-beating, it might in time become a general system in husbandry, very much to their own and tenants advantage, and to the great benefit of the public.

The difficulty which this gentleman found in sowing the proper quantity of seed upon his newly burn-baked lands, may be entirely removed by sowing them with a drill-plough, which can be managed with great ease in such a light soil, and where is no obstruction from either stones or roots. The occupier, in this case, would be under no apprehension of damage to his crop from weeds, which deters them from allowing the rows of corn a proper distance in other lands; and if the rows are sown at such a distance, as to admit a small plough to come between them; or if only eighteen or twenty inches distant, a hoe, with several tines in it, would cultivate the intermediate spaces to great advantage, and at the same time would so much break the clods, and pulverize the soil, that it would be much enriched by it, and save great part of the expence of the tillage for the next crop. The spikey roller would also be very serviceable, to break the clods and half-burnt turfs, before the land is sown, much more expeditiously, and at a less expence than beating and breaking them by hand.

"The marquis observes, that, as to the little freeholders and farmers, who have but a few acres, and after having grubbed, cleared, and burned them, in the manner above-mentioned, labour them by the strength of their arms, with the pick-ax, shovel, spade, or other instrument, and wish to sow in one of the above recited methods; they must take care to mix the ashes well with the soil, and to carry off all the stones and roots. These are they who will in proportion reap the most corn the first year, as digging stirs the ground much better than ploughing. Were it possible to cultivate all thus with the spade, it would produce a great deal more."

This is undoubtedly a just observation, and the reason of the spade tillage being superior is, that the spade breaks the soil most, into the smallest parts, and also goes deeper in it than the plough does in the first culture. Every means therefore of pulverizing the soil, and deeper than is commonly done at first in burn-baked lands, should be adopted. The spikey roller will be very serviceable here: for the earth having been dried by the fire, this roller will make the surface very fine; and so it will the soil below, by ploughing it up, and drawing the roller two or three times over it, especially if the land is harrowed between the rollings, to bring up the clods; or if that is not sufficient, by alternate ploughing and rolling. In this manner this dry soil may be broke, even more effectually than by digging with the spade, and at a much smaller expence.

COMPOST, an useful sort of manure, consisting of earth, dung, lime, clay, &c. according to the nature of the soil, well mixed and rotted together, till it forms one united mass. See **DUNG-HILLS**.

CONE-WHEAT, a species of wheat, called in some parts of Somersetshire, blue ball. Some of the ears of this wheat have awns, and others none. See **Plate IV.** fig. V.

CONIFEROUS, an epithet applied to such trees as bear cones, as the fir, pine, cedar, &c.

CONSOUND, the same with bugle. See the article **BUGLE**.

CONSUMPTION, a disease incident to horses, consisting in a waste of muscular flesh, attended with a slow fever.

When a consumption proceeds from a defect in a horse's lungs, or any principal bowel, the eyes look dull; the ears and feet are mostly hot; he coughs sharply by fits; sneezes much, and frequently groans with it; his flanks have a quick motion; he gleans often at the nose, and sometimes throws out a yellowish curdled matter, and he has little appetite to hay, but will eat corn, after which he generally grows hot.

As to the cure, one of the principal things is bleeding in small quantities, a pint, or pint and half, for some horses is sufficient, which should be repeated as often as the breath is more than ordinarily oppressed. Pectorals may be given to palliate present emergent symptoms; but as dissections have discovered both the glands of the lungs, and mesentery to be swelled, and often indurated, the whole stress lies on mercurial purges, and the following ponderous alteratives, given intermediately.

Take native cinnabar, or cinnabar of antimony, one pound,

pound, powdered very fine, and add the same quantity of gum-guacum and nitre: give the horse an ounce of this powder twice a day, wetting his feeds.

The spring grass is often extremely serviceable, but the salt-marshes are to be preferred, and even to be more depended on than medicines; for great alterations are thereby made in the blood and juices, and no small benefit arises from open air, and proper exercise.

But it may be worth observing, that a horse frequently relapses after appearances of amendment; when a yellowish gleet, or curdled matter, runs from his nose, and he grows emaciated, is much addicted to sweat, heaves much with a reduplicated motion, and has a short rattling cough; under these circumstances there can be little hopes of his recovery, or any future service from him, consequently to save farther expences, the best way would be to dispatch him as an incurable. *Bartlet's Harriery*, p. 76.

CONVOLVULUS, the same with bind-weed. See the article BIND-WEED.

COOM, the foot that gathers over the mouth of an oven; also a composition of tar and grease, with which the axle-trees and boxes of the wheels of carriages are daubed or smeared over, in order to lessen the friction.

COOP, a tumbrel or cart enclosed with boards, to carry dung, sand, grains, &c. which would otherwise fall out.

COOP likewise signifies a pen, or enclosed place, where lambs, poultry, &c. are shut up in order to be fed.

COPPICE, low woods, cut at stated times for poles, fuel, &c.

"If you are to plant a coppice, says the ingenious Mr. Lisle, it is a good way to set your plants in trenches, as one raises quickset hedges, and not to sow seeds, for they are tedious in coming forward, and will tire one's patience in weeding them. I would not set above four plants in twelve feet square, and at regular distances, so that the benefit of ploughing might not be lost; and then at six or seven year's growth I would plash, by laying the whole shoot, end and all, under the earth in the trenches, which would not therefore be choaked, but shoot forth innumerable issues: this, by great experience, oak, ash, hazle, and withy, will do.

"In our parks we never set less than an hundred plants in a double chased lugg; and if the earth turned up such rubbish and stony stuff that the edge of earth on which they are to plant, is too narrow for a double chase, then they always set eighty plants on a single chase in a lugg.

"I observe the sedgy grass comes not up in felled coppices the first summer; consequently the young shoots have a year's start of that grass; the next summer the sedgy grass comes up, and grows ankle high, equal with the two year's shoots: but what harm can it then do to the wood? The third year the sedgy grass dies, and you see no more of it. I speak this, in answer to the countryman's objection, who pleads for putting some sort of cattle into coppices to keep down the sedge, which he pretends otherwise will choak and damage the plants. I have experienced this to my cost.

"It was May the sixth, in the year 1701, that I bought some yearlings; and asked the farmer, if I might not put them in the coppice till midsummer: the farmer said, not yet, by any means, for fear they should be oakered, that is, lest they should bite off the oak-bud before it came into leaf, which might bake in their maws and kill them; but after the oak-bud was in leaf, it would be safe enough. The higher coppices are fit for yearlings, and the coppices of the last year's growth for hog-sheep in winter. My shepherd said, what the farmer observed as to the oak-bud was true; but he thought that the year was so backward, that they were not yet come out, and so there could be no danger at present. Farmer Elton said, his father had lost abundance of yearlings by the oak-bud, by putting them into the coppices while that was out. I have since experienced and remarked the same.

"It is a common saying, that calves will not crop in woods: but I put six calves in my woods, in November, which very much crompt the yearling shoots. All husbandmen I told of it very much wondered at it; but the reason to me was clear, viz. on first putting them in there came three or four days hard frost, with a shallow snow, and a rime that laid on the bennetty grass, so that they could not

come at the ground, but only met with briar leaves, of which, though I had plenty, they were but thin diet to depend on altogether; yet together with other pickings, would have been a noble maintenance for them, if they could have come at the rowet: this straightness of fodder brought them to the necessity of cropping the young shoots, which they afterwards continued to do, having got the habit of it, and finding, when the weather came severe, the shoots to be toothsome, though the rowet in the coppices would have been sufficient.

"For a general rule, newly weaned calves are less hurtful to newly cut spring-woods than any other cattle, especially if there be abundance of grass; and some say, colts of a year old will do no harm: but the calves must be permitted to stay a while longer, and surely the later you permit beasts to graze the better.

"Letting coppice-wood grow to sixteen or seventeen years growth is of great service to young heirs, because by so many years growth their backs are case-hardened, and able to withstand the cold, when the coppice is cut, and they must stand naked; whereas, when coppices are cut at ten and eleven years growth, the barks of the young heirs are so tender, that they are starved with cold air and winds. Ivy itself, says Evelyn, the destruction of many a fair tree, if very old, and taken off, does frequently kill the trees by a too sudden exposure to the unaccustomed cold.

"When coppice-wood is of fourteen or fifteen years growth, it will yield a better price in proportion than young wood, because it will be applicable to more uses, and particularly in the cooper's business; for he will use the withy and some of the ash for hoops and wine hogsheds; another part of the ash may serve for prong-staves, rake-staves, and rath-pins for waggons, and the rest may be parcelled out for hurdle and flake-rods.

"Oak stems of fourteen years growth are, in my woods, which in a great measure consist of them, as high as the ash or withy, and measure more in the diameter; for oaken stems are stronger at root, and will hold growing longer than ash, withy, or hazle. When hazle grows spriggy in the body, and shoots forth from the sides of the back, it is a sign that it has given out, and done growing at the top.

"Coppice-wood, in hedging and hurdling, wears much better and longer if cut between Michaelmas and Christmas, but sells best in faggots, if cut between Christmas and Lady-day, because it shrinks less, and is much swelled, and looks best to the buyer. The method at Crux-Easton, and the hill country adjacent, is only to oblige the buyers to rid the coppice by Midsummer; they think the coppices are not harmed, if rid by the time the Midsummer-shoots spring up, but they had not rid this year, 1697, by the latter end of July.

"It is observed, that coppice wood, cut for hedging at the latter end of winter, will not endure so long by a year as that which is cut at the beginning of winter; which, as I believe, may not only be, because the wood late cut, is cut after the sap has risen, or attenuated by the sun, but also oftentimes because it is not cut long enough before such rarefaction is made; for, if a tree, or a cyon cut to be grafted, as Quinteney affirms, will endure many weeks of the winter out of the ground, or without being grafted, and, when spring shall come, it will by virtue of the sap inherit in it, when attenuated put forth buds for some time, till it dries away; so it follows, that the sap inherent always in the stem of the wood, if not cut so early as to have long time to dry, may be put into motion at spring, so as to effect the abovementioned inconvenience; therefore I hold hedging-wood and fire-faggots should be cut in October.

"It is a common practice of husbandmen to fell their hedge-rows, and small brakes within the grounds, those years they sow the grounds with wheat; but such persons ought well to consider, first, whether such land, after the wheat is off, will not bear a rowet too long for sheep to eat, and, if so, great cattle must be put in to eat up the long rowet, and the sooner the better for their tooth; and then attendance must be given by a cow-keeper by day, before the harvest is in, and consequently the wages dearer, and when you may have many other offices to employ such a person in: therefore, in such case, my advice is to let the hedge rows stand till after the wheat crop be got in, when great cattle may be suffered to feed down the rowet without prejudice to the hedge-rows, and at that time of the

year such grafs is wanted by night ; and during the future three crops, it is to be supposed the rowet will not be so large, but sheep may overcome it, nor will they very much prejudice the young wood." *Lisle's Husbandry, vol. II. p. 245.*

In raising coppices, great care ought to be taken that the wood they are to be composed of be such as is proper for the soil you raise them on, and that it be proper for the uses you design to sell it for, which you must be regulated in by the vent you have ; and let the profits resulting from your under-wood regulate the thickness of your standards ; for in proportion as they are thicker or thinner, they will do more or less injury to your under-wood. You should likewise consider at what growth you can sell your under-wood ; only remember that the older and taller your under-wood is, the better it is both for fuel and for what standards you leave, because they will be taller and straiter, by being forced up by the wood that grows about them ; though a deep soil contributes much to their springing. It is also necessary, about the time of your felling, to lay out your several falls, that you may have an annual succession, to yield a yearly profit. But though the seldom felling of coppices yields the more and better wood ; yet the frequent cutting of it makes it thicken, and gives room for the seedlings to come up. If many trees grow in the coppice that is to be cut down, fell both them and the under-wood together, cutting off the stubs as near the ground as convenient, and those of the under-wood a-slope and smooth, and not above half a foot from the ground ; and stock up the roots of the timber-trees, if they send forth no shoots, in order to make room for seedlings and young roots to grow.

The under-wood may be cut from the beginning of October to the latter end of February ; but February is the best month to cut wood in, where you have but a small quantity to fell, that you may do it before the spring comes on too much : take great care to prevent the car- ters from brushing against the young standards, and let all your wood be carried out by Midsummer, and made up by the end of April at the farthest ; for if the rows and brush lie longer unbound or unmade up, it will spoil many of the young shoots and seedlings. If the winter before you fell, you enclose it so as to keep all cattle out of it, your care and trouble will be well recompensed.

Your elder under-wood may be grazed about July, or in winter ; but, for a general rule, newly weaned calves are the least prejudicial to new cut wood, where there is abundance of grafs ; and some say colts of a year old ; but then they must be drove out by the beginning of May at farthest. However, if nothing at all be suffered to come in, it will be better. In this every man's experience must direct him.

If your woods happen to be cropt by cattle, it will be better to cut them down, and they will then make fresh shoots ; whereas what has been bit by the cattle, will be otherwise stunted for several years before it will take to its growth. *Mortimer's Husbandry, vol. II. p. 69.*

CORD of Wood, a certain quantity of wood for fuel, properly stacked up ; so called because it was formerly measured with a cord. The dimensions of a statute cord of wood are eight feet long, four feet high, and four feet broad.

CORE, a disorder incident to sheep, occasioned by worms in their liver, resembling a plaice, or flounder.

A sheep, if chiefly feed with hay, will live a year after being affected with this distemper, by which time he will

have a water-bladder as large as an egg, under his throat ; at the same time his eyes, mouth, and gums, will be white.

If any sheep in a flock core during the winter, it will be easily seen at shearing-time ; for such sheep will be poorer than the rest ; their wool also will run into threads, twisting together at the ends, and look somewhat like teats. The last particular is not however a certain sign of a sheep's being cored ; for sometimes the wool of very sound sheep will be apt to run together into threads ; and the finer the wool the more apt it is to twist together in that manner. There is no method of curing this distemper hitherto known. *Lisle's Husbandry, vol. II. p. 207.*

CORIANDER, the name of a plant formerly much cultivated in England ; but at present little of it is sown.

The seeds should be sowed in autumn on rich land ; and when the plants are come up, they should be hoed out to about four inches distance, every way, clearing them from weeds. By the above management, the plants will grow strong, and produce a greater quantity of good seed. *Miller's Gard. Dict.*

CORN, a general name for grain that grows in ears, not in pods, as wheat, barley, &c.

If corn be lodged, it may be cut before it is quite ripe ; and if blighted, it cannot be cut too soon. But if neither of these accidents happen, both wheat and barley should be suffered to stand till full ripe. The grain will also grow plumper by being left a while in the field after cutting, to take the dew ; but the straw will be injured by it ; nor must it by any means be laid up damp in the mow, lest it heat, and become what is called mow-burnt ; and perhaps take fire. A great number of weeds will produce the same effect, if the corn be housed before their stalks are sufficiently withered.

A correspondent of the authors of the *Museum Rusticum* tells us, that in the year 1763, he had twenty acres of barley, which was rather weedy at harvest ; on which account he was desirous of giving it as much field room as he could conveniently ; but the weather promising to be very wet, he was obliged to cart his barley, which he put into the bay of a large barn.

Whilst this work was going forward, he was called away, and in his absence his son got a horse upon the mow to tread it ; by which means, the weeds, not being thoroughly dry, caused the barley to heat to so violent a degree that he was very apprehensive of its firing.

" My men, adds he, were in a violent hurry to get it out of the barn ; but this I would by no means consent to. I however ordered one of them to get upon the mow with a cutting knife, and cut in it a round hole like a well. He began the work ; but in about five minutes, being almost overcome by the heat, I sent another to relieve him ; and thus they worked spell and spell, till they got to the bottom.

" This round hole saved my barley, and perhaps my barn too ; for it formed as it were, a chimney or flue to carry off the heat." *Museum Rusticum, vol. III. p. 365.*

For the method of preserving corn after it is threshed, see the article **GRANARY**. And for preserving it in the straw, see **REEK**.

Mr. Young, in the fourth volume of his *Annals*, gives the general average price of corn for fourteen years and his observations on the subject.

In the years 1772, 1773, and 1774, the complaints which resounded through the kingdom upon the high price of corn, are in every one's recollection: committees of the house of commons sat repeatedly to enquire into the cause, and the press swarmed with publications, the authors of which attributed the high prices by turns to almost every circumstance of the internal policy and state of the kingdom. No use would result for mentioning the trifling and inadequate causes to which the effect was referred; the circumstances which a few authors of note pitched upon were, large farms, and inclosures, the increasing predominacy of which were considered as great evils, and particularly bearing upon the point in question.

Endeavours were made to refute those ideas, and to prove, that ten years of peace, in which every branch of national industry had been carried to an uncommon height, having introduced a flood of wealth, were amply sufficient to account for the high price, not of corn only, but of every commodity in the nation, the rate of which could be affected by the quantity of circulating specie.

The table which we insert yields as strong a confirmation of the former reasoning as the power of events could give. Large farms have continued to the present moment, and inclosures gone on as rapidly as ever, yet we see the prices of every sort of corn sinking in 1779 and 1780, as low as they had been high before. And it is fresh in every one's recollection, that all the products of the earth were almost equally low, and the farmers in a more melancholy situation than they had been in for half a century before. Such a contrast of prices in so short a period cut up by the roots, and did away for ever all the arguments that had attributed the high prices to great farms or inclosures, or the conversion of arable to grass, or to any of the numerous causes that have been so anxiously sought for. But we may observe, that this was not the case with the cause to which had been attributed those high prices, viz. to circulating wealth from national prosperity: for no sooner had the American war come into full operation, and had diffused throughout the kingdom its baneful influences; such as an impeded and languid circulation; a reduced consumption; a comparative stagnation in trade and manufactures; with a consequent poverty in all ranks of people, but the prices of corn and other commodities sunk proportionably, without having a shadow of reference to the size of farms, or number of inclosures. But farther; the experiment became double, for after that point of depression suffered by the national industry in consequence of the war, fixed at 1779; the prices arose with the returning prosperity of the kingdom, until they got up to their full standards, and perhaps above it. This great variation of prices, in so short a period as twelve years, ought, by every unprejudiced man, to be received as a double proof, first, that the size of farms and inclosures have had nothing at all to do in the question; and, second, that the cause must be looked for alone in the prosperity, wealth, circulation, and consumption of the kingdom.

It is true, there are many persons who incline to think that the principal variations in price are owing to the difference of seasons; some years being very favourable to the growth of corn, and others much the contrary; and we find annexed to Mr. Whitbread's manuscript, some remarks on the season for each of these twelve years, an abstract of which is here given:

- 1771, Preceded by a severe winter.
- 1772, A very wet harvest.
- 1773, Great rains and floods in May.
- 1774, A wet harvest.
- 1775, A very dry time from March to Midsummer.
- 1776, A severe frost from January 7th, to February 1st, with an unusual fall of snow; fine season following.
- 1777, August and September the finest ever remembered, and the whole season generally good.
- 1778, The summer remarkably dry, and a fine harvest.
- 1779, A general good season.
- 1780, Cold and wet winter, backward spring, and dry summer.
- 1781, Winter open and dry; a growing summer; mild.
- N. B. The three last years dry upon the whole, and corn plentiful.
- 1782, The wettest, coldest, and backwardest spring ever known; great floods; wet and cold summer, with floods in August; mildew, and very little corn ripened or got in well. The greatest crop of grass ever remembered, but the hay spoiled.

1783, Winter favourable, spring fine, and the summer hot and burning.

1784, The last week in December, a frost set in, which lasted with snow till the 21st of February. In March deep snows and frosts; and the backwardest spring ever known; wet harvest.

Many circumstances could be added to this detail if essential. In Suffolk the mildew, in the years 1780, 1781, and 1782, destroyed and damaged more wheat than any other distemper has done in half a century. 1783, was free from it. 1784 has it, but in a much less degree. The phlogisticated state of the atmosphere in 1783, from which foreign philosophers deduced immense crops, passed away without producing them. There are three seasons critical with wheat: in winter frosts, too much wet and severe cutting winds kill it; this is to be totally avoided by sowing early in September. In the spring, when the first set of roots die, and are succeeded by a second system of fibres, at which period the blade turns yellow; then hand-hoeing and top-dressing takes effect. The last is at flowering-time; refreshing moderate rains just when it is beginning, and fine, dry, warm weather while it lasts, are conducive to a great crop: as to the harvest, it shares the fate of all other crops, the better the weather, the better got. But at this season rains have not half the ill effect of wheat properly shocked as on that in the common method. Three sheaves beneath, and one longer above, and bound nearer the butt, inverted over the others.

We are strongly inclined to think that though the season has a most powerful influence upon any given field, farm, soil, or district, so as to make the difference of a great crop or a very poor one; yet when we consider the kingdom at large, I believe the influence is not great. In very northerly climates, where a harvest is sometimes utterly lost, this reasoning would not hold good; but that is never the case in England. We are to remember, that the wet years which damage the clay lands, make the fortune of sand farmers, and we are also to have in mind, that the improvements of draining and laying the land round and dry, which it is to be hoped spread daily through the kingdom, are constantly lessening the greatest evils of wet soils; we are also to recollect, that though dry years, in general, suit clay countries, yet there must at certain seasons be a great deal of rain to enable the farmer to cultivate them at all; clays, for every thing but wheat, have been observed to bear a drought worse even than some sandy soils. Thus it is not very easy to describe or point out the season that shall be attended with the greatest crop in England. But there is another consideration which seems to throw the matter of season much more out of the question than these observations, and that is, not the prices of corn only, but of all other products. If bad seasons occasioned the high prices of corn in 1772, 3, 4, why did those seasons make every sort of cattle as dear as corn? the dearness ran through every article that can be named. On the contrary, if good seasons in 1779 and 1780 (and by good is generally understood dry) brought down corn to a price that starved the farmers; how came all sorts of cattle, fat and lean, to be at as depressed a rate as corn? A dry season can work no such effects as lowering prices of oxen and sheep cent. per cent. Again, for as we before observed, the experiment is double, when bad seasons returning in 1782 and 1783, (though, by the way, 1783 was one of the driest years that have been known in England for a century, and consequently ought to have been attended according to the reasoning we combat with a low price) how come cattle, fat and lean of every sort and kind, and all the products of the earth in general, to rise with corn in the manner we have seen, and at this moment experience? To say that a scarcity of bread creates a greater consumption of other food, is giving no satisfactory reply. The fact is true with but a very few commodities: wheat being excessively dear, will drive the poor to barley, or rye bread, or to potatoes; but not to beef or mutton, much less to horses or lean sheep: and the high price of malt may drive them to gin, possibly to water, but it will not make them the greater consumers of lean pigs.

The circumstance, therefore, which influences these prices, must be sought for, not in seasons whose effects would necessarily be local and partial, but in some more general cause that operates equally over the whole kingdom; this cause we find in the wealth and circulation of the people. It agrees with political data that enables us to reason upon it; the vibrations are correspondent; and those effects, which we have experienced, ought to flow from the causes that

that are open to every eye, and the events that have happened in every one's recollection.

The price upon the general average of 5s. 6d. a bushel for wheat during these 12 years, is something above what would have paid the farmers well 20 years ago, when 5s. was a fair price, and sufficient to give encouragement. We are inclined to think, and I trust, without any undue predilection for the farmer, that the price ought now to be 6s. which we do not think, upon the whole, better for him at present than 5s. was twenty years ago; owing to the rise of poor rates.

The average price of wheat in France, during these twelve years, was from 24 to 25 livres the *sceptier* of 240 lb. but as the mean weight of a Winchester bushel of wheat in England does not amount to 60, we may deduct one tenth upon the account, and then the French price reduced to English, will be 4s. 10½d. per bushel. The price in France, August 1784, was 27½ livres, or 5s. 5¼d. per bushel. The London price in that month was 5s. 10d.

The London prices during this period have been,

Years.	Wheat.	Rye.	Barley.	Oats.	Beans.
1771,	5 4	4 0	3 0	2 2	3 2
1772,	6 3	4 3	3 1	2 1	3 5
1773,	6 4	3 7	3 3	2 2	3 6
1774,	5 11	3 2	3 2	2 2	3 4
1775,	5 8	3 3	3 0	2 0	3 2
1776,	4 7	3 0	2 4	2 0	3 1
1777,	5 5	2 11	2 5	1 11	3 4
1778,	4 11	2 10	2 7	1 11	3 0
1779,	4 2	2 5	2 5	1 10	2 5
1780,	4 7	2 3	2 2	1 9	2 3
1781,	5 6	2 8	2 0	1 9	2 5
1782,	5 9	2 9	2 7	2 1	2 9
Average	5 4½	3 1	2 8	1 11½	2 11½

If we compare these prices with the general averages of the whole kingdom, we shall see a remarkable fact that they are lowest where the demand is greatest. This is the case with wheat, rye, barley, and beans. Oats are an exception, owing, doubtless, to the capital being supplied more from abroad with that grain than any other. This cheapness, where there is a great demand, is perfectly consistent with the principles of commerce, and ought to be a strong conviction on the mind of those ministers and statesmen in other countries, who lay restrictions on the corn trade, fearing the want of so necessary a commodity: they should from hence be convinced, that a great demand is the surest means, while trade is free, of securing a supply; and that they have nothing to do but to give permanency to freedom, in order to ensure a perpetual supply. Much, however, in this case depends on London being a sea port, for inland countries cannot receive their corn from a distance, without charges that add greatly to its price. Powerful as the principle is, it cannot overcome such circumstances as the seat of manufactures being in a country of mines and pasturage, which is the case of several of our western counties. To draw out many of these comparisons in tables would be tedious, but if the reader compares the prices of Norfolk, Suffolk, Essex, Kent, and Sussex; with Derby, Lancaster, Worcester, Westmoreland, Monmouth, Somerset, and Devon, he will find that the contrast is very considerable. In fact, many of the western counties receive their corn at all times from Lynn, Yarmouth, and other ports on the eastern coast, which must necessarily add to the price, when there is not only a long sea voyage, but a transport also on canals or rivers.

We may also observe, upon the London prices compared with those of the kingdom at large, that they are more equal. The variation between the highest and the lowest is less; and those both exceed the medium in a less degree. This greater steadiness of one city over a whole kingdom is remarkable, for it might be thought, that the overplus of some markets answering the deficiencies of others, might on the average of so many, induce a more exact level; but the contrary is the case, and owing to the operations of demand meeting an unobstructed supply.

As a contrast of price, let us insert those of Lancaster and Sussex.

Years.	Lancaster.	Sussex.
1771,	— 6 5	— 5 0
1772,	— 6 9	— 5 10

Years.	Lancaster.	Sussex.
1773,	— 6 8	— 6 1
1774,	— 6 10	— 5 9
1775,	— 6 1	— 5 7
1776,	— 5 6	— 4 5
1777,	— 5 11	— 5 2
1778,	— 5 11	— 4 7
1779,	— 5 1	— 3 9
1780,	— 5 1	— 4 5
1781,	— 5 9	— 5 8
1782,	— 6 4	— 5 9
Average,	— 6 0½	— 5 2

This is the greatest contrast in the whole kingdom.

The quarterly prices of the twelve years, being reduced to average, will be as under.

	Wheat.	Rye.	Barley.	Oats.	Beans.
From Christmas to Lady-Day,	5 5½	3 6½	2 9½	1 10	3 4½
From Lady-Day to Midsummer,	5 7½	3 9½	2 10	1 11½	3 5
From Midsum. to Michael,	5 9½	3 9½	2 10½	2 0½	2 5½
From Michael to Christmas.	5 5½	3 7½	2 10	2 5	3 5½

Some of the most important circumstances that can direct the conduct of a farmer, are to be deducted from this little table. It shews how exceedingly erroneous it is in any man to thresh his corn at unseasonable times with a view to a better price. Nothing more common than to see half fed cattle, and crops half starved for want of dung, while a great portion of the straw of a farm is almost lost by being threshed when the cattle cannot eat it. Nothing can be clearer than the mistake of such a conduct. Here is a gradual and regular rise during three quarters of the year; but it is by no means answerable to any inconvenience in point of consuming the straw. By keeping his wheat till after Midsummer, a farmer gains only 3½d. a bushel upon an average of 12 years. The difference of a summer and winter price of threshing deducted from this, what is there remaining to make amends for the almost total loss of the straw? It may be answered, that the farmer sells his straw: so much the worse; for the near neighbourhood of great cities alone excepted, that is an execrable losing custom, which tends only to impoverish a farm, and if keeping corn till the cattle will not eat the straw is done on that account, two mischiefs arise instead of one, but never will apologize for each other. But another consideration, and a most powerful one, is the damage done by vermin: rats and mice in many situations devour quantities of corn; but very small depredations indeed will be sufficient totally to wipe out this trifling rise of price.

The difference of price some years is certainly much higher than appears in this table. Thus in 1777 the difference in half a year in the price of wheat was 1s. 1d. a bushel. In 1774 it was 10d. and 6d. in 1773, and in such years the difference is still higher if only the finest corn in the market is attended to; such years tempt farmers to listen to accounts which, though true in themselves, are utterly false as an argument for speculating: nor do they take into the account other years in which prices fall instead of rise: thus in 1781 wheat fell 4d. from Christmas to Midsummer. It fell in 1779. In 1778, 7d. and 9d. in 1775; indeed conversation rarely turns on this subject without many instances occurring of farmers that have lost instead of gaining by their speculation.

Hence, therefore, we may very safely advise every farmer to reject all speculation, as sure in the long run to prove a loss; but to thresh and sell his corn all within the season of feeding his cattle with the straw. He will gain more in their well-doing, and in avoiding the depredation of vermin, than he can ever justly expect to gain by the rise of markets.

CORN-CROWFOOT, a weed very common among the corn. It has an upright stalk; the leaves are of a pale green, and cut into long, narrow, acute segments. The flowers are much smaller and paler than the crowfoot of the pastures: but the seed-vessels are the most remarkable, being covered all over with prickles. See Plate V. fig. 33.

CORN-

The figures from 1 to 31, Inclusive, are explained in the Article Butterfly.

CORN-FLAG, a very troublesome weed, multiplying exceedingly by its roots. It has a round compressed tuberos root, which is of a yellowish colour, and covered with a brown furrowed skin, like that of the vernal crocus. From this root arises two flat sword-shaped leaves, which embrace each other at their base; and between these arises the flower-stalk, which grows near two feet high, having one or two narrow leaves, embracing it like a sheath. This stalk is terminated by five or six purple flowers, standing above each other at some distance, and ranged on one side of the stalk; each of these has a sheath, which covers the flower-bud, before it expands, but splits open lengthways when the flowers blow, and afterwards shrivels up to a dry skin, which remains about the seed-vessel, till the seeds are ripe, which is in the beginning of August. The flowers come out in the beginning of May, or in June. Some of these flowers are white, and others flesh-coloured.

Corn-flag is extremely difficult to root out, as every part of the root will grow. The best manner of extirpating it is that already mentioned under the article colts-foot. See **COLTS-FOOT**.

CORN-MARYGOLD, the name of a very troublesome weed, of which there are two species, one common in corn-fields, and the other in moist pastures. The leaves of the first sort embrace the stalks, the upper being jagged, and the lower indented like a saw. The second is, by C. Bauhine, called the greater wild daisy, with a leafy stalk. It rises with stalks near two feet high, furnished with oblong indented leaves, which embrace the stalks with their base. Each of these stalks is terminated by one white flower, shaped like that of the daisy, but four times as large. It flowers in June. See Plate V. fig. 34.

The corn-marygold has a perennial woody root, which striking deep requires a considerable quantity of food, and therefore must be a great enemy to the corn. Considerable pains must be taken before this weed can be extirpated, as it is highly probable, that, besides multiplying by its roots, its seed will grow, if ploughed in, as that of the garden marygold will do when dug in. Deep and repeated hoeings are therefore necessary, before it runs to seed.

CORN-PARSLEY, the name of a low branching plant common among corn. The branches grow thick together, and are knotted and crooked. The flowers grow close together after the manner of parsley, and are of a white colour inclining to yellow. The seeds are large in proportion to the plant; and are set about with little crooked bristles, which makes them adhere to the stockings in great plenty, when the seeds are ripe, which is generally about harvest. See Plate V. fig. 35.

CORN-WORM, the insect lately observed in France to be so very destructive to corn. See the article **BUTTER-FLY**.

CORNER-TEETH, are the teeth which appear when a horse is coming five years old. See the article **AGE**.

CORONET, the lowest part of a horse's pastern, which runs round the coffin, and is distinguished by the hair which joins and covers the upper part of the hoof.

COSH, the same with pods. See the article **POD**.

COSSART, or *Coffet Lamb*, a lamb left by its dam's dying before it is capable of shifting for itself; or it is a lamb taken from an ewe that brings two, three, or four lambs at a yeanning, and consequently is incapable of bringing them all up. The word is also applied to a colt, calf, &c.

In either of these cases, if there be not another ewe at liberty to suckle it, it must be brought up by the hand, or perith. By an ewe at liberty is meant, one that has, by some accident, lost her lamb, and has milk enough to suckle a lamb yeanned by another.

COSTIVENESS, a complaint to which horses are often subject; sometimes occasioned by violent and hard exercise, especially in hot weather; and sometimes by standing long at hard meat, without grass, or other cleansing diet, and with very little exercise.

The cure for this complaint is easy, only by giving him an open diet for some time; and if any thing more is wanting, lenitive mild purges are the most likely to succeed. Such as Glauber's salts with lenitive electuary, four ounces of each, dissolved in warm ale or water, and repeated every other day. This, with scalded bran given every day, will soon remove the complaint, and carry off the viscid slime engendered in the guts, which is generally the cause of his costiveness.

But there is another kind of costiveness in horses, which

is much harder to be removed, viz: that which seems to be natural, or grown into a habit. We find some very good horses liable to this disorder; and, when it is of long continuance, they are apt to grow lean and emaciated; feel hot and dry, their hair staring, and there is danger of some approaching sickness.

This disorder is not easily removed, nor is it often necessary to bring such horses into a contrary habit; for where this is natural, it may proceed from a more than ordinary strength and rigidity in the small fibres of the stomach and guts, which makes them digest their aliment well, and retain their excrements longer, and when such a habit can be kept within any proper medium, the horse will continue in strength and vigour, without any inconvenience; and it is observable, that these horses are, for the most part, able to endure great fatigue and labour. However, it is proper to give such horses, at all convenient times, an opening diet. For if this habit happens, by any accident, to grow into an habitual costiveness, so as to produce ill effects, as heat; dryness of the constitution, little scabby eruptions over the skin, and a rough coat; it will then be necessary to remove it in some degree, which cannot be done but by a continual use of emollients, joined by a loose opening diet.

Purging is here also necessary, and ought by all means to be complied with; but purging in the common way with Barbadoes or other plantation aloes, seldom has any great effect longer than the purge is working; for when that is over, the same habit of costiveness generally returns as strong as ever. Scalded bran, and the common opening diet, seldom makes any great alteration in these horses. The aloetic purges will scarcely work, especially if they are made strong, for they then chiefly run off by urine, which does the creature little service in this case. But after the common purges have failed, the following will succeed beyond expectation.

Take succotrine aloes, six drams; spermiaceti, half an ounce; fenugreek-seeds in powder, two ounces; make the whole into two balls, with a sufficient quantity of honey, or common treacle, and give them in a morning fasting.

Let the horse have scalded barley instead of scalded bran, and the liquor of the barley for his drink, milk warm. This will work very gently; where stronger purges have little other effect upon costive horses than to gripe and make them sick. It ought to be repeated once in four days, and may be continued till he has taken six doses. Let him have an ounce of fenugreek-seeds once a day, in one of his mashes, and when the purgation is over, continue the use of the fenugreek; and sometimes give linseed in the same manner, either in his dry or moist feeds, until the horse grows smooth and well coated, and his dung moist and in good order. *Gibson's Farriery, vol. II. p. 134.*

COTYLEDONS, rinds, or husks.

COUCH-GRASS, *quick-grass, knot-grass, or dog-grass*, is one of the worst of weeds among corn, and one of the most difficult to extirpate in arable land; every joint of its long creeping roots being capable of soon producing a new plant, after those roots have been broken by the plough. The usual way of destroying it, is by laying the land fallow in summer, and frequently harrowing it well over, to draw out the roots, every piece of which should then be burnt, for the reason already mentioned. Where this is carefully done, the ground may be so well cleansed in one summer, that the remaining roots will not do any great injury to the ensuing crop: but the best way is to sow the land in which this weed prevails with such plants as require the horse-hoeing culture. The blade of this grass is so rough, that the cattle will not feed upon it when green.

Mr. Young, in his *Annals of Agriculture*, recommends trench-ploughing as a proper method to destroy couch-grass; where he says one earth given deeply with his skim-plough, and after that a hoeing system on the surface, will convert the couch to a manure.

COUVERT, sheltered, not open, not exposed.

COUGH, a convulsive motion of the lungs, being an effort of nature to throw up some offending matter.

Horses are very subject to coughs, which are sometimes occasioned by colds, and often by the injudicious treatment of an inflammation of the lungs; the consequence of which is often settled habitual coughs, which frequently degenerate into asthmas, and broken wind.

Nothing has more perplexed practitioners than the cure

of settled coughs; the cause of which, perhaps, has been their want of attention to the different symptoms which distinguish one cough from another; for without strict observance thereof, it is impossible to find out the true method of cure.

Thus, if a horse's cough is of long standing, attended with a loss of appetite, wasting of flesh, and weakness, it denotes a consumption; and that the lungs are full of knots, hard substances, called tubercles, which have often been discovered on dissection.

The following signs denote when the cough proceeds from phlegm, and slimy matter, that stuff up the vessels of the lungs.

The horse's flanks have a sudden quick motion; he breathes thick, but not with his nostrils open, like a horse in a fever, or that is broken winded; his cough is sometimes dry and husky, sometimes moist, before which he wheezes, rattles in the throat, and sometimes throws out of his nose and mouth great lumps of white phlegm, especially after drinking, or when he begins or ends his exercise, which discharge commonly gives great relief. Some such horses wheeze and rattle to such a degree, and are so thick winded, that they can scarce move on, till they have been out some time in the air; though then they will perform beyond expectation.

These are properly asthmatic cases, and ought to be distinguished in their symptoms from that puriveness and thick windedness we see in some horses, occasioned by too full, or foul feeding, want of due exercise, or their being taken up from winter's grass. But these two last cases are easily cured by proper diet and exercise; the one by lowering his keeping, and the other by increasing it.

The above asthmatic case proves often very obstinate; but, if it happens to a young horse, and the cough is not of long standing, it is greatly relieved, if not totally cured, by the following method.

If the horse is full of flesh, bleed him plentifully; if low in flesh, more sparingly; which may occasionally be repeated, on very great oppressions, and difficulty of breathing, in proportionate quantities.

As mercurial medicines are found remarkably useful in these cases, give a mercurial ball, with two drams of calomel, over night, and a common purge the next morning; or the following, which is much recommended by Mr. Gibson:

Take gum-galbanum, ammoniacum, and assa-fœtida, of each two drams; fine aloes, one ounce; saffron, one dram; oil of aniseeds, two drams; oil of amber, one dram; with honey enough to form into a ball.

They may be repeated at proper intervals, with the usual cautions. In the intermediate days, and for some time after, one of the following balls may be given every morning:

Take cinnabar of antimony, finely levigated, six ounces; gum-ammoniacum, galbanum, and assa-fœtida, of each two ounces; garlic, four ounces; saffron, half an ounce: make into a paste for balls, with a proper quantity of honey.

These balls are extremely well calculated for this purpose: but if they are thought too expensive, the cordial ball may be given, with an eighth part of powdered squills and Barbadoes tar: or equal quantities of the above, and the cordial ball, may be beat up together; and where they can be afforded, balsam of Peru, balsam of sulphur, and flower of Benjamin, would undoubtedly, added to the cordial ball, make it a more efficacious medicine, in cases of this sort, as thus:

Take of the pectoral or cordial ball, one pound: balsam of Peru, half an ounce; balsam of sulphur anisated, one ounce; flower of Benjamin, half an ounce; honey as much as is sufficient to form them into a paste: give the size of a pigeon's egg every morning.

Exercise in a free open air is very serviceable, and the diet should be moderate. Horses subject to any inward oppressions of the lungs, should never be suffered to have a belly full; that is, they should never be permitted to distend their stomach with meat or water, as to press against the midriff, which of course would hinder respiration. Their hay should even be abridged, given in small quantities, and sprinkled with water; and their usual allowance, both of corn and water, should be divided into several portions: by such a regulation in diet, horses may be so recovered as to do great service; and in all disorders of the lungs, it is what should principally be attended to.

The following are the symptoms of a dry cough, or asthma.

The horse afflicted with this cough, eats heartily, hunts, and goes through his business with alacrity, appears well coated, and has all the signs of perfect health; yet he shall cough at particular times almost incessantly, without throwing up any thing, except that the violence of the cough will cause a little clear water to distil from his nose. Though this cough is not periodical, yet some of these horses cough most in a morning, after drinking.

This may properly be styled a nervous asthma in a horse, as probably it chiefly affects the nerves in the membranous parts of the lungs and midriff; and is a case very doubtful at least, if not incurable: but when the horse is young, the following method may be successful.

Take away first a moderate quantity of blood; then give him two drams of calomel, mixed up with an ounce of diapente, for two nights; and the next morning a purging ball. Keep him well clothed and littered, and feed him with scalded bran and warm water.

Once in eight or ten days this purge may be repeated, with one mercurial ball only given over night.

The following balls may then be taken, one every day; about the size of a pullet's egg, the horse fasting two hours afterwards; and should be continued two months, or longer, to be of real service.

Take native cinnabar, of cinnabar of antimony, half a pound; gum-guaiacum, four ounces; myrrh, and gum-ammoniacum, of each two ounces; Venice soap, half a pound: the cinnabar must be finely levigated, as before observed, and the whole mixed up with honey, or oxymel squills.

The following also will be found a useful remedy in obstinate dry coughs:

Take gum-ammoniacum, squills, and Venice soap, of each four ounces; balsam of sulphur, with aniseeds, one ounce; beat up into a mass, and give as the former.

These mercurial and ponderous medicines are well adapted to open obstructions in the lungs, and prevent those little knots, or tubercles, which so frequently ulcerate, and lay the foundation of an incurable malady, or consumption; but the common pectorals alone will avail nothing in old stubborn coughs, their efficacy being lost in the long tour they have to make, before they come to the lungs; and indeed, were it otherwise, without they had such powerful openers joined with them, they would be of little consequence; for where there are expectations from medicines, such are chiefly to be relied on which have a power of dissolving and attenuating the viscid humours, opening the small obstructed vessels, and promoting all the natural secretions.

Before we conclude this article, it may be necessary to observe here, that some young horses are subject to coughs on cutting their teeth, their eyes are also affected from the same cause. In these cases always bleed, and if the cough is obstinate, repeat it, and give warm mashes; which, in general, are alone sufficient to remove this complaint. But when the cough is an attendant on worms, as it often is in young horses, you must give such medicines as have a power to destroy those animals: particularly mercurial physic, at proper intervals, and immediately half an ounce of Æthiop's mineral, mixed up with the cordial; or pectoral balls may be given every day. See WORMS. Bartlett's Farriery, p. 51.

But horses are not the only animals subject to this disorder: it is so common among sheep, that one seldom passes near a flock without hearing it in several. They cure this disorder in the Ardennes by throwing up their nostrils with a syringe blanchéd almonds pounded in wine, for six or eight days successively.

COUPLES, ewes and lambs.

COW, the female of the bull.

Cows are very serviceable to the husbandmen for work, and for the supply of the family and market. The best breed is reckoned that of Yorkshire, Derbyshire, Lancashire, Staffordshire, &c. and a good hardy sort for fattening on barren, or middling sort of land, are your Anglesea's and Welsh. The hardiest are the Scotch; but the best sort of cows for the pail, only they are tender and require very good keeping, are the long-legged, short-horned cow, of the Dutch breed, which is to be had in some places of Lincolnshire, but mostly in Kent; many of these cows will

will give two gallons of milk at a meal: but in furnishing yourself with cattle, you ought to consider the goodness of your land, and the use you design your cattle for, as whether for breed, milk, or work.

If for breed, the better your land is, the larger may your kind be; and the cheaper, the more will be your profit: only observe, that of what kind soever your breed is, that it be the best of the sort; and let your bull be of the same country with your cow, for a mixed breed is not reckoned to be so good.

The cow ought to have a broad forehead, black eyes, large clean horns, her neck long and thin, a large deep belly, thick thighs, round legs, short joints, a white large deep udder, having four teats, and her feet large. In the winter management of dairy cows, one circumstance may be noted: that of their being frequently kept (in conformity to a modern practice adopted by some leading men) in sheds, continually throughout winter, from the time of their being taken up in autumn, to that of their being turned to graze in the spring; generally four months, without any exercise.

Some discerning individuals, however, have already discovered the inconveniences of this practice, especially that of their hoofs cracking, let them loose in a yard, a few hours every day, to moisten their feet, as well as to exercise their legs, and clean their coats.

Though a dairyman may in general rear his own cows, he must be fortunate indeed if he never have occasion to purchase a cow.

Mr. Marshall, in his *Rural Economy of Gloucestershire*, says as follows: The favourite points of a milking-cow here are, a thin thigh; a lank thin-skinned bag hanging backward; teats long, and sufficiently free of milk without spilling it; dug veins large; and horns yellow. I will not vouch for the infallibility of all these points; but this I can say, that I never noticed a cow with a thick fleshy thigh which was a good milker.

The dimensions of the handfomest cow I have seen of the true Vale breed, rising five years old, and within a few months of calving, are as follow:

Height at the withers, four feet, five inches.

—— of the brisket, eighteen and a half inches.

Smallest girt, seven feet one inch.

Largest girt, nine feet two inches.

Width at the shoulder, twenty-one and a half inches.

—— huckle, twenty-four inches.

—— round-bone, nineteen inches.

Length from forehead to nache, seven feet five inches.

—— center of the shoulder-knob to center of the huckle, three feet eleven inches.

—— center of huckle to the out of the nache, twenty-one inches.

Length of the horns, ten inches.

Width at the points, eighteen and a half inches.

Head, neck, and leg, fine and clean.

Chine full, and back level.

Colour, a darkish red mottled with white.

There is a disadvantage common to all the varieties of the short horned breed. This is their difficulty in calving. For notwithstanding the fleshiness of the hind-quarter has been sufficiently done away, the bones still remain. The loin is still broad, and the huckles still protuberate; perhaps too much, either for lightness or use.

An improper treatment of the cow may encrease the difficulty. A cow can scarcely be too low in flesh a month before she calves. Good keep three weeks or a month before calving gives due strength and a flush of milk. The cause may be difficult to point out with precision; but the effect is well ascertained.

It is a fact, that short-horned cows seldom calve without assistance. Their hour of calving is watched with obstetric solicitude; the person who has the care of them frequently rising in the night, and sometimes sitting up with them the night through. From constant observation, however, a good dairyman will judge at bed-time the hour of calving, sufficiently near to know whether it will be necessary for him to rise before his usual time.

Mr. Young, in his *Annals of Agriculture*, vol. xii. gives, from a letter of Mr. Macro, the following experiment, wherein he says, "I have just seen, on looking over my last year's pocket book, an account of two experiments I made last summer, on milking a cow from two to four times in a day, which I do not remember to have given you, and which are as under.

May 21st, 1789.			October 22d, 1789.

		26			16

Mr. Young, in the thirteenth volume of his useful work, gives a letter from Mr. John Foote of Brandon in Suffolk, who says, "In the year 1782, I had an experiment tried on a cow about ten years old, that had had six or seven calves; found she was going off profit; had not taken the bull: had her spayed in the spring; kept her two or three weeks from the cold, soon after she began to thrive and do well,—by the latter end of summer was near fat; had she gone in good pasture would probably have been quite so. She improved apace and paid well; was worth about 25s. when cut; and sold most of her at 3s. 6d. a stone, her weight 25 stone. The spaying of cows may be of service if properly attended to, such cows as grow less profitable to the pail, may answer well for grazing: the spaying them affords time, and renders them safe from calves, which otherwise they would not be, where any bull is kept near them. There appears little hazard in having it done by a skilful hand; the parts taken away are only the ends called the luffs; when done throw in a handful of salt, and stitch up the wound with a double wax thread.

"In January 1787, I had a cow spayed, about fourteen years old, after calving about a month, having had a large calf which was forced to be drawn from her by four men; that she was very weak, yet did very well; in a week's time seemed little affected by being cut; and afterwards another. These cows after spaying, milked a considerable time longer than usual; improved apace and fattened well. A cow of five or six years old, that does not answer to milk would improve to graze by being spayed. Some other farmers in the neighbourhood have experienced the same."

As for the size of your cows, as of all other cattle, it must be suited to the goodness of your land, though the largest commonly give the most milk: and whether you design them for breed, fattening, or the dairy, let them be such as come off a worse ground than your own, if possible. The best time to breed calves is from three years old to twelve. See the article CALVES.

For a fortnight or three weeks before a cow calves, put her into good graze; or, if it be in winter, give her hay; and be sure to keep her in the house the first day and night after she has calved, and let a little of the cold be taken off the water which you give her: the next day, if well, and she be well cleaned, turn her out about the middle of the day, and take her in two or three nights more, giving her water a little warmed every morning, before you turn her out. *Mortimer's Husbandry*, vol. I. p. 225. See CATTLE and DAIRY.

COW-LEASE, pasture, or meadow-ground, kept for feeding of cows.

COWHERD-MILK, implies milk received from the hands of the cowherd, a person whose office it is to attend upon, and look after, the herd of cows in places where they run in common.

COWL, a term used in some counties of England to signify a tub.

COW-PARSLEY, the name of a plant common in pasture grounds, and of which cows are said to be very fond. This plant should be rooted out of all pastures, for it is one of the most early plants in shooting, so that by the beginning of April its leaves are two feet high. The seeds of this plant spread greatly over the ground, and as the roots are perennial, so they are often very troublesome weeds to destroy.

COW-PARSNIP, wild parsnip, meadow parsnip, or madrep, the name of a weed that grows to near three feet high. The stalk is round, furrowed, and hollow. The leaves proceed from a large membrane or sheath. They grow

grow on long hairy stalks, and are divided and downy. The flowers grow in large umbels, are white, and consist of five irregular petals: two oval, streaked, compressed surrounded by a wing, succeed each flower.

COW-WHEAT, by some called *fox-tail*, is a pernicious weed in many countries. Its seed is something like wheat, and, according to Clusius, spoils the meal with which it is ground, by giving it a dark colour, and a bitter taste: though Mr. Ray says he could never perceive any disagreeable relish in the bread with which it was mixed. Mr. Miller says it is a delicious food for cattle, particularly for fattening of oxen and cows, and that it may be worth while to cultivate it for that purpose.

Its seed seldom grow the first year, unless they chance to be sown, or sow themselves, in autumn, soon after they are ripe. See **MEADOW FOX-TAIL**.

CRADLE, a part often added to a scythe, the better to gather the corn, when low, into swarths when it is mowed.

CRAGG, *cragge*, a name given in Suffolk to the remains of marine shells, of various kinds, and in which the greater part of the British cliffs abound.

This is a very excellent manure for cold, wet, or clay land; so that every farmer would do well to search his grounds, in order to know whether he is, or is not, possessed of this treasure, which will insure him of very large crops of corn, though his lands were before worn out by continual labour.

CRAKE, a name given in the northern counties to the crow.

CRAKE-NEEDLE, the shepherd's needle; or rather the seed-vessels of it.

CRANE'S-BILL. See **CROW-FOOT**, **CRANE'S-BILL**.

CRAP, a name given in some parts of England to darnel; and in others to buck-wheat.

CRATCH, or *critch*, a rack.

CREAM, the unctuous, or oily part of milk. See **DAIRY**.

CUBBITTING, a vice to which some horses are subject; consisting in their catching hold of the manger, sucking in of the air, and swallowing it down in gulphs, till they are often so full that they are ready to burst. Some do it only on their collar reins, and some on every post and gate they come at.

This vice is more common in London than any where else, and may either come upon horses from very low feeding, whilst they are young, and have appetites, or, perhaps, by standing much at the crib while they are shedding their teeth; for then their mouths are hot, and their gums tender and itching, which may readily make them suck in the air to cool their mouths: but young horses are the more apt to imbibe this ill habit when they stand next those that do it, for young horses often follow others. Horses addicted to this vice are but of small value; they drop a great part of their food unchewed, which makes them always look lean and jaded, with a staring coat, and consequently few of them are able to endure much labour; besides their being frequently subject to the gripes, and other disorders, owing to their continual sucking in the air. There is no method yet known that has proved effectual in the cure of this vice. *Gibson on Horses*, vol. I. p. 40.

CRIBBLE, coarse meal, or that but one degree better than bran.

CROFT, a small field or inclosure. In the northern counties it is used as a small close or inclosure, one end of which contains the dwelling-house and kitchen-garden.

CRONES, old ewes.

CROP, the produce, or the quantity of corn, grass, &c. growing on any parcel of land.

CROSS-TINING, a method of harrowing land, consisting in drawing the harrow up the interval it went down before, and down that which it was drawn up.

CROTCH, a hook.

CROW, an iron bar, with a claw at one end, used as a lever, and for making holes in the ground, &c.

CROW-FOOT, or **CRANE'S-BILL**, the name of a perennial weed common in pastures. The leaves are divided almost to the middle, usually into seven parts. The stalk commonly divides into two branches, and each of these into two more. From the corner of each division comes a flower-stalk, supporting two large blue flowers; consisting of five roundish, entire petals, succeeded by a long seed-vessel, resembling a crane's-bill. This bill-like seed-vessel is thick and rough, but not so long as in some other plants.

CROWS. See the article **ROOKS**.

CROWN-SCAB, a disease in horses, consisting in an humour that breaks out round the coronet, of a very sharp and itching nature, and attended with scurfiness. Sharp waters prepared with vitriol are generally used for the cure of this disorder: but the safest way is first to mix equal parts of marshmallow ointment and yellow basilicon together, spreading the composition on tow; and laying it all round the coronet. A dose or two of physic may be very proper to carry off the humour. *Bartlett's Farriery*, p. 206.

CUCKOW-FLOWER. See the article **LADIES SMOCK**.

CUCKOW-LAMBS, a name given in Hertfordshire to such lambs as are yeaned in April or May, because they fall in cuckow time. They are generally either the lambs of very young, or very old sheep, and occasioned by their taking ram very late in the season. These lambs are usually of the smallest sort, and therefore both ewe and lamb should have the best of keeping, in order to fatten the lamb for the butcher; for such diminutive lambs are improper to be kept for store-sheep. Besides, as these lambs are yeaned later than ordinary, it is very likely they will meet with green meat sufficient to fatten them apace, and come in season to be sold for the more money, as they are of the youngest sort, and fatted late. *Ellis on Sheep*, p. 79.

CUCKOW-SPIT, a kind of frothy substance frequently found on plants, containing one or two insects.

M. Poupert tells us, that as soon as the little creature comes out of its egg, it hastens to some plant, which it touches with its fundament, and fastens there a drop of white liquor full of air; it drops a second near the first, then a third, and so on, till it covers itself all over with a scum, or froth; this froth defends it from the heat of the sun, and also from the attacks of the spiders, which would otherwise devour it. Mr. Lisle is of opinion, that this froth is nothing more than the nightly dew which falls upon the fork or joint of the plant, and which the little insect, with its proboscis, as with a pair of bellows, works into froth.

CULMIFEROUS Plants, such as have a smooth jointed stalk, and their seeds are contained in chaffy husks.

CULTIVATION, the art of improving soils, and forwarding or meliorating the produce of the earth, by manual labour, manure, &c.

CULTIVATOR, a name given by foreign husbandmen to instruments invented for stirring the earth, on the principles of the New Husbandry. These instruments are generally called in England horse-hoes. We shall here give a description of those invented by Mess. de Chateauvieux and de Villiers, and describe those invented in England under the article horse-hoe. See **HORSE-HOE**.

Description of M. de Chateauvieux's single CULTIVATOR.

M. de Chateauvieux, having remarked the good effects of his plough in stirring the alleys between the rows of corn, rightly judged that the instrument we are now going to describe, which is much lighter and simple in its make, would answer the same end; or at least that it might be used alternately with the plough, employing this last only when a greater quantity of earth is to be turned up towards the rows of corn: "For, says he, it is to be observed, that the cultivator hardly changes the situation of the earth, but divides and breaks it in the place it is in, so as to render it loose and light, and fit for the roots of plants to penetrate with ease. This instrument, like the miner, works chiefly under ground, where it cuts the earth, divides its particles, raises it up, and lightens it. It has this further advantage, that one horse is sufficient to draw it. The cultivator, Plate VII. is composed of a beam, AB. fig. 1. the handles CD, and the share EF, which is more particularly represented in fig. 2, 3, 4, 5, and 6.

"The beam AB is three feet and a half, or four feet long. Its diameter ought not to exceed three inches at most; and, if it be square, the edges should be rounded off. It should be pierced with mortises under the letters G, H, in order to let through the cross staves I, L; in the same manner as in the fore-carriage of the plough; and is fixed to the keys K, M, or the pin a, b. The middle of the handles should be exactly opposite to the beams; that is to say, the space between them should be equal on both sides. These handles should be made lighter than those of the plough before referred to, and they should be fixed to the

the beam by a tenon in a mortise; riveted at N, and supported behind by the prop P:

"The end A of the share, fig. 3, and the two fins B, C, are made flat. The crooked handle ABC, fig. 4, should be triangular, and somewhat sharp before, to answer the end of a coulter, as in fig. 2, and 5.

"This share is to be let into a groove cut in the under part of the beam, as represented in fig. 7, and 8; and fastened there by a single ferrule, as in fig. 9. If it should cut too deep, that may be remedied by altering the position of the wheel, as in the plough, or by inserting a very small wedge g, fig. 10, between the handle of the share and the beam. If it does not cut deep enough, that wedge must be inserted, as at h, fig. 11, at the other end of the handle.

"When this instrument is used, the beam before described is to be substituted in the place of that of the plough, which is to be taken off. The two cross staves I, L, fig. 1, of the fore-carriage of the plough, are then run through the mortises G, H, of this beam, which is thereby fixed to that fore-carriage.

"This cultivator is very easily guided: the ploughman may hold it upright, or incline it to the right or left, just as the intended ploughing may require. The share and its handle enter so deep into the earth, as to be quite buried in it, if a deep ploughing is intended to be given: and in that case the tail A of the beam touches the ground. Though the share is but small, it stirs the earth at least a foot round it. Its point should be of steel, and somewhat inclined towards the earth.

"The share of this instrument, like that of the plough, may be brought as near as one pleases to the rows of corn, by placing the beam according to the frame."

Description of M. de Chateauxvieux's double CULTIVATOR.

"This instrument, Plate VII. fig. 12, 13, and 14, has two shares. It has a beam AB, and the shares CD, EF, fig. 13, which being exactly like that of the single cultivator, I have only to point out wherein these instruments differ. The beam of this should be ten or twelve inches longer than that of the other. It has likewise two mortises more, under the letters G and H, to let through the cross staves EK, IL, which bear the handles MN, OP, of the shares. The cross staves EK, IL, are riveted permanently to the beam: the handles MN, OP, are moveable upon the cross staves, to which they are fastened by the keys R, S, Q, T; so that the shares may be set at a greater or less distance from each other, according as the quality or situation of the ground may require to allow.

"This instrument stirs the earth extremely well, and does a great deal of work in a little time. Each share being about fifteen inches wide at AC, BD, fig. 14, and the distance between them from A to B, fig. 14, being about four inches, or, upon occasion, six; and the earth being stirred about two inches on each side beyond the extent of the utmost fins of the shares; each cut of this cultivator stirs about two feet breadth of ground. This double cultivator requires two horses, unless the soil be very light; in which case, I fancy one may do, though I have not yet tried it.

"If one had a mind to fix a coulter in the middle of the beam, just before the shares, I see no inconveniency that could arise from thence, provided it be a very light one.

"The way to use this cultivator is to fasten it to the fore-carriage of the plough, by running the two cross staves V, X, fig. 13, through the beam A, B.

"I would particularly recommend not to make the wood work of this cultivator too thick or heavy, and therefore by no means to exceed the dimensions I have given: for the lighter these instruments are, the more easily they are managed both by men and cattle."

Description of M. de Chateauxvieux's CULTIVATOR, with two Mould-boards.

"If, says M. de Chateauxvieux, I could have imagined, that my proposing for the use of the New Husbandry, some other instruments besides the plough, properly called, could have been looked upon as either so expensive or so troublesome as to discourage people from practising that husbandry, I should not, by any means, have thought of communicating them to the public.

"But why should not agriculture enjoy the same advantages as almost all great manufactories, in which every useful discovery and improvement, either to perfect the manufacture, or to fabricate it in less time and with less expence, is readily adopted?

"It is with a view to facilitate the various labours of cultivation, to execute them better, more speedily, and with much less expence; that I have introduced the use of my new instruments in the culture of my own lands. If others think proper to do so too, they will enjoy the same advantages. I offer them not as things absolutely necessary, for the plough alone may suffice, but as things of which I have experienced the good effects during the years 1753 and 1754, and which, for that reason, I think it incumbent on me to recommend to those who adopt the New Husbandry.

"The cultivator with two mould-boards differs from the single cultivator before described, only in the two mould-boards which I have added to it, one on each side, and which are represented in Plate VII. fig. 15. A, C, E, H, is the mould-board on the left-hand side of the plough; and B, D, G, I, the mould-board on the right-hand side. The whole of this fig. 15, represents an entire and a perspective view of the share and mould-boards.

"The mould-boards are made of plates of iron, either cast or hammered, about the twelfth part of an inch thick, which is sufficient to resist the pressure of the earth. Thicker plates than these would render the share too heavy, and it would be much more difficult to give them their proper bent.

"The two mould-boards join to the handle at HL, and lap about an inch one over the other; or else they are fastened together by rivets. They form, in that part, an angle E, H, F, of somewhat less than ninety-degrees, which is sufficiently acute to serve instead of a coulter: though a coulter may also be used upon occasion by placing it a little more forward.

"From the lower part L of the handle, the mould-board should pass underneath the fin L, G, of the single share, and follow the direction of that fin, as at G; being let in beneath, about an inch and an half, according to the pointed line LG, and firmly riveted by three strong rivets.

"The hind-part of the mould-boards is fixed and supported by the stay F, to which they are strongly riveted. This stay must have exactly the same bend as the mould-board.

"Behind the lower part of the handle is another stay, M, N, quite close to it, and about two inches below the top of the mould-boards, to which it is riveted at both ends. This stay helps to keep them firm: but its chief use is to prevent their being raised up by the pressure of the earth against their extremities A and B, which would throw their common angle H too forward, and misplace the share.

"The proper slope of the mould-boards cannot be so well described by words, as it may be conceived by the figure, which represents at F the convex inside of the one, and at Q the concave outside of the other. The distance to which the earth is turned over, when the cultivator opens it in order to make a large furrow, depends on the degree of this bending, and the space between the two upper extremities of the mould-boards E, F.

"The hind-most part of the mould-boards is cut sloping at C and D, almost in a segment of a circle. This shape helps to effect a greater division of the earth.

"The plate of iron, before it is bent, should be cut nearly in the shape of fig. 16.

"The size of the mould-boards, as well as their proper bending, depends a little upon the quality of the land intended to be cultivated. I have found that, for light soils, they need not be bent quite so much; so that the distance from C to D, fig. 15, may be twelve or thirteen, and even fifteen or sixteen inches. This same cultivator may likewise be used in stiff lands.

"Nothing hinders making these mould-boards two or three inches longer, from B to G, and from E to H; or varying some of their proportions, as the husbandman may think best.

"This share, with the mould-board is fixed to a beam, as in the single cultivator, fig. 1, where it is fastened to the fore-carriage, by the cross staves I, L.

"If this description does not convey a sufficiently clear idea of the shape and proportions of this cultivator, I will answer for its success when used. I describe it after one of

the same kind, which I have made use of for two years past with very great success."

Directions for using the CULTIVATOR, with two Mould-boards, by M. de Chateaufvieux.

"This cultivator opens the main furrow in the middle of the alley, by turning the earth over on both sides at the same time; and I have found by experience, that as much work is done by that means, by one turn of this instrument, as could be done by two, and frequently three turns of the common plough, and that without using a greater number of cattle. I must now prove this proposition; though I am persuaded that it will easily be allowed by whoever only casts an eye upon fig. 15, Plate VII. which represents the share of this cultivator." *See the article ALLEY.*

Description of a CULTIVATOR invented by M. de Villiers.

"This instrument is composed of a share, Plate VII. fig. 17, the two fins of which are eight inches and a half asunder at their extremities *a, b*. The socket *c*, which is between the two fins, projects some inches, and the hollow in it is three inches long, and one inch wide. It does not descend so low down as the fins, to prevent its touching the earth. The length of this share, from the point *d*, to the extremity of the fins *a* or *b*, is from 12 to 13 inches. At the distance of five inches from the point *d*, is a hole *e*, into which is inserted the crooked point *f*, of the iron safeguard, fig. 18, which is used in some countries in order to fasten the ear to the share of the plough. Upon the share is placed a small triangular ear *h*, fig. 20, 21, and 22, somewhat concave at bottom, that the two small ears may join exactly to the share at about an inch distance from the edge of the fins. This ear is about two inches and a half high at *a*, fig. 21, and is fastened firmly to the share of a double and angular safeguard, which covers its edge as far as *b*. It is fixed at one end of its point, which enters into the hole *e*, fig. 17, in the share, and by four small pins fastened to the ear. Fig. 18 and 19 represent this safeguard. The double ear is fastened at its other extremity, by the sheet or upright piece, *e, g*, fig. 21, which passes through the ground-rest of the hinder part of the ear, and beam, and by a piece of iron *c d* bent in a right angle. This piece of iron covers the fore part of the sheet, and rests upon the tail of the ear, against which the beam presses it very tight, by means of a wedge *e*, driven into the sheet. The piece *c d* may likewise serve to fix two mould-boards from *g* to *c*. It is nine inches high. *f* is another sheet or upright piece, which joins the beam to the ground-rest, to add to the strength and solidity of the instrument, which is increased also by the lower part of handles being fixed in the ground-rest at *i*, and traversed by the beam at *k*."

M. de Villiers, in a letter to M. Duhamel, gives the following account of his manner of using this cultivator.

"Finding it impossible to plough my alleys well when they were but three feet, or three feet and a half wide, without greatly damaging the rows of corn bordering upon them, I resolved to make them four feet wide, and took particular care to have the rows drilled very strait: but even then I found only one way of ploughing them well, which is to open the first furrow so near to the bed, that the next furrow within that may come within two or three inches of the nearest row of plants in the bed; turning over the earth of these furrows towards the alley. After two or three such turns of the plough, the ploughman will be sure not to make any mistake. It is of great importance to cut this first furrow, by which all the others are directed, quite parallel to the rows. The rest of the work will then go on regularly, and without any of that confusion which would be capable of giving many people a dislike to the new husbandry. My horses were led by hand, till they were sufficiently accustom'd to this work; but that was necessary only for the first furrow, which they afterwards follow of their own accord, so that the rest of the alley is ploughed with great ease.

"The earth of the second furrow, which is cut very near the rows, is turned over in the same direction as that of the first, that is to say from the bed.

"The third furrow is ploughed the contrary way, and the earth is then turned over towards the rows, so that the last furrow is filled up by this ploughing, and a considerable

quantity of well divided earth is turned over to the rows, for the plants to extend their roots in the spring.

"I then continue ploughing in the same direction, cutting the furrow that is turned over towards the rows as thick as possible, till the whole alley is ploughed almost close to the opposite bed, when, by turning over one large furrow on that side, the small one cut there at first is filled up. By this means, the spring hoeing is completely executed.

"I begin the second ploughing on the side where I ended the first, turning the earth over that way, which is the contrary to what was done before. When I come to the other side of the alley, I leave there, as was left before on the side I now begin at, the breadth of a small furrow, which I do not plough, but over which I turn the earth of my last furrow.

"I think this second hoeing may be deferred, when the ground does not produce many weeds: and in this case I perform it with the cultivator, which I bring almost close to the rows.

"After thus using, sometimes the plough, and sometimes the cultivator, according as the condition of the ground seems to require, I finish all my hoeings by putting two horses to the cultivator, and drawing it once or twice through the middle of the alleys, because it cuts four or five inches deeper than the plough."

M. de Villiers adds, that he could not always turn the earth over towards the rows, as M. Duhamel directs, because the wheel of his plough, getting too deep in the middle furrow, altered the direction of the share. To this M. Duhamel observes, that he himself met with the same difficulty, and found no other way of remedying it, but by opening a small furrow near the rows, by the help of which he turned the earth over towards the alleys, and then filled up the furrow immediately; taking care at the same time to turn the mould over towards the roots of the plants, so as to earth them up as much as possible. I am glad, adds he, that I have had this opportunity of giving M. de Villiers's method, because I think it a good one, and believe it will be of great service to such as may be inclined to practise the new husbandry." *Duhamel's Cultures des Terres, tome I.*

The cultivators invented by these gentlemen abroad, are many of them ingeniously contrived, but are by no means proper to be substituted in the room of the hoe-plough, because they do not turn the soil, and expose a new surface to the air as the hoe-plough does, which is an essential circumstance in horse hoeing. By the exposure of the immediate action of the air, dews, frost, &c. the soil is pulverised to a much greater degree, than when it lies at any depth, and is much more impregnated by the nutritious particles in the atmosphere, by which it is enriched so much, as to produce constant successive crops of corn, with little or no manure, as in the horse-hoeing husbandry; but without being thus turned and exposed, the land acquires no such fertility, as every farmer knows by experience.

M. de Chateaufvieux's cultivators, the single one particularly, does not turn the soil, but, as he observes, goes under ground, raising the earth a little, which falls down again in the same place, for which reason he gave it the name of a miner. Mr. Wynn Baker made use of it to hoe his drilled wheat alternately with the hoe-plough, which appears to have been one principal reason of his ill success in that experiment of horse-hoed wheat. He attributes the failure of his drilled wheat to the narrowness of his ridges; but they were five feet broad, which is some inches broader than Mr. Tull's, and others since, who have succeeded in this culture. He likewise limited his tillage to four hoeings, though he found his crops declining; whereas had he given his wheat two or three hoeings, which cost him but one shilling each per English acre, or sown some light manure upon the rows, as Mr. Tull directs in such cases, these would have kept up the fertility of his land, though he had continued to make use of the cultivators.

CULTUR, or rather *Coulter*, the piece of iron that cuts the earth before the plough-share. *See the article PLOUGH.*

CULTURE, the art of cultivating, improving, or meliorating the soil.

CULVER, a pigeon.

CURB, an iron chain fastened to the upper part of the branches of the bridle, in a part called the eye, and running over the beard of the horse.

CURN, is also the name of a disease of horses, consisting in a swelling at the junctures of the bones of the hind part

A. Hattori, compiler.

part of the hock, forming a pretty large tumour over the back part of the hind leg, attended with stiffness, and sometimes with pain and lameness.

A curb proceeds from hard riding, strains, blows, or kicks. The cure at first is in general easily enough effected by blistering, repeated two or three times, or even oftener. If it does not submit to this treatment, but grows excessive hard, the quickest and surest way is to fire with a thin iron, making a line down the middle from top to bottom, and drawing several lines in a pennyform manner, pretty deep; and then to apply a mild blistering plaister or ointment over it. This method will entirely remove it. *Bartlett's Farriery*, p. 262.

CURRY-COMB, an iron instrument full of small teeth, used for currying horses.

CUSPATED flowers, those whose petals or flower-leaves end in a point.

CUTTING-BOX, a machine for cutting fodder; as straw, hay, haum, &c. into small pieces, commonly called chaff, for the use of cattle.

We have given, on plate VI. fig. II. a cut taken from the *Museum Rusticum*, Vol. VI. page 10, of an improved cutting-box. The improvement consists in what the inventor calls a presser, which is a piece of wood as long as the box is wide, with three iron tongues in it, like those of a hay-fork. These tongues are put into the bundle of hay or straw to be cut; and by means of a rope fixed thereto, and extending under the box, the presser is forced down by the left foot of the cutter, and consequently the bundle kept tight. By this means the chaff is cut with great ease; and, after every cut, the operator rises his left-foot, pushes his sheaf or bundle forward with his left-hand, then presses it down again with his foot and takes another cut. In this manner, he continues working, till the whole bundle is reduced to chaff.

This description will be very easily understood by inspecting the figure above referred to, where A is the presser, B a large knot at the end of the rope, which fastens it to the presser. C the rope, D F the slit in which the rope moves, as the cutter pushes the bundle forward. E the loop in which the cutter puts his left-foot. F the box to contain the hay, straw, &c. The knife is not delineated in this figure, as the manner of placing it is sufficiently known.

A correspondent of the editors of the *Museum Rusticum* tells us, that he never gives his horses any pure corn, but always makes use of his cutting box, in which his servants cut his horse-meat, which consists of unthreshed oats, tares, pease, or beans. They cut off the heads where the corn lies, and take besides a cut or two of the straw to mix with it. This he gives to his horses instead of corn, it being a very nourishing food, and of which they are very fond. Nor is there any danger of their being surfeited with it, which they often are with pure corn; many of their disorders arising from their being over-fed.

I cannot, continues he, enough commend the use of a cutting-box, though I am persuaded the ploughmen will endeavour to prepossess their masters against it, because the cutting of the horse-meat is pretty tough work, and they do not, in general, love to do more than they can help.

When oats, beans, pease, or tares, are intended to be thus cut for horse-meat, it is best to mow them before they are quite ripe, as by that means fewer of them will be lost by shaling, and the straw, or stalks, will be of a better quality, and more nourishing for the cattle.

Care must, however, be taken that the crop be well dried before it is housed, lest it heat in the mow and take damage, if not set the barn, or stack, on fire. *Museum Rusticum*, Vol. I. p. 258.

Mr. Marshall, in his *Rural Economy of the Midland Counties*, under the head of barn-management, says, "Chaff-cutting, as it is pretty generally termed, but here provincially 'straw cutting,'—is in great use. Not, however, the ordinary practice of cutting hay and straw into what is, in most places, called chaff or cut-chaff, but, here, more properly 'cutmeat;' but by reducing oats, in straw, into this species of fodder; which is given, not to horses only, but to cattle; especially fattening cattle. It is thought to give, not only fatness, but a fineness of skin, to all sorts of stock.

"The chaff-box made use of, here, is of a peculiar construction. It unites, in some measure, the old single-hand machine, and the modern one with a wheel of blades.

This, in use here, has a long upright knife; but feeds itself; by which means the cutter has both hands at liberty; for the knife. It is made at or near Birmingham, and sold at most of the market towns of the district. It is, however, somewhat complex; and fitter for a man who makes a business of 'straw cutting,' than for a farmer's servant.

"The price of cutting, three farthings a heaped bushel; but it is cut extraordinarily fine."

CYDER, or *Cider*, a liquor made from the juice of apples, expressed and fermented.

A Herefordshire planter has given us the following method of making cyder in that county, which has been so famous for this liquor.

"The worse, says he, the apple is for the table, the better it is, in general, esteemed for cyder, such as grow all over this country, and are, in a manner, wild, harsh, and crabbed to the taste. These go under various names, as the redstreak, the white and green musts, the gennet-moyl, the stocking apple, the summer and winter fillets, &c. &c. of all which I prefer the first, provided it is a good sort, which is not always the case, particularly in some parts of Worcester and Gloucestershire, where they grow in great plenty.

"I have long laid down from experience, the best mistress; that, first, the more red an apple is in its rind, the fitter it is for cyder; that is to say, if it is at all fit; for I have seen an apple of a very deep red, by some called sopsy-wine, quasi sopped in wine, which was worth nothing for this purpose.

"Secondly, that the paler the rind, the worse the juice.

"Thirdly, I have found it a maxim, in general true, that a sweet apple with a tough rind will always yield a good vinous liquor.

"Forthly, The more yellow the flesh of the fruit, the better and finer coloured will the cyder be.

"The few maxims, not too scrupulously adhered to, have been of great service to me in life; for though I have a high opinion of them, I do not absolutely rely on them. There is no rule so general, but an exception may be made to it; but a man of reflection, with a few well-founded rules, will seldom be at a loss how to act in this, or in any other case.

"I seldom suffer my apples to be gathered till they begin of themselves to drop from the trees; nature then tells me they have, for the most part, acquired a proper degree of maturity.

"Great care is taken in the gathering of them, for fear they should be bruised in the operation; and this I have always found a very necessary precaution.

"As they are gathered, I have them sorted, according to the several degrees of ripeness they are of, making, in general, three sorts, which a little experience easily teaches to separate properly, the difference being apparent enough at first sight.

"As fast as they are gathered and sorted, they are carried under a shed prepared for that purpose, and laid in large heaps to meliorate: this practice I cannot enough recommend, as being of great service to the liquor, improving its quality, and making it keep, without comparison, better; and all this is caused by a little sweating in the heap.

"Yet, good as this practice may be, some avaricious planters cannot be induced to adopt it, because, say they, the apples fresh from the tree will yield better; as, of these last, about twenty bushels will give a hoghead of cyder; whereas, of the other apples, which have been heaped, it will take about twenty-five to make the same quantity.

"I suffer my apples to lie in the heap a longer or a shorter time, according to the nature of them, such as are harsh and solid requiring to lie longer, by several days, than those that are mellow and pulpy; and the degree of maturity the apples had attained before they were heaped, makes also some difference in this respect.

"I have already observed, that I divide my fruit into three several sorts, according to the state of its maturity: I have now to add, that, from these three sortings, I have no less than six several kinds of cyder, each different from the other in taste, flavour, and quality.

"As fast as the fruit is ground (I need not, I think, mention that I used the ripest first) the pulp is put into a large vat near the press: at the bottom of the vat is a tap, through which a considerable quantity of the prime vinous

juice will run without any pressing, induced by its own weight only: this produces my best cyder; and I always tun it up by itself: the pulp is afterwards pressed in the usual way. The same process is used in all the three sortings of apples; by which means I get, as I said before, six sorts of cyder.

"The first runnings from the vat I immediately put into the vessels in which it is to remain; only, if it happens, by any accident, to be too foul, I strain it first. I allow here but a small vent-hole, and when it has done working, I fill the vessel with some of the same liquor reserved for that purpose: I afterwards, by degrees, close the vent till it is finally and well-stopped.

"As to the juice, which undergoes the action of the press, I put this, as soon as it runs off, into vessels, where I suffer it to remain about thirty hours, according to the season, till the fæces are precipitated, or fallen to the bottom; after which I draw it off, and tun it up in the vessels in which it is to remain, with the precautions however, above-mentioned, when I treated of the first runnings.

"The kind of vessels I use, and which I think by far best, are upright hogsheds, broader at the upper head than at the bottom; and I often, after my cyder has done fermenting, cast two or three handfulls of wheat-bran into each vessel, which serves to thicken the head or cream of the liquor, and makes it keep better.

"I am very careful with respect to the vessels into which I put my cyder, always avoiding new ones, if possible, as they give the liquor a twang, or bad taste, and hurt its colour; my usual way is, to season all my new casks, that I possibly can, with small beer, which I use in common in my family, though I live in a cyder county; and if I have not an opportunity of doing this, I scald them with water, in which a considerable quantity of apple-pulp has been boiled.

"If a vessel is not sweet, it may easily be cured, unless very bad indeed, by putting some unslacked lime into it, adding some cold water, stopping it close, and rolling it about till the noise within is no longer heard.

"I have often found it of great use towards enlivening the liquor, to slice about a dozen sweet apples into a hoghead: I am also inclined to think it makes it keep better.

"The best cyder I ever had was a few years ago, when I put in each hoghead about three quarts of good wheat, first boiled and hulled, so as to have, in some measure, the appearance of boiled rice.

"When I am obliged to put any cyder into a cask I suspect, and afterwards discover it has given the liquor a bad taste, I cause some mustard-seed to be ground in a quern with some cyder: this mixture, being put into the hoghead, is often of great service, and restores it to its original good taste.

"Cyder, when it is tunned, is very apt to lose that fine mild spirit which renders it so pleasant and brisk a liquor; therefore great caution should be used with respect to the vent. The wild, furious, and ungovernable spirit should be suffered to escape; which may easily be effected by leaving a small vent open for a few days; after which the barrel must be close stopped, for if it gets any vent, the liquor will stand a great chance of being entirely spoiled; on the contrary, if well bunged, though it may be dead and flat at first, it will soon recover itself, mature, and be fit for drinking. This particular part of the management of cyder is critical, and depends greatly on the temperature of the air, so that it is impossible to give any absolute directions about it, as something must still be left to be learned by experience, and governed by discretion.

"I must give one particular piece of advice to such as intend making cyder, which is, that they diligently watch the alterations in it upon every change of weather, as a small neglect, at such times, is often fatal to many hogsheds, and the danger is much greater in summer than in winter. There is scarcely any disease incident to this liquor, but what may easily be cured by a timely application: if it is only a little inclined to tartness, wheat, managed as above-mentioned, will cure it; and the same thing is also very good to preserve it, when it is drawn out of one cask into another: the quantity when the liquor is tart is about half a peck to a hoghead; I have sometimes even put a quart more.

"This simple remedy will, I say, often cure the tartness I mentioned; but sometimes, when it is very thick and sourish, it may be necessary to raise a new fermentation, to

purge off the impurities, and make them subside: this may be soon done by bruising the flesh of a few apples to a pulp with some of the liquor, and putting the whole into the bung-hole of the vessel; this will raise a ferment, and cure the cyder: when that is over, it will be proper to draw it off into another cask; and it will also be a very useful precaution, to put into the last mentioned vessel about a quarter of a peck of wheat, prepared as I have already directed: this will give it new life and spirits, and make it keep better, and drink much pleasanter.

"I have sometimes also used another method to cure tart cyder; but it has not always succeeded with me; why, I cannot say, as some people who live not many miles from me, have great dependence on it. Something may depend on their soil differing from mine, though this may, to some of your readers, seem to have a very remote analogy to the case in hand. The remedy is, to break half a dozen new-laid eggs, and beat them up, shells and all, till they are brought to a frothy oil: this is put into the bung-hole of a hoghead, and, as I am credibly informed, sometimes proves a very efficacious remedy: it has succeeded with me, but not so often as to induce me to depend much upon it; I mention it, however, as it may prove of more efficacy with others than it has with me.

"An industrious planter will, by the constancy of his observations and remarks, always have it in his power to cure his own liquor by receipts of his own discovering; and for this purpose I would recommend, that he be continually making experiments, and that whatever trials he makes, be in various modes and proportions; for the remedy that may be of no service in one form, may possibly be very efficacious when altered with judgment, which judgment can only be acquired by experience and observation.

"It is to be noticed, that, if the cyder is acid, and at the same time clear, it is in a very dangerous state, being but rarely recovered: therefore, in general, when this is the case, the cure is scarcely worth attempting.

"I have often used wheat for the recovery of my cyder in other forms, sometimes putting about half a peck, underground, into a hoghead for it to feed on; at other times I have made dough of coarse meal with the bran in it, adding some leaven, using no salt, and putting warm cyder, or white wine, instead of water, in the mixture: this dough I make into lumps about as large as my fist, and thrust them into the bung-hole of the hoghead, the quantity being about half a peck of the meal to a hoghead.

"Many mix different kinds of spice with their liquor, particularly ginger, which they think of great service; but I never use it now, seldom having found any great effect resulting from it, and being of opinion that it renders the cyder more unwholesome than it can possibly in its own nature be; for though the ginger may not make any very sensible alteration in the immediate taste of the liquor, it must, I think, strongly impregnate it with its fiery particles, and thereby greatly irritate the mass of blood, and inflame the lungs of such as drink any quantities of liquor wherein it has been infused: others, however, may differ in opinion from me; I know, indeed, many that do so, therefore, I only declare my opinion. *Museum Rusticum*, vol. II. p. 37.

It is of great importance in the making of cyder, that the fruit be thoroughly ripe. The juices of unripe apples retain their harsh, sour taste, in spite of all endeavours, and never acquire that racy mellow flavour, which the sun only can bestow. Sweating together in a heap will, indeed, give them an artificial ripeness; but this is not equivalent for that which they receive from nature, which though it receives some assistance from the industry of man, can never be completely imitated by art.

It should, therefore, be the first care of every one concerned in the making of cyder, to let his apples hang upon the tree till they arrive at full maturity. But no certain time can be assigned for this: it varies with the nature of the fruit, and the circumstances of the season. Different apples have different times of ripening; and the same, according to the weather, change their time considerably from one year to another: but signs there always are sufficient to direct the husbandman. The brownness of the kernels, their rattling in the apple, the fragrant smell of the fruit itself, and its spontaneously falling from the tree in calm weather, are certain indications, which, in all kinds, may be depended on. It is, however, an useful caution in this, as in every other case, to err on the right-

side; and to let the apples hang too long, rather than too little. Summer fruit, indeed, will suffer by this method, grow pulpy, dry, and mealy, and afford little or no juice. In every other case the rule is good; and in the best fruits, most. The harsher kinds can hardly hang too long, for they daily mend upon the tree: their juices mellow, throw off their crude and watery parts; and consequently, as the crude juices lessen in quantity, the apples improve proportionably in quality. They may hang upon the tree as long as the weather can be expected to continue open: but severe frost should be most carefully avoided; because it destroys the texture of the fruit so much, that even cold water, the only remedy in such case, will not restore it to its former state: for as all fluids enlarge their dimensions when frozen, the containing vessels of all succulent substances must be thereby burst, and this has upon the fruit an effect similar to a bruise; or any other cause that destroys the vessels, whereby the extravasated liquors soon putrify. From this cause it is that the strongest forest trees are often rent asunder in very severe frosts.

When your apples are fit for gathering, it is essential to choose dry weather for that purpose, for water is a bad ingredient in all vinous liquors, and your fruit should therefore be guarded from it with peculiar care. The wet which adheres to the apples after rain or dew, or even the smaller quantity of moisture which they might contract by falling or lying upon grass, is sufficient to impoverish your cyder in a sensible degree. Gather your fruit therefore in the driest day, and in the driest part of it, when the dew is thoroughly exhaled; and, of choice, gather it by hand. This method may, perhaps, be troublesome and difficult in plantations of great extent, and where the trees are very tall: but wherever it can be used it is of great advantage, and certainly quits cost. You then can choose your apples, and leave upon the tree those which are not of a sufficient ripeness: you save your fruit from bruises, and your trees from the damage they frequently receive by violent unskilful shaking.

The gathering by hand is so essential, especially for winter fruit, which is to be sweated for a considerable time, that it should not by any means be dispensed with; because, as every wounded part of an apple will rot in the sweating, a very great loss must be occasioned, both in the quantity of the fruit; and in the longer time taken up in wiping and rubbing off every speck of rottenness upon each single apple. This last labour is indispensable; because, otherwise, the putrid taint would ever remain in the liquor. Those who plead the want of time, where a great quantity of fruit is to be pressed, may be answered, that it would be more to their advantage to have only half the quantity of good cyder than the whole of indifferent; and the gathering may certainly be expeditiously performed by means of step-ladders. The apples may be put into baskets, as they are gathered, and thereby preserved free from hurt, and the tree will not be injured, as the support of the ladders here recommended is independent of the tree. However, for those who will follow the contrary practice, the best method is to cover the ground under the trees with a sufficient thickness of straw to save the apples in their fall, and to lay blankets upon the straw; then, with an easy motion, to shake the boughs successively, removing, at every shaking, the apples already fallen, that they may not be bruised by the next. By these means all your apples are kept dry, and, for the most part, free from bruises; and with a little additional care you may also, in this method, separate the fruits according to their ripeness: for if you proceed regularly from bough to bough, and give each a gentle swing, the ripest will fall first, and the unripe remain upon the tree till more violent motion brings them down.

Windfalls, as they are generally termed, bruised apples, and those which have not been well ripened, should not by any means be mixed with the choice fruit: for if they are, it would be in vain to expect good cyder: the quantity of it indeed may be large, but it will always be proportionably bad. This fruit need not, however, be thrown away, excepting only that part of it where the bruise appears black and mouldy; for a very little of this would communicate an offensive taste to the whole liquor. The rest will make inferior kinds of cyder; and if care be taken that the windfalls do not lie too long upon the ground, and if keeping cyder be not expected from bruised apples, they will answer tolerably well: nay, Mr. Newburg tells us, in a letter subjoined to Mr. Evelyn's Pomona, that a neighbour of his assured him he had made a quantity of

very good cyder with windfalls, which he ripened by sweating them for about a month; that they were beaten off the tree earlier than the season when nature would otherwise have compleated their maturity; but that all the neighbours of this person, who pressed their untimely fruit as soon as it fell, had a crude, austere, indigested liquor, not worth the name of cyder.

The sweating of the apples has, however, been made a matter of some dispute. The writer of the twenty-fourth letter in the Dublin Society's Weekly Observations, disapproves of it for choice ripe fruit, and instances his having been informed of some curious gentlemen who carried their thoroughly ripe apples directly from the tree to the grinding mill, without any previous sweating; and obtained from them some of the best cyder they ever tasted. As to the winter fruits, he thinks it probable that the necessity of sweating them might be removed, by leaving them upon the trees somewhat longer than is necessary to ripen them; "no reason," (says he, without having perhaps sufficiently attended to the benefit which fruit receives from being discharged of its watery parts) "hitherto appearing to make us think that this fermentation by sweating serves any other use than to increase the degree of maturity which the fruit had acquired upon the tree—It is indeed possible," continues he, "that it may answer farther purposes, and dispose the fruit to an easier emission of its juices: and as our reasonings upon nature frequently lose their way, where experience does not guide them, it is from trials only that we can form a judgment to be depended on: recourse must therefore be had to actual experiments, which in this case are easy, and will certainly quit cost: for which ever way the question be determined, something must be found very well worth the knowing. Should sweating answer some purpose not to be attained upon the tree, it will, when once discovered, ascertain the nature, the use, and the degree of sweating: or should nothing of this kind appear, it will correct a practice, which, if it does no good, must certainly do mischief; since it is evident to common sense, that if maturity be all that is wanting, it is more perfectly and more naturally attained upon the tree." However, till this is determined by experience, it will be right to continue the practice of sweating every apple; for as to windfalls, and other hard and unripe fruit, it is out of dispute, that they are deprived of natural maturity; they must be assisted by art.

Upon the whole, there seems in this case one rule which may be allowed for all fruits, namely, to press their juice for fermenting at the time when the fruit itself is in the greatest perfection for eating. Experience teaches us, that there are few apples which do not require time for their being mellowed, before they attain to the highest flavour. The golden pippin, for example, is in its greatest perfection when kept till October; and in favourable years it will retain its flavour and juiciness even till Christmas, or longer. The nonpareil does not attain its chief excellence till near Christmas, and after that it continues in perfection several weeks. It is therefore during the time these apples continue in perfection that they are fittest to be pressed for cyder; and the same will doubtless hold good of the other sorts, none of which should be pressed before they have attained their highest flavour, nor after they have begun to lose it. A principal advantage accruing from the sweating of apples is, that the fruit is thereby deprived of the watery parts of its juice, which would only weaken the liquor; while its pulp yields a greater quantity of the enriched juice after it has been mellowed.

The material points to be observed in the sweating of apples are, that the fruits be separated according to their different degrees of ripeness, and that the floor on which they are laid be as dry as possible. The more strictly the former of these cautions is observed, the better it will be; and the more the fruit in every heap is alike in its maturity, the sooner the sweating will be over, and the less damage will accrue to the ripest and best apples in the heap. However, if care be taken not to mix any that are very ripe with others that are very green, the injury will not be great: but if this should be neglected, as it too frequently is, either the ripe apples will rot, or the green ones will remain unmellowed; and in either of these cases, the cyder will be considerably lessened in its value. Boarded floors will best answer the intention of the second caution, because they are driest; earthen floors, however, if covered some inches deep with wheat, rye, or oat straw, will do tolerably well. It is likewise essential, for the better preservation

vation of the apples, that they do not touch the walls or sides of the store-room in which they are laid to sweat. To heap them up in the orchard, or any where else upon the grass, or on an uncovered floor where the rains and dews have free access to them, is a sure way to make the cyder weak and watery, and frequently musty and ill-tasted.

Sweating being then undeniably necessary, at least for unripe, hard, and winter fruit, the husbandman, who makes a considerable quantity of cyder, will find a great convenience in having near his orchard a building, of which his mill and press should occupy the lower floor, and his apples be sweated in that above, from whence they may be conveyed into the mill by a proper trunk. The duration of the time of sweating is best determined by the smell of the fruit, that is, whenever it emits a full scent of the apples, they are fit for the press. Different kinds require different lengths of time, viz. from eight days, to six weeks. The harsher the apple is, the more time it wants.

Apples that have laid any time in heaps, are generally covered with a clammy moisture, proceeding from their sweating. This should be well wiped off; for it is a watery juice, which would impoverish the cyder; and at the same time every bruised and rotten part of the apple should be carefully cut out, and thrown away, and it should be cleared of its stalk; because the former would give a putrid taste, and the latter too much roughness, to the cyder.

The common practice is to carry immediately the apples from the heap where they have been sweated, to the mill, and then to grind them; but if we attend to the length of time during which they will remain in a succulent state after having been sweated, carefully wiped dry, and properly laid up in a place of preservation; we shall find, that if these directions are duly observed, the fruit will continue in a perfectly sound state, and fit to be made into cyder, till it may be convenient for the husbandman to press it: but before he does this, or rather before he sweats his apples, he should take care to sort them, or at least all the most valuable kinds, and particularly the fire, under-leaf, fox-whelp, and golden pippin, which hitherto have not been found to do so well in mixtures, as each of them does by itself.

The juice of the apples is obtained either by pounding the fruit in a trough, or grinding it in a mill. The former of these is least approved, because it is so tedious as to suit only small quantities, and the work is performed by it unequally, and with waste; much of the liquor being dashed out of the trough by the beating, and some of the apples being hardly broken, when others are reduced to a perfect pomice.

There are several engines used for grinding the apples; but one in particular, resembling a tanner's mill, is used in many parts of England. It consists of a circular trough in which apples are bruised by a large flat stone moved round upon its edge. This engine we have represented on Plate VI. fig. 8, where M is the stone set upon its edge; N, the spring-tree bar, or that to which the horse is fastened; P, Q, R, the circular trough in which the stone moves; T, L, V, compartments, or divisions for different sorts of apples.

When the apples are ground, some carry them directly to the press, but others empty them out of the trough into tubs, or large, wide, shallow vats. This work is done with most ease by broad wooden shovels: which should also be used to turn the pomice in the vats five or six times a day, to prevent any fermentation; the whole of this operation being chiefly intended to give the pomice a red colour, which afterwards heightens that of the cyder, and brings it to a deep, fine amber. This business is over in two days.

From these vats the pomice is carried directly to the presses, of which there are several kinds: we have given figures of two kinds on Plate VI, where fig. 9, is the small cyder press, by which the juice is pressed out of the pomice by means of a stone, or block of heavy wood, cut in the form of the frustrum of a cone, and moveable about the center. The pomice is spread upon the bed of the press, where a conical presser is turned round by means of a lever inserted upon its basis, by which means the juice is forced out, and conveyed by notches cut in the bed to the vessel, by means of a spout, and represented in the figure.

Fig. 10, is a large cyder-press, where A B is the base with its supporters. C, C, the cheeks, which are upright beams, whose lower extremities are sunk in the earth, where they are firmly fixed by cross-bars and masonry.

They are connected at the top by two beams, the lowermost of which contains the nut, or female screw. D is the screw with its wheel; below which is the bearer, or large piece of timber on which the force of the screw is exerted, in order to sink the beams crossing the planks that cover the pomice or cheese, as it is then called. G, G, are the planks on which the pomice is deposited in hair bags, in order to be squeezed: these planks are cut in notches to conduct the liquor to a vessel properly placed to receive it. The bed of this press is supported on a massive work of masonry. It is the wheel which forces down the screw and bearer upon the pomice laid in hair bags upon the bed of the press. This is done by turning the wheel H round; for by that motion the cord is wound round its axis, and by that means the wheel fixed on the bottom of the screw is turned round, and the bearer together, with the cross planks under it, are forced down upon the pomice, laid in bags upon the bed.

These bags hold about two or three bushels, or as much as the mill can grind at once; and these are heaped over each other till the press is full. The larger presses will hold from eight to fifteen bags, which yield from one to two hundred gallons of liquor, according to the largeness of the cheese. To perform the work neatly, it is necessary to have two sets of these bags, for they clog and fur in pressing, and, consequently, become unfit for use till they have been washed and dried; so that while this is doing, either the press must stand, or another set be ready to employ it.

Some, instead of hair-bags, lay long straw under the pomice, the ends of which they turn up over it; then cover the pomice entirely with fresh clean straw, upon which they spread another layer of pomice, and so on, alternately, till the press is full. Either of the above methods will do: but those who are desirous of doing the work in the neatest and best manner, generally use bags.

It is usual to dispose of all the liquor pressed out of the cheeses, the same way, and without distinction: but if the analogy holds, as it surely does, between cyder and other vinous liquors, this must be a considerable error. Experience has sufficiently shewn, that in making wines, there is a very great difference between the first yieldings of the grapes, and the juices which are afterwards extracted by hard pressings; and this difference is always in favour of the former; so that, if the same be true of cyder, the richest, and choicest kinds are lost, by an imprudent mixture of the whole.

It is an opinion generally received, and the writer of the letters in the Dublin Society's Weekly Observations, already mentioned, has adopted it; namely, that summer fruit do not make good cyder. "Summer fruit, or sweet apples, says he, afford only a weak, pert, windy juice, agreeable enough to the palate from its liveliness and tartness, but in a great degree unwholesome. It has no body, and therefore will not keep, and scarcely deserves the name of cyder." But sir Paul Neile, whose reasoning we shall give in his own words, judged very differently.

"I assert, says he, that the best apples will make the pleasanter, which in my opinion is the best, cyder; and I account those the best apples, whose juice is the pleasanter at that time when first pressed, before fermentation. I shall need, besides the experience of the last ten years, only to say, that it is an undeniable thing in all wines, that the pleasanter grapes make the richest and pleasanter wines, and that cyder is really but the wine of apples, and not only made by the same way of compression, but, left to itself, hath the same way of fermentation, and therefore must be liable to the same measures in the choice of the materials.

"This truth was not formerly owned, by reason that in Herefordshire, and those countries where they abound with pippins and hard apples of all sorts, they make cyder of both kinds and used them alike; that is, as soon as they had ground and pressed the apples and strained the liquor, they put it into their vessels, and there let it lie till it had worked, and afterwards was settled again and fined, as not thinking it wholesome to drink till it had thus, as they call it, purged itself; and this was the frequent custom of most men in the more southern and western parts of England also. Now, when cyder was thus managed, it is no wonder that when they came to broach it, they for the most part found their pippin cyder not so pleasant as their moyle or red-streak cyder; but to them it seemed a wonder, because they did

not know the reason of it, which I shall next explain: for till they knew the reason of this effect, they had no cause but to think it was the nature of the several apples that produced it; and consequently to prefer the hard apple cyder, and to use the other apples, which were good to eat raw, for the table, for which the hard apples were totally improper.

"To shew that, in Herefordshire, they knew not what was the true cause why their pippin-cyder was not, as they used it, so good as the cyder made of hard apples, I say, that for all liquors which are vinous, the cause that makes them sometimes harder or less pleasant to the taste, than they were at the first pressing, is the too much fermenting. If wine or cyder by any accidental cause do ferment twice, it will be harder than if it had fermented but once; and if it ferment thrice, it is harder and worse than if it had fermented but twice; and so onward, the oftener it ferments, and the longer it ferments, it still grows harder.

"According to the old method of making and putting up the cyder, they took little care to put up only the clear part of their liquor into their vessels or casks. Now pippins being a softer fruit, are in the mill bruised into smaller particles, than the harder sorts of apples; and consequently more of those small parts pass the strainer in the pippin cyder, than in the cyder of hard apples. This causeth a stronger fermentation, and, according to my former principle, a greater loss of the native sweetness, than in the hard apple cyder; and not only so, but the lee of the hard apple cyder being compounded of greater particles than the lee of the pippin cyder, every individual particle is in itself of a greater weight than the particles of the lee of the pippin cyder, and consequently less apt to rise upon small motions. When the fermentation of the hard apple cyder is once over, a second fermentation seldom happens, unless the vessels be stirred: but in pippin cyder it is otherwise; for if the gross lee be still remaining with the cyder, it needs not the motion of the vessel to cause a new fermentation; but every motion of the air, by a change of weather, will cause a new fermentation, and consequently make it work till it hath destroyed itself by losing its native sweetness. This alone hath been the cause why commonly when they broach their pippin cyder, they find it so unpleasant.

"What first gave me the hint of this, is that in divers parts they make three sorts of wine out of one and the same grapes; that is, they first take the juice of the grapes without any more pressing than what comes from their own weight, and the bruising they receive when put into the vat; which causeth the ripest of these grapes to break, and the juice, without any pressing at all, makes the pleasantest and most delicate wine. The second sort they press a little, which makes a wine neither so pleasant as the first, nor so harsh as the last, which is made by the utmost pressing of the very skins of the grapes, and is, by much, more harsh than either of the other two. Now I presume the cause of this at least in part, to be, that in the first sort of wine, which hath little of the substance, besides the very juice of the grape, there is little lee, and consequently little fermentation; and because it doth not work long, it loses but little of its original sweetness. The second sort, being a little more pressed, hath somewhat more of the substance of the grape added to the juice, and therefore, having in it more of that part which causes fermentation, ferments more strongly, and is therefore, when it hath done working, less pleasant than the first sort, which worked less. For the same reason the third sort, being most of all pressed, hath most of the substance of the grape mingled with the liquor, and worketh the longest: but at the end of the working, when it has settled and is clear, it is much more harsh than either of the two first sorts. The thought of this made me first apprehend, that the substance of the apple mingled with the juice, was the cause of fermentation, which is really nothing else but an endeavour of the liquor to free itself from these heterogeneous parts which are mixed with it: and when there is the greatest portion of those dissimilar parts mingled with the liquor, the endeavour of nature must be stronger, and take up the more time to perfect the separation, which, when finished, leaves all the liquor clear, and the gross parts called the lee, settled to the bottom of the vessel. Nor did this apprehension deceive me: for when I began to separate a considerable part of the lee

from the cyder before it had fermented, I found it to retain a very great part of its original sweetness; more than it would have done if the lee had not been taken away before the fermentation; and this not once, but constantly for seven years.

"The method which I used was this: when the cyder was first strained, I put it into a great vat, and there let it stand twenty-four hours at least, but sometimes more; if the apples were more ripe than ordinary: then, at a tap, before prepared in the vessel, three or four inches from the bottom, I drew it into pails, and from thence filled the hoghead, or lesser vessel, leaving the greatest part of the lee behind. During this time that the cyder stood in the vat, I kept it as close covered with hair-cloths, or sacks, as I could; that so too much of the spirits might not evaporate.

"Now possibly I might be asked why I did not, since I kept it so close in the vat, put it at first in the vessel: to which I answer, that had I put it at first into the vessel, it would possibly, especially if the weather had chanced to prove wet and warm, have begun to ferment before that time had been expired; and then there would have been no possibility to separate any part of the gross lee, before the fermentation had been wholly finished; which keeping it only covered with these cloths was not in danger: for though I kept it warm in some degree, yet some of the spirits had still liberty to evaporate; which had it been in the hoghead with the bung only open, they would not freely have done; but in the first twenty-four hours it would have begun to ferment, and so my design had been fully lost: for those spirits, if they had been too strongly reverberated into the liquor, would have caused a fermentation before I could have taken away any part of the gross lee. The great mystery of the whole lies in this; to let so many of the spirits evaporate, that the liquor shall not ferment before the gross lee be taken away: and yet to keep spirits enough to cause a fermentation when you would have it; for if you put it up as soon as it is strained, and do not let some of the spirits evaporate, but suffer the gross lee to be separated by its own weight only, without fermentation, it will ferment too much, and lose its sweetness; whilst on the other hand, if none be left, it will not ferment at all, and then the cyder will be dead, flat, and sour."

Experience taught sir Paul, that it was necessary to delay the fermentation till late, or till the cold weather had come in, as he informs us, when he says, "It is necessary that the apples have a little time to sweat in the house before the cyder is made; but not too much: for if they be not full ripe before they are gathered, and not suffered to lie a while in the heap, the cyder will not be so pleasant; and if they be too ripe when they are gathered, or lie too long in the heap, it will be very difficult to separate the cyder from the gross lee before the fermentation begins; and in that case it will work so long, that when it fines, the cyder will be hard: for when the apples are too mellow, they will break into such small particles, that it will be long before the lee settles by its own weight only; and then the fermentation may begin before it be separated, and so destroy your intention of taking away the gross lee. And if the apples be not mellow enough, the cyder will not be so pleasant as it ought to be."

To the cause above assigned by sir Paul Neile for the liquors fermenting too much, another may be added; namely, that as the summer fruits are fermented earlier than the hard apples, the warmth of the weather hurries the fermentation on too fast, and by this means renders the liquor much less palatable: or it may even hurry it beyond the vinous state, till the acetous fermentation begins. The sweetness of the summer fruits make them likewise more liable to ferment too much; whereas, the sour roughness of hard apples retards that operation, and makes a longer time necessary to perfect the vinous fermentation. These causes render it necessary that great care be taken in preparing the juice as directed by sir Paul, and that there be a cellar in which the heat is suited to carry on as slow a fermentation as possible. If the maker of the cyder is not provided with such a cellar, the juice of the apples may be buried in cold spring water, as before mentioned, and be kept there till the temperature of the weather becomes fit for its being fermented.

"What has been said of the time for making the pippin cyder, may, adds sir Paul Neile, with due allowances, for the nature of the apples, serve for all other summer fruit; as the Kentish-codlin, marigold, gilly-flowers, summer-pearmain, summer-pippins, Holland-pippins, go den-pippins,

pippins, and even winter-pearmain. For though they must not be made at the same time of the year, yet they must be made at the time when each respective fruit is in the condition before directed for the pippin: Nay, even in the making of that cyder, you are not tied precisely to that particular time, but, as the condition of the year hath been, you may make your cyder one, two, three, or four weeks later."

When the pressing of the apples is finished, the most careful makers of cyder strain their liquor through a hair sieve, to separate from it the coarsest dregs; which is a practice every way adviseable. It must then be left to itself, till it has undergone the necessary fermentation, and deposited its grosser lees. To this purpose some put it immediately into hogheads, others into large tubs or vats, and the most curious into a vessel intended for that very use, wide at top, and growing narrower all the way down to the bottom, near which is a tap to draw off the liquor. This vessel is fixed upon a stand, or stilling, and frequently contains from five to twenty hogheads. In these vessels the heavier lees subside, and the lighter form at top a crust, which by its sinking, afterwards, gives timely notice that the ferment is gone off, and that the liquor is fit for racking. Some gentlemen, who spare no pains to make their cyder as fine as possible, think that the excellence of the liquor depends greatly on catching the very instant when this crust breaks; and in order to be sure of it, they set a person to watch and give immediate notice of the crack or noise which the crust makes in breaking. They hold this to be the critical time for racking off the liquor, and maintain, that so much of its spirit is evaporated very speedily after, as to render the cyder irrecoverably vapid. This, therefore, should be carefully attended to; and upon the first appearance of the crust's falling, the cyder, which is then become tolerably fine, should be drawn off the grosser lees, and turned into the hogheads. The usual time taken up in this primary fermentation is from thirty-six to forty-eight hours; more or less, according to the weather. Some affirm that they have had good cyder by turning it directly from the press, without any other caution than leaving room for the liquor to ferment in the hoghead, where it remains from first to last: but this method is liable to many hazards, and successful, where it has been so, only in favourable seasons. The gross lees are apt to rise on every considerable change of weather, and when they do, they set the cyder on the fret, which, should it do no worse, certainly robs it of its spirit, and, when over, leaves it flat and vapid. Besides, repeated experiments have proved, that sourness in all fermented liquors begins even at the lees, and therefore the more of them is left among the cyder, the more readily it will turn eager.

Here I must observe, that a most important precaution is too often overlooked by many of those who make cyder of winter fruits; for that a sufficient warmth of the air is as essential to ferment the rough juices of hard apples, as it is dangerous to suffer the heat to be too great in the fermenting of cyder made of summer fruits. If the weather is very cold when the hard apples are pressed, the help of fires should be recurred to; or if that has been neglected, or could not be conveniently used, it will be right to carry the cyder to a place warmed considerably by the sun for a short time, in the summer, and there to place it out of the immediate reach of the rays of the sun. The bung of the cask must be loosened, because there will arise a degree of fermentation, which will attenuate any viscosity not overcome by the first fermentation. Great care must be taken that this fermentation be not carried beyond the nice point of correcting the rough raw taste of the fruit: for if it goes farther, the liquor will either become vapid, or turn to vinegar. As soon as the desired point is obtained, the liquor should be racked off, especially if much feculence has sunk to the bottom, and it should then be carried down into the vault, where it may be preserved long in perfection.

The choice of proper vessels to keep the cyder in after it has fermented is very material; no liquor being so apt as this to take the taste or twang of cask. New vessels, tho' the wood be ever so well seasoned, generally give a disagreeable relish to all liquors, and will do so remarkably to cyder, unless due caution be used before hand. Frequent scalding with hot water, into which some handfuls of salt have been first thrown, or with water in which some of the pomice has been boiled, and washing afterwards with cyder, are the usual remedies against this evil, and seldom fail of removing it effectually. Of old casks, beer vessels are the worst; they always spoil cyder, as, in return, cyder casks infallibly spoil

beer. Canary and brandy casks do well, and all wine vessels tolerably; for, provided the tartar adhering to their sides be carefully scraped off, and they well scalded, there is no danger in using them. The best way of scalding them, is to boil a parcel of dried wormwood in water, and with that and a brush of the same plant to rub and scour their insides. This will correct the acid of the tartar; and so will likewise all vegetable ashes used in the same manner. Those who advise fumigating the casks with brimstone, confidently affirm that the cyder becomes stronger, and keeps better, when the vessels have been thus prepared, and for this reason they tun immediately after the operation, and before the smoke evaporates. To enable such as may choose to examine, by fair trials, how far this is true in fact, I shall here add the neatest method of performance. Melt a pennyworth of brimstone, and dip in it a piece of new cloth, or of canvass, till all the brimstone is imbibed, and the cloth or canvass looks like a piece of searcloth: then roll it close, tie it, and with a wire suspend it at the bung, three parts in four within the vessel; light it, and let it burn till it is ready to fall into the cask, then take it out, and tun without delay. Some add a little powdered cinnamon, cloves, pepper, or other spice to the brimstone for fumigating, but I see no great reason for their so doing.

The best shaped vessels for keeping cyder in are, as advised by captain Syllas Taylor, in a letter subjoined to Mr. Evelyn's Pomona, and by Mr. Worlidge, those of which the barrel-boards are strait, the vessel broader at one end than the other, and standing on the lesser end, with the bung hole in the top. The advantage of this form is, that in the drawing of the cyder, though but slowly, the skin or cream contracted by its fermentation (as is the case of all strong liquors) descends, and covers the liquor by means of the tapering of the vessel, and thereby preserves to the last the spirits of the cyder, which would otherwise evaporate and waste. A little wheaten-bran cast in after the fermentation, thickens this coat or cream of the liquor, and thereby conduces much to its preservation.

We come now to a point of great importance, and hitherto of as great uncertainty, which has raised among the curious a controversy of long standing, and not likely to be brought to a speedy decision, without a course of regular experiments. Some maintain that continued fermentation and frequent racking, certainly spoil the cyder; whilst others assert, that it can never be good without them. Some rack once, some twice, and others whenever the liquor frets. Some look upon the lees as the food and nourishment of cyder; others as a cause at hand, upon every change of weather, to set it on the fret, and turn it sour. Every man has a system of his own, and a peculiar practice consequent thereon; and so great is the variety of methods, that nothing certain can be drawn from them but this one general conclusion, that we are still at guess work, and must be obliged to future trials for any rules that can be thoroughly depended on. I shall therefore here relate the several ways now in use, and then give my own general opinion of this matter; but I strongly recommend the making of accurate experiments on each.

One method is, to leave the cyder in the vats some days longer than was before advised, and till it fines in a greater measure: then to tun it into hogheads, where it is to remain without any farther racking. Those who recommend this practice say, that their cyder is thereby rendered the stronger and mellow: and those who object to it reply, that lying on the grosser lees, which cannot all be fallen in the vats, it must be apt to fret, turn sour, and, in unsettled weather, eager.

A second and more common method is, a fortnight after tunning, to rack into other hogheads. There the cyder undergoes a second gentle fermentation, and while this lasts, the bung must be left open; afterwards, when the fermentation lessens, covered only with a wet cloth, or a tile; and when it is quite over, stopped down close with well tempered clay, kept moist to prevent its cracking, by strewing over it a handful of bay-salt.

To this second racking others add a third in March or April, when the lees have thoroughly subsided. This again is followed by a little fermentation, and for that reason chiefly it is objected to by those who think every fermentation hurtful which is not strictly necessary.

Others, on the contrary, and particularly those of Devonshire, where the strongest cyders are made, look upon a thorough fermentation as the great secret to have their cyder fine, light, and free from dregs, and accordingly they not

only approve of the above last mentioned method, but proceed much farther, as follows :

At first running they do not fill their hogheads to the bung, but leave an empty space to receive a pailful of fresh cyder from the press : this renews or increases the fermentation, and sets the whole on working with some violence. The froth which rises at the bung is carefully skimmed off, and the waste of liquor thus occasioned is constantly replenished with unfermented cyder. By these means the whole is kept from the fret for a considerable time : for it is not uncommon to have cyder thus managed working for a fortnight. A month after this operation, and the stopping of the vessels, the cyder is racked, and, generally speaking, in two months more, a second time : and if it frets, which however is said seldom to happen in this method, it is racked off a third and a fourth time.

To make a proper choice among the several above recited methods, they should be tried together, with the same fruit of equal ripeness ; the cyders should be kept to the same age, and their different qualities should be attentively observed. Just information cannot be obtained in any other way : for the want of accuracy and exactness will render the experiment fruitless and insignificant. Every one will tell you, that his method affords good cyder : but this general expression gives no determinate idea, and forwards knowledge very little. Would gentlemen be at the trouble to keep notes, and minute down all the differences observable in the same cyders under different managements, it might soon be known what method gives the strongest, which the neatest, the roughest, mellowest, or lightest cyders : and every one might then pursue, as his taste or interest should direct, that which would answer best : but till something of this kind be done, only very slow and inconsiderable improvements can be expected.

In the mean time I must observe, in general, that whenever the lees of cyder are in such quantity as that the liquor cannot preserve them from a tendency to putrefaction, as must be the case with the first, and generally the second lees, it is certainly advisable to rack off the liquor ; and that, if the cyder is kept in a place not subject to the various changes of the weather, the little fermentations raised by racking cannot be attended with any great danger, nor will the frettings return. But as to the frequently repeated fermentations which are said to be, of choice, the practice of the makers of cyder in Devonshire, they surely are by no means advisable.

The few points which experience has hitherto determined in regard to the making of cyder are, that weak cyder cannot bear above one or two rackings without too great a loss of spirits ; that strong cyder made of winter apples will stand several rackings, and thereby grow mellow, and be the sooner fit for drinking ; that the more the liquor is fermented, the rougher it will grow ; that fermentation is no other way so well promoted, as by putting into the hoghead, from time to time, some of the liquor fresh drawn from the press : and lastly, that to have a rich, racy, palatable cyder, a little inclining to the sweet, great care must be taken to prevent all future fermentation after the liquor is once become fine. If it should be foul, isinglass will help to fine it, by precipitating the flying lees.

In general, the cyder that is longest in fining is the strongest and most lasting, if it has been made of thoroughly ripe fruit : but, as was before observed in the article of wines, all liquors will be much longer in clearing in mild moist weather, than in cold dry weather, or frost.

When the bung-hole of the vessel is closed up, a small vent-hole should be left open, or but loosely stopped with a peg, for several days, till the wild spirit of the liquor be spent ; for otherwise it will break the cask, or find some other vent, which, though but small, will always abide open, and prove the ruin of the cyder. Many have spoiled their cyder by this only neglect, and never apprehended the cause thereof. After this wild spirit is spent, the vent-hole, as well as the bung, should be stopped quite close ; and then the cyder, though seemingly flatish at first, will soon improve, and become brisk and pleasant.

Deadness or flatness in cyder, if occasioned by a too free admission of air into the vessel, for want of right stopping is remedied by grinding a small parcel of apples, and putting them into the cask, which should then be stopped up close : but care must also be taken to open the vent sometimes, or the vessel will be in danger of bursting. The liquor thus managed must likewise be drawn off in a few

days, either into bottles, or into another cask, lest the muck should corrupt the whole mass ; to prevent which some put in only the juice of the newly pressed apples. The same may be done to flat bottled cyder, by adding about a spoonful or two of new must to each bottle of the dead liquor, and stopping it again. Cyder that is dead or flat will often revive again of itself, if closely stopped, upon the revolution of the year, and the approach of summer : but cyder which has acquired a deadness or flatness by being kept in a beer vessel, cannot be revived again.

Thick cyder may be rendered clear and good by a second fermentation, or sometimes by only throwing into it two or three quite mellow apples. But cyder in which the acetous fermentation has taken place, can never be restored. If it be only a little sourish, or drawn off in another vessel, about a gallon of wheat (blanched is best) to a hoghead of cyder, and so in proportion for any other quantity, will both amend and preserve it : or if it is so sour that the wheat does not answer that purpose, it may be corrected by egg shells, powdered alabaster, &c.

Cyder which has contracted any ill flavour or taste from the vessel, or from any other cause, will be helped by the addition of a little mustard seed ground with some of the cyder.

Ginger accelerates the maturation of cyder, gives it more brisk spirits, helps fermentation, promotes its duration, and corrects its windiness.

When the juice is too thin or weak, it is a common and very advisable practice to give by art that strength which nature had not bestowed. To this end, raisins of the sun, or the lees of rich wines, are used with good success ; as is also sugar. Writers on this subject give various directions for the use of this ingredient : but it would be needless to repeat them here, as it is of very little importance in what manner it be done, the giving a body to the liquor being the only thing wanting, and this a proper quantity of sugar will effect, in whatever shape it is used. When the design is to colour the cyder, the sugar is boiled till it becomes brown, and then put into the cask.

Mr. Marshall, in his Rural Economy of Gloucestershire, having paid particular attention to this subject, and given such useful information to those concerned in this article, it would be doing him and the public injustice to withhold it. He says, " To adapt the register of this art to the public eye, and to render it as clear, yet full, as the nature of it requires, it will be necessary to describe, distinctly and minutely, its several stages. And previous to this detail of the art itself, it will be proper to take a view of its requisite apparatus.

" A mill house, on an orchard farm, is as necessary as a barn. It is generally one end of an out building : or, perhaps, an open shed, under which straw or small implements are occasionally laid up.

" The smallest dimensions, to render it any way convenient, are twenty-four feet by twenty ; with a floor thrown over it, at seven feet high ; with a door in the middle of the front, and a window opposite ; with the mill on one side, the press on the other side, of the window ; as much room being left in front, towards the door, for fruit and utensils, as the nature of the mill and the press will allow.

" The mill consists of a stone wheel, provincially a runner, somewhat in the shape of a corn millstone, running on its edge in a circular stone-trough, provincially, the chace.

" The size of the runner varies from two and a half to four and a half feet diameter, and from nine to twelve inches in thickness ; which, in general, is even like that of a grindstone : nor varying like that of a millstone : the weight one or two tons.

" The bottom of the chace is somewhat wider than the runner, that this may run freely. The inner side rises perpendicularly, but the outer side spreads, so as to make the top of the trough some six or eight inches wider than the bottom ; to give freedom to the runner, and room to scatter in the fruit, stir it up while grinding, and take out the ground matter. The depth nine or ten inches.

" The outer rim of the trough is three or four inches wide and the diameter of the inner circle, which the trough circumscribes, from four and a half to five feet ; according to the size of the mill.

" This is sometimes raised by a table of thick plant fixed upon the stone ; with a curb of wood, lessening to an angle fixed upon the circumference of the trough ; making the whole depth of the trough about equal to its width at the

bottom. This lessens the quantity of the stone ; and the plank upon the center answers a purpose hereafter to be noticed.

" The entire bed of a middle sized mill is about nine feet, some ten, and some few twelve feet diameter : the whole being composed of two, three, or four stones, cramped together as one ; and worked, or at least finished, after they are cramped together.

" The best stones are raised in the forest of Dean. They are mostly a dark reddish grit-stone (non-calcareous), working with sufficient freedom, yet sufficiently hard, for this intention. The bed of the mill is formed, and the trough partly hollowed, at the quarry ; leaving a few inches at the edge of each stone, uncut out, as a bond to prevent its breaking in carriage. Much depends on the quality of the stone. It ought not to be calcareous, in whole or in part, as the acid of the liquor would corrode it. Some of the Herefordshire stones have calcareous pebbles in them, which being of course dissolved, leave holes in the stone. Nor should it be such as will communicate a disagreeable tinge to the liquor. A clean-grained grindstone girt is the fittest for this purpose.

" The runner is moved by means of an axle passing through the center ; with a long arm, reaching without the bed of the mill, for a horse to draw by ; and with a short one passing to an upright swivel, turning upon a pivot, in the center of the stone ; and steadied at the top, by entering a bearing of the floor, above. An iron bolt, with a large head, passes through an eye, in the lower part of the swivel, into the end of the inner arm of the axis. Thus the requisite double motion is obtained, and the stone kept perfectly upright (which it ought to be) with great simplicity, and without stress to any part of the machine.

" This is the ordinary method of hanging the runner. There is a more complex way of doing it ; but I see no advantage arising from it. There are some few mills, it seems, with two runners, one opposite the other.

" On the inner arm of the axis, about a foot from the runner, is fixed (or ought to be, though it is frequently wanting) a cogged wheel working in a circle of cogs, fixed upon the bed of the mill. Their diameter of the wheel is determined by the height of the axis above the bed of the mill. The diameter of the ring of cogs, by the distance of the wheel from the center of motion. The use of these wheels is to prevent the runner from sliding ; to which it is liable, when the mill is full ; the matter, when nearly ground, rising up in a body before the stone. Besides, by assisting the rotatory motion of the stone, it renders the work more easy to the horse. These wheels require to be made with great exactness ; and in a country, where carpenters are unaccustomed to them, a mill-wright should be employed in fixing them.

" The situation of the mill is such as to leave a horse path, about three feet wide, between the bed and the walls ; so that a moderate-sized mill, with its horse path, takes up a space of fourteen or fifteen feet every way.

" The press is situated, as near the horse path, as convenience will allow, for the more easy conveyance of the ground materials, from the mill to the press.

" The principle of the press is that of the packing press and the common napkin press ; a skrew working within a square frame.

" The sizes of presses are various. The bed, or bottom, is about five feet square, of strong plank, or of stone, placed on sleepers, about a foot from the ground floor ; or raised on mason's work, to two or three feet high. On each side rises a strong upright cheek, provincially a sifter ; and across the top (the upper surface level with the chamber floor) lies a nut, or dimensions suitable to the size of the skrew, which is usually about ten inches in diameter. The foot of the skrew is square, with cross holes for inserting a lever ; or has a wheel fixed round it for that purpose. A sinker, provincially the bridge, is hung beneath it, and steadied by the cheeks, in the usual manner.

" The bed or floor of the press, which is now composed entirely of wood, or of stones, not of lead, has a channel cut a few inches within its outer edge, to catch the liquor as it is expressed, and convey it to a lip, formed by a projection on that side of the bed opposite to the mill ; under which lip a stone trough, or wooden vessel, is sunk within the ground (when the bed is fixed low), to receive it.

" The press is worked with levers of different lengths ; first, a short one ; next, one of a moderate size, by hand ;

and lastly, with a strong bar, eight or nine feet long, by means of a species of capstone, provincially a windlass ; an upright post, about six inches in diameter, with a pike or pivot at either end ; one of them being inserted in the ground floor, the other in a bearing of the chamber. From the upper part of this post passes a very strong rope, with an eye at the end to receive the end of the bar ; which has a cross pin, or a shoulder, a few inches from the end, to prevent the rope from slipping. In the lower part of the post, about three feet from the ground, is one or more holes, for a lever or levers. By these means an excessive purchase is obtained.

" The utensils belonging to a mill-house are few : the fruit is brought in carts or baskets, and the liquor carried out in pails. The haircloths, which will be mentioned, are the principal addition to the mill and press.

" The expence of fitting up a cyder-mill-house depends on the size and quality of the mill and press. One of a moderate size, for a farm, may be furnished, completely, for twenty to twenty-five pounds. One, on a small scale, might be furnished for ten to fifteen pounds : much depending on the distance of carriage of the stone.

" This expence is usually borne by the landlord.

" A mill-house substantially fitted up, will last many years. I have observed a mill and press which, by the date upon them, have been set up more than twenty years ; yet they appear almost as fresh as new. Many of the old mills and presses, which are seen, may, compared with these, seem to be a century old ; or, the mills, more particularly, a greater age ; and are probably the original mills of the farms they are upon.

" The general subject naturally separates into the following principal parts :

" The fruit and its management—grinding, and the management of the ground fruit—pressing, and the management of the residue—fermenting—correcting—laying up—bottling.

" of fruit, the particulars to be attended to in this first stage of the art, are,

" The time of gathering, the method of gathering, maturing the fruit, preparing it for the mill, and mixing different sorts for liquor.

" Time of gathering is varied by the season and the sort of fruit. The early pears are fit for the mill, in September. This year (1789) there was not, in the middle of October, a quash spear left in the country for a specimen.

" But there are few apples ready for gathering, provincially picking, before Michaelmas ; though the winds sometimes throw them down, in quantity, before that time. And this year, the drink houses having long been dry, apples were gathered by the time they were fully grown. Many trees were stripped, and their produce made into cyder and drank, before Michaelmas.

" For sale cyder, however, and for keeping drink, they are suffered to hang upon the trees, until they be fully ripe. This year, (a forward season), Herefordshire was in the height of fruit picking, the latter end of October. In the Vale of Gloucester, the store apple, a somewhat early fruit, was much of it shook down, by the high winds of September ; and many orchards were cleared of them before Michaelmas. But the middle of October, in a common season, esteemed the time of gathering the store apple.

" The criterion of a due degree of ripeness, is that of the fruit's falling spontaneously from the tree. Nature is the best judge of this crisis. No art has yet been discovered to mature unripe fruit, in any way equal to nature's process. Fruit, in all human probability, does not quit the tree (in an undisturbed state) until it has received its full complement of nourishment. But having obtained this (or presently afterward) it is probable, that the fruits, under consideration, are suffered to disengage themselves by their own specific gravity : consequently, to force them away, before that period, is defrauding them, in all human probability, of their most valuable particles.

" The harvesting of fruit is widely different, in this respect, from the harvesting of grain ; which has the intire plant to feed it, after its separation from the soil ; while fruit, after it is severed from the tree, is cut off from all possibility of a further supply of nourishment ; and although it may have reached its wonted size, some of its more essential particles are, it is abundantly evident, left behind in the tree.

" Some of the later-ripe fruits, however, will hang on, until they be in danger of being caught in the frosts ; which, if

if severe and lasting, injure materially for the purpose of liquor. In the great fruitage of 1784, a very considerable part of the best fruits were in a manner lost by the frosts. The buyers of sale liquors fixed their price for cyder so very low, that the farmers obstinately suffered the apples to be frozen on the trees, or in heaps if collected, rather than accept of the price they were offered. The consequence proved disadvantageous to the buyers, as well as the farmers; they being afterwards obliged to nearly double the price, to those who had worked their fruit, or had saved it from the frost.

"The ordinary method of gathering which I have seen used, and which is, I believe, the prevailing practice of the country, is to send men with long slender poles or rods, provincially polting lugs, to beat the trees; and women, with baskets, to pick up the fruit. I have seen two men and eight women, thus employed, as a set; with an ox wain, and a boy to drive it, receive the apples as they were collected; clearing the trees as they went.

"But this is contrary to the foregoing principles. The apples of the same tree differ, perhaps many days, perhaps some weeks, in their times of ripening; owing to aspect-exposure, and perhaps other causes which we are unacquainted with. Consequently, some part of the natural richness and flavor of the fruit is cut off so effectually, that no art can retrieve it: brown sugar and brandy are but mean substitutes.

"Nor may the loss of the richness, strength, flavor and colour, which are left behind in the tree, be the only evil of the ordinary method of gathering fruit for cyder. Every thing depends on the vinous fermentation, which the liquor has to pass through. If this be interrupted, or rendered complex, by a mixture of ripe and unripe fruits, and the liquor be not in the first instance sufficiently purged from its feculencies, it may be difficult, afterward, to effect the purgation, without injury to the liquor. Brimstone and bullock's blood may alleviate, but cannot altogether remedy the evil.

"Some few men, on these principles, or in pursuance of the dictates of their own experience, go over their fruit trees twice: once, when the spontaneous fall begins to take place, with a hook, leaving such of the fruit to mature, as will not quit the boughs, with a gentle agitation. And a second time, when those are sufficiently ripened, or winter is likely to set in, with the polting lugs; finally clearing the trees.

"If art may, with propriety, be used, in this stage of the business, these appear to be the most rational means of applying it.

"By way of correcting the crudity of the unripe fruit, which in the common practice has been forced from the trees, in the way that has been mentioned, the whole is laid together in large heaps, in the open air, exposed to the weather, until the ripest, that is to say the richest and finest of the fruit, is beginning to rot. Thus destroying by an injudicious application of art, the natural perfection of the whole.

"Such, at least, is the ordinary management of fruit; under which management three-fourths, or perhaps a much greater proportion of the cyder produced in the district is made.

"There are men, however, aware of the impropriety of the practice; but they differ in their ideas on the means of rectifying it. One is of opinion, that the ripe fruit, having dropped spontaneously, or having been shook down by a gentle agitation of the boughs, should lie ten days under the trees, as it falls; and then be gathered, and carried immediately to the mill; without any further maturation. And, in pursuance of this idea, some few orchards, and even cultivated grounds, are seen with fruit lying under the trees, so thick, that the foot could not well be set down among it.

"Others object to this practice; as exposing the fruit; not only to pigs and other live stock; but to the weather: alledging that rain and dews are injurious to fruit after it has quitted the trees.

"Their opinion is, that it ought to drop ripe from the tree: to be picked up while dry; and to be kept dry, under cover, some time afterwards to mature; and, some will have it, to take a degree of heat: while others object violently against its heating; consequently against lofts; thinking, that it cannot be kept too cool, in the open air; and that rain water is not injurious to it.

"Reason and common sense, however, object to this. All vegetable substances, after they are severed from the soil,

lose their flavor, at least, in being exposed to the weather. With regard to this, apples, as hay and corn, ought, no doubt, to be harvested dry.

"Upon the whole, we may conclude, that, in strictness of management, fruit ought to drop spontaneously from the tree; to be collected while perfectly dry; and to be laid up, under cover, spread abroad of such a thickness as to prevent any injurious degree of heat. It is the opinion of those, who are best able to judge of this matter, and whose practice accord with their opinion, that, in a room, fruit ought not to lie more than ten inches thick; and that in a fruit-loft a thorough air should be preserved.

"Every mill house should have a fruit camber over it; with a trap door to lower the fruit down into the mill house. Or there may be a valve over the bed of the mill, furnished with a cloth spout or tunnel, reaching down to the chace; in which the fruit may, of course, be scattered at pleasure.

"No straw is used in the lofts. Sometimes the fruit is turned. But this, I believe, is not a common practice.

"The due degree of maturation of fruit for liquor is however, a subject, about which men, even in every district, differ much in their ideas. The prevailing practice (as has been intimated) is to let it lie in heaps, until the ripest begin to rot, or are actually rotten. But this is wasting the best of the fruit; and is by no means an accurate criterion. Some shake the fruit and judge by the rattling of the kernels: others cut it through the middle and judge by their blackness. But none of these appear to be a proper test. It is not the state of the kernels, but of the flesh; not of a few individuals, but of the major part of the prime fruit; which renders the collective body fit or unfit to be sent to mill. It is true, a few individuals, or the kernels of the middle-ripe fruit may be some guide to the state of the flesh of the majority; but why consult a criterion when the subject itself is present? The most rational test of the ripeness of fruit, which I have met with, is that of the flesh having acquired such a degree of mellowness, its texture such a degree of tenderness, as to yield to moderate pressure. Thus when the knuckle, or the end of the thumb can, with moderate exertion, be forced into the pulp of the fruit, it is deemed in a fit state for grinding. Or, in less practical terms, the proper state of maturation is when the flesh has acquired its highest degree of richness, and the kernels their highest degree of flavor; and while the rind yet retains its brightness and pungency.

"But although the right management of the fruit may appear to be pretty accurately understood; and not difficult to be executed; yet in practice, ripe and unripe fruit are not to be kept separate so easily as theory may suggest. It is tedious to wait the ripening of every apple, and to collect every apple as it drops. Besides, high winds do not always make the requisite distinction: the unripe and those which are sufficiently matured for gathering, are frequently thrown down together: and if the hook be used, the effect is in some degree similar.

"In practice, therefore, there is only one method of avoiding a mixture of fruit: that of separating it by hand; either when it is laid up, or at the time of sending it to the mill. And it is more than probable, that this is one of the grand secrets of cyder-making; by which those who excel in the art are monopolizing the credit of it. It is matter of astonishment, however, seeing the obviousness of its utility, that it should not long ago have been adopted in common practice.

"Some extra trouble and expence is, no doubt, incurred by this practice. But there is no department of manufacture, which is not attended with trouble and expence. If the *ware* pay tenfold for it, the expence vanishes, and the trouble becomes a pleasurable employment. In the infancy of the woolen manufacture, for instance, it is probable the entire fleece was carded, spun, and woven together. But now the sorting of wool is become an employment of no small importance. And were the sorting of apples for cyder, once to become the established practice, farmers would as soon think of sowing wheat and vetches together, as of grinding unripe, ripe, and rotten fruit together in the cyder mill. Yet all the preparation, which the apples receive in common practice, at present, is that of picking out the black rotten, which is generally known to give the liquor a disagreeable flavor: and, even this work, I understand, is frequently done in a very imperfect manner.

"There are however, some few individuals, who pay attention to this department of the art. In the practice of

one man ; a dealer, who manufactures his own liquor ; more especially fire cyder ; and whose liquors are a proof of the excellency of his practice ; I found the brown as well as the black rotten carefully picked out : even if part of an apple be tainted, the faulty part is cut out ; the sound part only being suffered to go into the mill. And in that of another superior manager, whose practice may be said to be nearly perfect, not only the rotten, but the crabbed, that is, the small crude under-ripe fruit, are picked out, and thrown aside for family drink ; thus selecting the prime fruit, in a proper state of maturation, to be ground, alone, for liquor of the first quality.

" In the ordinary practice, no studied composition or selection of sorts is made. The different kinds are mixed, indiscriminately, or without any other distinction than that of keeping the early and the late fruits separate, and the old fruits distinct. A judicious assortment of fruits is, however, spoken of as highly beneficial to liquor ; but I have met with nothing, in practice, that establishes the position : and it is a well established fact, that the finer liquors are made from select fruits. Nevertheless, it is more than probable, that the liquor of ordinary fruits may be improved by a judicious mixture ; and, to those who have much ordinary fruit in their plantations, a proper mixture of it may be an object of attention. A person, in Herefordshire, is mentioned as an adept in the art of commixing : not fruit, however, but liquors which have been separately drawn, and while they are under the process of fermentation : while others are said to mix the liquors, according to their flavors, after they are manufactured. But these by way of hints.

" In the business of grinding, the cyderists of this district are far superior to those of the southern countries ; where, as has been said, a kind of cyder is sometimes made ; but where the mill not unfrequently consist of a wooden roller, stuck with hobnails, working against an upright slab, beset in a similar manner. With this petty machine, the apples are broken, or torn, into fragments, that the press may have fuller power over the juice, than it would have, if the fruit were placed in it whole. For there, and every where, I believe, except in what are called the cyder countries, it is generally considered, that the cellular juice of the pulp, only, is the requisite ingredient of good cyder.

" In this country, however, it seems to be generally understood, that cyder made from the juice of the pulp alone, is far from being perfect ; as wanting, in a great measure, one of its most valuable properties, flavor, and some will say colour : it being likewise, I believe, pretty generally understood, that the finer cyders owe their superior flavor to the kernels, and their colour to the rind.

" The Hagloe crab, however, is an evidence against this idea. It is one of the palest-rinded apples, which grow ; yet produces the highest-coloured cyder, which is made. The fire apple is likewise pale-rinded ; yet affords a high-coloured liquor. Some are of opinion, that the rind gives the strength. Others, that it communicates flavor to the liquor. From a slight examination of the rinds of fruit, they appear to be warm and aromatic ; qualities belonging to essential oil ; and it is probable, the pungency may pass at strength ; while the aroma may communicate additional flavor.

" Hence, in grinding, it becomes requisite to common good management, that the rind and the kernels, as well as the pulp, should be crushed or broken in such a manner, as to enable them to impart their qualities, with greater freedom to the liquor.

" The effect of the stalks of fruit has not, perhaps, been attended to. Attentive managers pick the largest off, in sorting the fruit ; but not, perhaps, with sufficient scrupulousness. The stalks of raisins are known, I believe, to have a bad effect on the wine made from that fruit, and those of apples may have a similar effect on cyder.

" In this intention, the stone runner and chace are much preferable to the petty contrivance mentioned above ; but they are not, in their present form, and under ordinary management, by any means equal to the entire reduction of the fruit. I have never seen any ground fruit go to the press (except in one instance) without having a large proportion of unreduced fragments of fruit among it : whereas, on the principles, which are here adopted, the whole ought to be reduced to a state of mucilage or pap. Nor have I yet seen any residuum come from the press, without a very large proportion of the kernels unbroken : whereas, on the principles received, every kernel should be crushed.

" Having observed the simplicity, and high degree of per-

fectness, with which the sugar-mills grind the canes, or rather press out their juice, between two plain iron rollers, the imperfections of the cyder mill may appear the more striking.

" But the sugar-cane is a long fibrous body, and readily passes through between the rollers ; whereas fruit, being globular, and of a cellular substance, is not easily laid hold of, or if caught, has no lengthened fibres to induce it to pass, like the cane, between plain rollers.

" It has, however, been found, that between fluted rollers it may be made to pass ; and, in consequence, these rollers are in use, though not common. They are of cast iron, hollow, about nine inches diameter, with flutes or teeth, about an inch wide, and nearly as much deep. In general, they are worked by hand, two men working against each other. Between these the fruit passes twice : the rollers being first set wide, to break it into fragments ; and afterwards closer, to reduce the fragments. But even this is not a perfect engine : in the residuum from the press, many kernels are found. Besides the acid of the fruit is liable to corrode the iron ; and this, in return, to tinge the liquor ; though neither of these inconveniences are acknowledged. In a country, however, where stone is not easily to be had, this may, perhaps be found the most eligible cyder-mill.

" But in this district where stone is sufficiently plentiful, the stone-runner and trough seem to be the most eligible mill at present known ; though it appears to me highly probable, that, with attention and perseverance, a more perfect machine might be invented.

" Be this as it may, however, the present mill appears to be capable of improvement.

" It is, at present, an unfinished machine : I mean when it is first turned out of the workman's hands ; time and constant wear, does that, in part at least, which the workman leaves undone.

" The acting parts of the machine ; those which are to bruise the rind, and crush the kernels, are the face of the roller and the bottom of the trough. But instead of their being adapted to each other, in such a manner as to effect these purposes with a degree of certainty, they are left in such a rough unfinished state, as in a great measure prevents them during the first fifty years at least, from performing that, which is their principal intention. Instead of being worked over, and fitted nicely to each other, with the square and chisel, they are hewn over with the stone-mason's peck only ; leaving holes and protuberances, which would save even horse beans from the pressure ; much more the kernels of fruit. A runner which has been worn two and twenty years, has holes left in it, which would lodge half a dozen kernels with safety.

" To account for this absurdity seems impossible. Perhaps the roughness was intended to prevent the runner from sliding ; but the use of the cogged wheels has superseded this intention. Perhaps it was left to gather up the fruits with greater effect ; but, surely, deep chisel marks, left in the form of flutes across the face, would have answered this purpose better ; and would, perhaps, have laid hold of, and fixed the kernels, so as to secure their being effectually broken, preferable to any other expedient equally simple. Or, perhaps, the custom was established, when the uses of the rind and kernel were not known ; and time has not yet corrected the error.

" I have been told that the roughness is left to cut the fruit the faster on its being first put into the trough ; and that on this ingenious principle, some will peck their runners over, so often as they were smooth. To such cyder-makers I would recommend the hobnail mill, which would come much cheaper, rid work still faster, and save the expence of pecking.

" Be the origin of folly what it may, it is painful to observe its effect. In this case, however, the folly, and, of course, its effect, may be easily removed. Having made the face of the roller as true as the square and the chisel can render it, work the bottom of the trough to it ; until not a mustard seed can escape them. The kernels of fruit are hard, slippery, and singularly difficult to fix : escaping pressure in a peculiar manner, and with singular alertness.

" Another improvement of the common cyder-mill appears to be much wanted : namely, a method of preventing the materials, in the last stage of grinding, from rising before the runner. And, another, a more mechanical way of stirring up, and adjusting them in the chace.

" Until these improvements be made, cyder-mills must remain, what most of them evidently are, at present, imperfect machines.

"The method of grinding is to scatter in the whole quantity to be ground together, at once: or, to ease the horse, at twice; observing to put in the whole before any of it be stirred. A woman, or more frequently a girl, drives the horse, and stirs up the fruit as it is ground, and beats down what lodges on the sides of the trough, with a large wooden spatula, somewhat in the form of a cricket bat: continuing until the whole be deemed sufficiently ground.

"The quantity ground at each mill-full varies very much; even in mills of the same size. A bag, about four corn bushels, is, I believe, the most usual quantity; for a middle-sized mill: but much more than that quantity is sometimes ground at once; and, in one instance, I observed only half that quantity was ground together, in a mill of the middle size. From the observations I have made respecting this operation, it appears a great error to grind too much at once. In the instance, in which half a bag, only, was ground, the work seemed to go off quicker, and to be more effectually done, than when the trough is choaked with a greater quantity.

"The quantities ground in a day, by mills of the same size, varies still more.—A man, who has two or three hundred hogsheds of liquor to make, is too anxious to get his work forward, to pay due attention to grinding his fruit; there has been instances of five or six hogsheds of perry being made in one day (working early and late:) but three hogsheds of perry, or two of cyder, is, I believe, the medium day's work. While some few men, who know the value of grinding effectually, never suffer more to be made than one hoghead of cyder a day: reducing as nearly as the present mill is capable of reducing, the entire substance of the fruit to a uniform pap or mucilage.

"From what goes before, it appears, that men, in general, have pretty accurate ideas of the manner in which fruit ought to be ground: though, through a want of leisure, or a want of industry, and, through the present imperfection of the mill, few men approach them in practice: but with respect to the management of the reduced materials—provincially the *must*. This term is, here, somewhat unfortunately applied. Must, in its accepted sense in the English language, signifies new liquor unfermented, whether from the wine press, the cyder press, the mash vat; but, here, it seems to stand for every thing else belonging to cyder making. The ground fruit, before it goes to the press, is called must; though from some expressions, in use, it should seem to mean only the fibres or indissoluble parts, which are mixed among the liquor; and the residuum, after pressing, is also termed must. The term, on its first introduction, has evidently been misapplied. I shall, therefore, to avoid confusion, lay it entirely aside. In Surry, the reduced fruit is called pomage, an apt term for it: pom-mash would be still more applicable.

"They are, in general, so far from the line of rectitude, that one would imagine their faint efforts, at reducing the rind and kernel, were made in compliance with custom, rather than on the principle of giving their cyder flavour, colour, or any other valuable quality; for, in common practice, the pomage is pressed immediately as it is ground (even though four or five hogsheds a day are made). No sooner is it out of the mill than it is into the press.

"By this conduct, the rind and kernel, let their powers be what they may, have no time to communicate their qualities to the liquor. They are not, like the flesh of the apple, tender cellular pulp; but fibrous and vascular substances; imparting their qualities less freely than the pulp; requiring the formal process of extraction before they part with them wholly. It would be equally reasonable to expect that the whole virtue of hops might be extracted by pouring the wort through them in a sieve, as to expect that the whole of the virtues of the rind and kernels of fruit can be extracted in a few minutes.

"This appears so evidently in theory, that it is no wonder men of reflection, and who wish to excel in the art, should let their liquor lie upon the must twenty-four hours, or a longer time; or that others, more fully impressed with this idea, should, after the pomage has lain, in open casks, twenty four hours or a longer time, re-grind it.

"By this means (supposing the mill to be perfect) the kernels, which were broken in the former grinding, being now no longer rigid untractable substances, are reduced to particles of the smallest size; and are, of course, no longer able to withhold their virtue from the liquor. Consequently, by these means, the entire apple is given to the cyder;

and (supposing the mill to be perfect) every thing done; which art, perhaps, can do, with respect to the grinding and management of the reduced fruit; previous to the pressing.

"Formerly the pomage was packed up; in a pile; on the bed of the press, in straw, layer between layer. But at present, hair cloths are commonly used in forming the pile—provincially the cheese—to be pressed.

"These cloths are made of common hair-cloth; such as is used, or was formerly used, in covering malt-kilns. The texture loose, frequently, perhaps, too loose to be perfect in their intention. The usual size about four feet square.

"The method of forming the pile varies. In Gloucestershire, a wooden rim, frame, mould, or gauge;—about three feet square, and four or five inches deep;—is generally used in making the cheese, (a term somewhat awkwardly borrowed from the dairy). In this case, the gauge is set, with great exactness, every way in the center of the press; a cloth spread evenly over it; and the pomage laded into it, with a large wooden dish or other utensil. A sufficient quantity being thrown in to form a layer; from two to three inches thick, it is spread evenly with the hands, and worked truly against the sides and into the corners of the mould; the skirts of the cloth laid over smooth, and folded neatly at the corners; a fresh cloth spread on; and filled in a similar manner: first raising the gauge a few inches; so that its upper edge may be level with the cloth when filled. Thus continuing to raise the moulds and fill the cloths, until ten or twelve cloths are filled, and the pile is, of course, raised from two to three feet high.

"The height of the pile when finished, however, depends much on the state of the pomage: for, as the pile rises, the superstructure acts as a press to the substrata; so that a considerable proportion of the juice of pears, or of apples which afford much, escapes during the operation.

"The pile being raised to the desired height, and the top made smooth and perfectly level; a broad, square leaf, of strong boards, framed firmly together, somewhat larger than the top of the pile, is placed upon it; and upon this, logs, or blocks, two-and-two across, are piled; until they reach the bridge; the base of the screw being previously wound up to the nut; for a purpose which will be mentioned.

"In Herefordshire, I observed, in several instances, a different mode of forming the pile. In this method, no gauge is used; the whole being done by the eye; nor is the pile carried up either plumb, or square. The corners are cut off; (for the greater convenience; I suppose, of securing the corners of the cloths) and the dimension of every layer is lessened as the pile rises; so that when finished, instead of being a cube, or nearly so, as in the first mentioned practice, it forms the lower frustum of a pyramid; being somewhat considerably wider at the bottom than the top.

"This, however, appears to my mind an improper form. All fluids endeavour to escape pressure: If it be applied in the perpendicular direction, they endeavour to fly out horizontally. Thus the pomage (a subfluid) is forced toward the outward edges of the cloths; which, in this form of the pile, have no immediate pressure: an indirect horizontal pressure, arising from the natural law of fluids; being all the compression which the outer sides of the pile receive.

"The method of applying the power of the press has been described. It is generally worked by one man; who, with the girl that attends the mill, and a man to fetch in the fruit, and carry away the liquor as the reservoir under the lip of the press fills, make a set, for the mill-house.

"The pressing is done leisurely, that the liquor may draw off the clearer; and to give the assistant time to keep the reservoir free. The first runnings come off foul and muddy; but the last, especially of perry, will be as clear, and as fine, as if filtered through paper: a sweet palatable beverage.

"In giving the last pinch of the press, with the purchase-roller, the man, or men, if more than one be employed, stoop under the rope: hence the use of raising the foot of the screw as high as may be, before the operation commences; and hence the use of raising the bed of the press; by which means fewer blocks are wanted; and a more convenient receptacle for the juice obtained.

"By encreasing the number of hands to three or four, the residuum may be reduced to almost any degree of dryness.

ness. Hence the cyder-press might be styled a most perfect engine.

"In the common practice of the country, the first residue is either thrown aside as offal (though perhaps very imperfectly pressed) or is returned (designedly underpressed) to the mill, to be washed: that is, to be reground, with water, for family drink. When the plantations are large in proportion to the farm, a sufficient quantity of family liquor is obtained, in a plentiful year of fruit, from the washings of the residue, to last the year round, or a longer time; where the plantations are proportionally small, and in a scarce year, water is thrown into the mill, while the fruit is grinding, thus lowering the quality, and encreasing the quantity of the liquor. In harvest, it is customary to allow some malt liquor, or cyder of the best making.

"Thus throwing away, or applying to a mean purpose, what might, in familiar language, be termed the essence of fruit liquor. The juices of the rind and kernels, which, common sense would tell us, were we not told it by men of experience and observation, come off most plentifully with the last runnings; but it is allowed, however, by experienced managers, that the richest of the liquor comes off with the first runnings.

"Hence, men, who excell in the art, continue to press so long as a drop can be drawn; and, unsatisfied with this, return the first residue to the mill, to be reground; not with water, but with some of the first runnings of the liquor; moistening the materials to be ground as occasion requires.

"It is found, that even breaking the cakes of refuse with the hands, only, gives the press fresh power over it: for though it has been pressed to the last drop, a gallon or more of additional liquor may be got from a press full by this simple means. Regrinding them has a still greater effect.

"In this state of the materials, the mill gains a degree of power over the more rigid parts of the fruit, which, in the first grinding, it could not reach. If the face of the runner and the bottom of the trough were dressed with a broad chisel, and made true to each other in the manner which has been proposed, and a moderate quantity of residue were ground at once, scarcely a kernel could escape unbroken, or a drop of liquor remain undrawn.

"From the foregoing observations, it appears, first, that the fruit should be entirely reduced, before the whole of its virtues can be communicated to the liquor. There is, however, one inconveniency in grinding the fruit very fine: the substance, as well as the liquor, escapes the hair cloth, and fills the fermenting vessel unnecessarily; besides, perhaps, being injurious during the fermentation. But this effect may be remedied: I have seen an instance, in which the first runnings were poured through a hair sieve to catch part of their foulness: a piece of hair cloth thrown over the tun dish, would, perhaps, be still more effectual. The malt-liquor mash-tub is furnished with a hose, which stops a great part of the feculencies. The liquor, in that case, comes off almost clear; and, perhaps, fruit liquor ought to be rendered equally clear, before it be committed to fermentation. This degree of purity is obtainable, by suffering the foulness to subside, in the first cask, and drawing off the clear liquor, into a fresh vessel, previous to the commencement of the fermentation. By this means, the fermenting vessel, as well as the process of fermentation, may be freed at least from the grosser foulness. In some cases, by catching the critical time, and by filtering the lees in the manner which will be described, the must may be rendered almost perfectly clear.

"Secondly, that the reduced fruit ought to remain some time, between the grinding and the pressing, that the liquor may have an opportunity of forming an extract with rind and kernels. It is observable, however, that the best cyder, which the art, perhaps, has yet been able to produce, was made under different management. But it ought likewise to be observed, that the judicious manager of this cyder, grinds only one pressful (affording perhaps not quite an hoghead of liquor) a day; consequently the first-ground fruit, has most of the day to make the required extract; and every succeeding mill-full has a proportionate time: and although the liquor, under this management, proved excellent, yet had more of the bitter and fragrance of the kernels been communicated to it, it possibly might have been better. An objection to this practice is, that it hurts the colour of cyder; and the most experienced managers object to its lying more than twelve hours on the must.

"Thirdly, that the present imperfections of the mill are such as render it almost impossible to reduce the fruit, sufficiently, by a single grinding: but the juice, or a principal part of it, having been drawn off by the press, the residue is capable of receiving the requisite degree of reduction.

"Hence, upon the whole, the most eligible management, in this stage of the art, for those I mean who have leisure to pursue it, appears to be this: grind one pressful a day: press, and regrind the residuum in the evening. Infuse the reduced matter, all night, among part of the first runnings; and, in the morning, repress, while the next pressful is grinding.

"In this department of fermenting, the nicest judgment is requisite. The former are mere manual operations. The right principle being adopted, and a suitable apparatus being prepared, the execution requires no great share either of genius or experience. But in conducting the fermentation properly, much skill, and a close attention are requisite.

"In the prevailing practice of the district, the liquor is tunned; that is, put into hogheads or other casks; immediately from the press. The casks in the ordinary practice, being filled to the bung hole. Some judicious managers, however, object to the filling up of the casks; esteeming it more eligible management to leave them about a pailful ullage. While others, still more deeply versed, perhaps, in this mystery, leave an ullage in proportion to the ripeness of the fruit: thus, with liquor from under-ripe fruit the cask is filled; but with that from fruit which is more mature, an ullage is left, in proportion to the state of ripeness.

"With respect to the temperature of the air, in which fruit liquor ought to be fermented, nothing accurate, I believe, is to be learnt in this district. Even the professional dealers, I understand, are strangers to the use of the thermometer. It is, however, generally understood, that fermenting liquors should not be exposed to frost. Nevertheless it has been remarked, that frost, previous to the commencement of the fermentation, though it formed a sheet of ice on the surface, had no observable bad effect. But, in the commencement of the season, it is thought they cannot be kept too cool. In the middle of October, the air then about 60°, the casks were placed in sheds, or in airy buildings of the same, or nearly the same, temperature as the common atmosphere; and frequently in the open air. In this case the casks have a small piece of tile or flat stone set over the bung-hole, propped by a wooden pin in a leaning posture to shoot off rain water, &c.

"Later in the season, the casks are placed in close buildings; with windows, however, to admit occasionally a thorough air; which is generally thought to be salutary to fermenting liquors. I have, nevertheless, seen liquor of the most delicate kind fermenting in a close hovel, without a thorough air. In a complete manufactory of fruit liquor, the fermenting room should be under the same roof with the mill-house; a continuation of the press room; or at least opening into it: with windows or doors on every side; to give a free admission of air; and with suitable barricadoes to guard against severe frost; with fruit lotts over it; and, beneath it, a vault for laying up the liquors, after fermentation; with small holes in the crown of the arch, to admit a leathern pipe; for the purpose of conveying the liquors, occasionally, from one situation to the other. The dealer's warehouses are fitted up in a manner somewhat similar to this.

"No ferment whatever is made use of. I have not, at least, on repeated enquiry, met with one instance of any being used: even the most intelligent seem surprised at the enquiry. Let the species of fruit, the degree of ripeness, and the weather be what they may, the liquor is left to fight its way with its own weapons.

"Hence the commencement of the fermentation is entirely uncertain. Perhaps the first, perhaps the second, perhaps not until the third day, or perhaps in cold weather not until a week, or a month, after the liquor be tunned. It is observable, however, that liquor, which has been agitated in a carriage, though taken immediately from the press, will sometimes, on being laid down, pass, almost immediately, into the state of fermentation.

"The continuance of the vinous fermentation (or more accurately speaking the first stage of it) is not less uncertain than its commencement. Liquor, under the last mentioned circumstances, will pass through it, perhaps, the same day.

day. But less agitated liquors I believe, seldom go through it in less than two or three days; will sometimes continue under it five or six days.

"With regard to any criterion whereby to judge of the fermentation, as to its being perfect, imperfect, or inordinate, I have not been able to collect a single idea worth registering. It is a subject, to which most cyder-makers appear to have paid little or no attention; notwithstanding they are fully aware of the change, which takes place during its natural process; learning, from their own experience, that the liquor owes its intoxicating quality entirely to fermentation. It is true, the manufacturers of sweet cyder pay some attention to the fermentation: but their whole art appears to consist not in regulating it to any certain degree, but in checking it with every means in their power; preventing as much as they are able, any degree whatever of the vinous fermentation from taking place.

"It is observable that fermentation operates somewhat differently on different liquors. Thus, cyders made from fruits properly matured, generally throw up a gross spume, resembling that of malt liquor; forming, on the top, a brown crust, of a thickness proportioned to the species and ripeness of the fruit; the riper the fruit the more brown must is thrown up. Perries, on the contrary, throw up little spume, and seldom cover it with a brown crust; nevertheless, I have seen barland perry with a head resembling that of cyder; which, it is observable, is sometimes, like perries, unable to form a head; or is intentionally prevented from doing it, by management.

"Having remained some days in the first vessel, the liquor is drawn off the lees, and put into fresh casks: an operation termed racking.

"It appears to be fully and universally understood, that there is a critical time of racking, on which the future quality of the liquor very much depends. Hence, in the dealer's warehouses, persons are employed to sit up all night, to catch the critical minute. But what is rather extraordinary, men differ in their ideas with respect to the proper juncture. The prevailing idea seems to be, that the proper time to rack is at the close of the first fermentation, while the liquor is clear: embracing the critical time between the subsiding of the foulness caused by the motion, and the falling of the spume; a circumstance which frequently takes place a short time after the fermentation ceases; whereby the liquor is not only fouled, but is probably furnished with the seeds of a fresh fermentation.

"But rational as this theory may seem, there are men, whose characters class high as managers of fruit liquors, yet, who think it right to rack before the fermentation ceases; while the liquor is yet foul.

"In common practice, however, the liquor itself is seldom examined in judging of this nice point. Secondary criterions are applied to. Thus cyder, in the practice of some men, is racked when the brown crust becomes firm enough, and dry enough, not to stick to the finger on being touched; while others stay until the crust crack, and the white scum which has formed under it begin to rise through the cracks. The ordinary criterion of the time for racking perry is before it is done hissing. In the particular practice abovementioned, the guide is when it begins to twinge the nose: that is, when the gas flies off in quantity; which it does when the liquor is at the top of fermentation. While the makers of sweet liquors will not even hear them hiss, if they can possibly prevent the disagreeable sound.

"The method of racking is to draw off the clearer liquor, at a tap fixed above the lees, and to put it immediately into a fresh cask, duly seasoned. When it begins to run foul, the tap is stopt, and the remainder is filtered through flannel or canvas bags; filtering bags are made in the form of jelly bags, the mouth wide enough to receive a wooden hoop, a foot or fourteen inches in diameter: the depth eighteen inches or more, tapering to a point at the bottom. Where much racking is done, these bags are hung in a frame, about three feet high, holding perhaps a dozen bags, with tubs placed underneath to catch the filtered liquor; or for want of these, through a hair-cloth; the four corners being hung upon a hook; thus forming a kind of bag adequate to this purpose. The intention being merely that of separating the liquor from the lees and scum. The filtered liquor which ought to drop fine from the bag, is added to the rest; from which it differs in three notable

qualities: it is higher-coloured than that which has not mixed with the lees; it is no longer prone to fermentation; on the contrary, it is found to check that of the liquor racked off; and, another, if it afterward lose its brightness it is difficult to be recovered.

"The degree of fullness of the fresh cask seems to be pretty generally the same; the cask is not filled up; but left with about a pailful ullage; so that the surface of the liquor can just be touched with the finger; the bung being still left out.

"The number of rackings depend on the state of the liquor, and the judgment of the manager. If the fresh fermentation, which mostly commences, in some degree, after racking, become violent, it is generally understood, that the liquor ought to be racked again, to check it. Hence, in the practice of some men, the same liquor will be racked five or six times. On the contrary, if a small degree of fermentation, only, take place; which is in this case termed fretting; it is, in ordinary management, suffered to remain in the same cask: but the degree of fretting, which requires the operation of racking, is by no means settled: one man would rack the same cask of liquor, which another would leave for time to quiet. In the common practice of farmers, cyder is seldom or ever racked more than once; and perry is sometimes suffered to remain, until time render it quiet and fine, in the first cask, into which it was turned. The general idea seems to be, that frequent rackings weaken the liquor, and that much fermentation roughens it. The farmers, therefore, rather choose to be at the risque of losing the richness, than to lower the strength and bestow upon it the labour of racking.

"But those who manufacture the finer liquors for sale; especially, perhaps, those who have checked the first fermentation; think it prudent to repeat the rackings, until the liquor will lie quiet, or nearly so. If it cannot be brought into this state by ordinary racking, the fresh casks are fumigated with sulphur; whose fumes are found to have a power of silencing, or greatly checking, the fretting. This expedient is termed stumming the casks.

"The method of stumming them is this: matches, made of thick linnen cloth, about ten inches long, and an inch broad, thickly coated with brimstone about eight inches of their length, being prepared; and the cask properly seasoned; every vent is tightly stopt, except the bung-hole, a match kindled; lowered down into the cask, and held, by the end undipped, until it be well lighted, and the bung be driven in; thus suspending the lighted match within the cask. Having burnt so long as the contained air will supply the fire, the match dies; the bung is raised, the remnant of the match drawn out, and the cask suffered to remain, before the liquor be put into it, some two or three hours, more or less, according to the degree of force required. For a few days the liquor retains a sulphurous flavour, which, however, in a short time vanishes, and no evil effect, I understand, is found to follow the operation.

"Thus far the method of fermenting in casks: a mode of fermentation, which ninety-nine hogheads of a hundred, made in the country, are subjected to. Nevertheless there are some few men, in different parts of the district, who ferment either in vats or open vessels.

"One instance of this practice I met with in the Vale of Gloucester. In this instance the liquor is set in cows or other open tubs, or in casks with one of the heads out. In these vessels it stands until the first fermentation be pretty well over; when the spume is carefully skimmed off; under the idea that it is the scum mixing with the clear liquor, which causes it to fret after racking. The fermentation having ceased, and the lees subsided, the liquor is racked off into a fresh cask, and the lees filtered in the manner which has been described. In this practice, the liquor is never racked a second time.

"Another instance of fermenting in open vessels occurs in a practice which has been repeatedly mentioned, and which is entitled to the highest attention. It is generally spoken of as being, what I apprehend it really is, the first practice in the country. In this instance, the liquor is fermented in broad shallow vats; not less than five feet diameter, nor much more than two feet deep; each vat containing about two hogheads. In these vats the liquor remains until it has done rising; that is, until the fermentation has ceased, or nearly so; when it is racked off, without skimming; the critical juncture being caught before the spume begins to fall; the whole sinking gradually down together,

as the liquor is drawn off. In this practice, likewise, the liquor, notwithstanding its superior quality, is seldom racked a second time.

"Chemists enumerate three species of fermentation. The vinous, the acetous, and the putrefactive.

"The juices of some vegetable productions; as those of fruits which are inclined to sweetness; will, while recent and in their natural state, with a due degree of heat, and a free communication of air, pass spontaneously into the first or vinous fermentation: will acquire heat and motion, become turbid, and, at length, disentangle themselves from their impurities: throwing down part to the bottom of the containing vessel, part up to the surface; leaving, in the middle, a vinous liquor, furnished with a greater or smaller quantity of inflammable spirit. Thus wine, perry, cyder, and the different kinds of ale are vinous liquors; their various degrees of strength being given by the quantity of inflammable spirit they respectively contain.

"The vessel still kept open, so as to allow a free admission of air, the vinous liquor will pass on to the second stage of dissolution, the acetous fermentation: by which the inflammable spirit will be thrown off, and another precipitation of gross matter will take place; and the vinous liquor will now be changed into a dilute vegetable acid, or vinegar; of a strength proportioned to the quantity of spirit thrown off.

"The subject being still exposed, the third or last stage at length commences. The vinegar becomes putrid; its acid is destroyed; and the remaining contents of the vessel are found to be, simply, common earth and water.

"This being the nature of the expressed juices of fruit, the first object of the cyderist is to bring on a due degree of vinous fermentation; and his second, to prevent the vinous liquor from passing on to the acetous fermentation.

"But, notwithstanding this general theory of dissolution, science remains destitute of a satisfactory theory of the vinous fermentation. I have not, at least, after some search, been able to find any other than arrangements of well sounding words, pleasing enough to the ear, but affording the understanding no gratification. Even the first mover, the innate stimulus, the natural principle of this species of fermentation, does not evidently appear.

"In collecting and registering the foregoing particulars, respecting the fermentation of fruit liquor, many theoretic, as well as practical ideas were suggested by reflection. But though the former may contain a principal part of the theory required, they are, at present, in a state altogether unfit for publication.

"Therefore, all I shall attempt, in this place, is to explain more fully the general effect of the vinous fermentation, on the fruit liquors under notice, and endeavour to draw some practical inferences.

"The most striking effect is that of its giving strength to the liquor which, before its operation, was not possessed of that quality: effecting almost a total change of its original nature: not only by furnishing it with an intoxicating quality, which it was entirely free from; but in reversing, in a remarkable manner, its medical, and of course, its dietetic properties.

"Another notable effect is that of its destroying, or lessening, the sweetness of the liquor. The loss appearing, from the information, I am in possession of, to be in proportion to the strength acquired.

"This, as a general position, will, perhaps, be objected to. Good cyder is said to be made from ill-tasted fruit. The Hagloe crab is mentioned as an instance. But the harshness of this apple proceeds, I apprehend, from its flesh, and fibres, not from its juice; which, when fully matured, accords sufficiently with the idea here offered.

"Hence the difference between rough and sweet liquors: the fermentation of the former has continued until the whole or principal part of its sweetness was destroyed; that of the latter has ceased, or been checked, while a principal part of its sweetness remained.

"It does not follow, however, that roughness is a proof of strength, or sweetness of a want of body. Much depends on the nature of the fruit; and much, probably, on and state of ripeness. Rich well-ripened fruits afford sweetness enough to furnish a sufficiency of strength, and enough more to retain a sufficiency of richness in the liquor. On the contrary, liquor drawn from harsh and under-ripe fruit is exhausted of its sweetness, before it has acquired a redundancy of strength. Or, if the fermentation be checked to

preserve its sweetness, it is rendered of course deficient in strength.

"Hence the crude flatulent quality of the common sweet liquors, which are either weak through a want of fermentation, or, having been sufficiently fermented, have afterward been sweetened by art. A kind of liquor which is palatable enough to taste, but which, on being drank, soon becomes nauseous to the palate.

"And hence the preference to be given to liquors of a middle richness; strong without roughness, and rich without sweetness. A generous liquor, this, which, to use the good fellow's phrase, may be sat by. A liquor which is seldom met with out of this district, and not frequently in it. A liquor, nevertheless, which, I am fully persuaded, men in general would prefer to most foreign fruit liquors that are at present imported, in disgraceful abundance.

"In these observations, the methods of producing the different species of fruit liquor, namely, the rough, the sweet, and the generous, pretty evidently appear.

"To produce rough liquor, chuse austere fruits; grind them in a crude, unripe state, and subject the liquor to a full fermentation.

"To produce sweet liquor, make choice of the sweeter fruits; mature them fully, and check the fermentation of the liquor.

"The ordinary methods of checking the fermentation have been mentioned to be those of racking the liquor, and fumigating the fresh cask.

"But the use of racking is differently understood. The prevailing idea seems to be, that the fresh fermentation, or the fretting, is caused by the spume or dregs of the preceding; and that by racking the liquor off clear, into a clean vessel, the foulness is got rid of.

"But the manufacturers of sweet liquors rack under different motives. Their idea is, that racking cools the liquor, and by that means checks the fermentation. They observe, that the smaller the stream, in racking, the more the fermentation is restrained: and, in pursuance of the same idea, they frequently spread the liquor, thin, in open vessels, and sometimes agitate, or rather ventilate it, in this situation, and obtain the desired end by these expedients.

"It appears to me, however, that the end is gained, not altogether by giving coolness to the liquor (though in some degree it may) but by giving the principle of fermentation an opportunity of flying off. Filtering the liquor, drop by drop, is found not to check, but to destroy the fermentation. Filtered liquor is found even to lower the fermentation of others: not, certainly by its coolness; because in this it can differ very little from liquor which has been racked; the atmosphere, in both cases, presently reducing them to the same temperature; but probably, by the fermentative principle having escaped wholly from the one, its proportion is consequently lessened in the other.

"Hence (by the way) it is probable, that by filtering the fresh liquor from the press, a valuable antiscorbutic might be obtained; and, under the same idea, it appears probable that sweet liquors, duly manufactured, may have their medicinal virtues.

"But leaving this idea to those whom it more concerns, and such liquors to those who may require them, we will proceed to the production of one of a more generous nature: a liquor which those who drink for fashion or amusement, or to heighten their friendships, or lighten their cares, should encourage, and which the manufacturers of sale liquors will then, of course, endeavour to produce. At present, their whole skill is exhausted on the art of rendering their liquors unfit for ordinary drinking. They are not at present saleable, unless they are sweet.

"To produce liquors of a middle richness. Much depends on the nature of the fruit, and much on the season it is matured in. The fruits to be made choice of are such as yield juices capable of affording a sufficiency both of richness and strength. Such are the fire apple, the Hagloe crab, the Longney russet, the woodcock apple, the squash pear, and probably numberless other sorts, were their respective natures individually examined. Nevertheless, it is probable there are others which are altogether unfit for this purpose, consequently altogether unfit to encumber the ground they grow on.

"Much, however, depends on proper management. From what has gone before, it appears, that to produce a free fermentation, air and heat, atmosphere and warmth, are requisite. Warmth to set in action the fermentative principle; atmosphere to receive the loosened particles to be thrown off. But it also appears, that the ordinary heat of

of the atmosphere is, generally, more than sufficient to give the required degree of motion; and that, in the manufacturing of the fruit-liquors under notice, coolness, rather than warmth, is requisite.

"Hence the preference to be given to open vats, which at once preserve the required coolness, thereby preventing too furious a fermentation from taking place, and at the same time admit a sufficiency of surface, to render that which does take place, free and uninterrupted. Two hogheads of liquor, spread in the vats which have been described, expose some yards of naked surface; while the same quantity of liquor in casks, filled to the bungs, have only a few inches. The disproportion of surface more than a hundred to one.

"Hence it appears to me evident, that if liquors be fermented in casks, which only perhaps can be conveniently used on a large scale, they ought not to be filled, nor ought they, in my opinion, to lie on the bulge, in the usual manner, but to be set on end, with the heads out, and to be filled to such a height only as will produce the requisite degree of fermentation.

"In whatever situation the liquor is fermented, I am clearly of opinion the first effort of fermentation ought not, under ordinary circumstances at least, to be frustrated. But, on the contrary, the liquor ought to be allowed one full free fermentation; the degree being regulated, not by compulsory means, but by the depth of the liquor; and this by the heat of the air in the fermenting-room, and the quality of the liquor.

"But having passed through the first stage; having been racked in the proper juncture; and being found to have acquired a sufficient body, it may be right to prevent, as much as possible, a fresh fermentation. Rack, spread thin, or even filter, to keep it in the desired state.

"Correcting is, provincially, and aptly enough, termed *doctoring*; for the want of it implies disease. My enquiries, however, have been directed to the art of producing sound liquor, rather than to that of healing the unsound. Nevertheless, on digesting the general mass of information collected on the subject, I find a few ideas have, as it were, spontaneously offered themselves on this department of it.

"The imperfections which art undertakes to supply are, the want of strength, the want of richness, the want of flavour, the want of colour, and the want of brightness; consequently, with the addition of the other two qualities of fruit liquor, acidity, and aquosity, or, in plainer terms, vinegar and water, we have in our power the whole art of making cyder, without the trouble of planting orchards.

"The want of strength is supplied with brandy or other spirits, in sufficient quantity, to prevent liquor which has been made from under-ripe fruit, and has been imperfectly fermented, from being carried off by the acetous fermentation.

"The want of richness is supplied by what are generally termed *sweets*, prepared in a manner which I have not enquired after; nor has it fallen incidentally under my notice.

"To supply the want of flavour, an infusion of hops is sometimes added. This is said to communicate an agreeable bitter, and at the same time a fragrance; consequently becomes a substitute for the juices of the rind and kernels, thrown away to the pigs and poultry, through insufficient grinding; or given to the servants, through a want of proper pressing.

"The want of colour is sometimes supplied by elderberries ground among the fruit. These are said to give a fine colour, and a kind of flavour which is not disagreeable. But they are made use of, I understand, by individuals, chiefly or solely in making liquor for their own drinking. The universal colouring of the profession is burnt sugar, which gives the desired colour, and a degree of bitterness that is highly commended. There are two ways of preparing this colouring: one of them, by melting the sugar on a salamander, and suffering it to drop, as it melts, into water: the other, to boil the sugar (in this case brown sugar) over the fire, until it acquire an agreeable bitter; then pour in boiling water, in the proportion of a gallon to two pounds of sugar, and stir until the liquor become uniform. A pint of this preparation will colour a hoghead of cyder.

"Brightness is obtained through different means. In stubborn cases, when the foulness is great, and the liquor will neither fine nor fret, being what is technically termed *sulky*, yet is under circumstances which require that it should presently put on a cheerful countenance; it is

drenched with bullocks blood; namely, the blood of cattle or sheep: the blood of swine is rejected with judicial scrupulousness.

"The method of preparing and administering the blood is this: the only preparation of it is that of stirring it well, as it is drawn from the animal, to prevent its parts from separating. Stirring it one way is not deemed sufficient; it ought to be stirred both ways for about a quarter of an hour. The next thing is to enquire whether the liquor be in the mood for taking the blood, which it is not, it seems, equally at all times. This is done by repeating experiments with it in a phial: if it will take the blood in a phial, it will take it in the cask. A quart, or less quantity, is sufficient for a hoghead. After the blood is poured in, the liquor should be violently agitated, to mix the whole intimately together. This is done by a stick slit into four quarters, inserted at the bung-hole, and worked about briskly, every way among the liquor, until the whole be evenly blended. In about twenty-four hours the blood will be gone down, and the liquor ought to be racked; for by lying upon the blood, even two or three days, the liquor is liable to receive a taint, which is not easily got rid of. A most extraordinary effect of this process is, that the blood carries down not only the feculency, but the colour of the liquor, rendering it, though ever so highly coloured, limpid almost as water. This, however, is a loss which is the less regretted, as the means of restoring it are so easy and so effectual.

"The other forces made use of in giving brightness to cyder, are the common ones of eggs, and isinglass, (or a combination of the two) used as in the practice of wine-merchants, who, as well as the dealers in cyder, have of late years, it seems, made a free use of the blood.

"Laying up, is one of the most difficult steps to be taken in the management of fruit liquor, yet appears to be the least attended to or understood.

"The common practice is to bung up the casks in some particular month, or at some certain time, without any guide to discriminate the critical juncture when each individual requires to be shut up. Thus the early made liquor lies open until January or February; that made at Christmas is sometimes left open until March or April.

"The intention of securing the liquor from the outward air is, evidently, that of preventing the vinous liquor from pursuing its natural propensity, that of entering the acetous fermentation; which, according to the general law of nature, all vinous liquors become liable to, as has been already observed, on their being exposed to the outward air, and a moderate degree of heat. Hence, liquors which have passed the vinous fermentation, and are kept open until the warm air of spring begins to exert its influence, necessarily become vinegar, or enter into a stage of dissolution, which, if not timely interrupted, terminates in vinegar. Hence the number of casks of liquor, which are every year lost, or materially injured, through a want of due attention to the time of laying up.

"The only criterion I have met with for judging the critical time of laying up, is when a fine white cream-like matter first begins to form upon the surface. But this may be too late; it is probably a symptom, at least, of the acetous fermentation, which, if it takes place in any degree, must be injurious. Yet, if the casks be bunged tight, some criterion is necessary; otherwise, if the vinous fermentation have not yet finally ceased, or should recommence, the casks will be endangered, and the liquor injured. Hence, in the practice of the most cautious manager, whose practice I have had an opportunity of observing, the bungs are first driven lightly, when the liquor is fine, and the vinous fermentation is judged to be over; and some time afterward, when all danger is passed, to fill up the casks, and drive the bungs in securely, with a rag, and rosin them over the top. Some open the casks again at six weeks, to refill them; others think this unnecessary.

"It is an idea pretty generally received, I believe, among the farmers at least, that liquor, after it has done fermenting, that is to say, presently after the last racking, should have something to feed on. Hence some feed it with parched beans; others with egg-shells; others with mutton suet, to the quantity of half a pound, cut into pieces as big as the finger, to each hoghead; and a variety of other things are put in to make it keep. There are men, however, who consider this as a vulgar error; being of opinion, that liquor cannot be laid up too clean. Nevertheless, it appears to me more than probable, that, when there

is danger to be apprehended from the acetous fermentation, something may be useful. Ifinglass is thought, by a most intelligent manager, to be serviceable in this intention, which is in my idea that of fixing the principle of the acetous fermentation, or at least clogging it so far as to lessen its activity.

"The dealers lay up much of their liquor in large casks, containing from four or five to eight or ten hogheads (of 110 gallons) each. In these casks, good cyder will lie many years. In hogheads, it is sometimes kept three or four years. But it is observable, that if cyder be kept too long in cask, it loses much of its richness and flavour, growing what is provincially called stummy, loses its mellowness, and becomes heady. This perhaps is owing to a decay of the richness, which before sheathed part of the spirit; but being now lost, the spirit obtains full power of action.

"The usual place of laying up liquor is a cellar or a vault; or for want of this, a room so situated as not to be liable to sudden change of heat and cold.

"The proper age at which to bottle, depends on the quality of the particular liquor to be bottled. Good cyder is seldom fit for bottling before it be a year old. It is sometimes unfit for this operation until it be two years old; something depending on the size of the cask, as well as on the quality of the liquor: the larger the casks, the longer the liquor may be suffered to lie in them.

"In bottling, as in almost every other step to be taken in the art under notice, there is a critical time, which ought to be observed, and which in this case is not difficult to be ascertained. Whatever degree of richness and flavour the liquor has at the time of bottling, the same, or nearly the same qualities, it will preserve in bottles for many years. Hence the critical time of bottling is, when the liquor has acquired, in cask, its highest degree of perfection, whether that juncture happen in one or two years, or in a longer or shorter time.

"A person, who has paid especial attention to this subject, and whose liquor is become in a manner proverbial throughout the district, has observed, that liquor which has been bottled in the fulness of its richness and flavour, has been friendly to the habit, passing off chiefly by insensible perspiration; while the same liquor, suffered to remain in cask until it has passed this juncture, became armed at all points; distracting to the head, in the first instance, and injurious to the whole frame.

"It is needless to say that the liquor ought to be fine at the time of bottling. If not so at the critical time, the common force of eggs or ifinglass is made use of.

"It ought likewise to be bottled in cool weather, otherwise the bottles are more liable to fly.

"Good cyder should be kept as wine; and as this may be kept to almost any age, the several species of fruit liquor being very similar in their nature.

"Cyder, which has been sweetened with Lisbon sugar, by the London dealers, to suit the palates of their customers, is apt to fly: the bottles therefore in this case should be kept upright. Also when the liquor, though genuine, is bottled at an early age, the bottles, in the first instance at least, ought not to be laid down." See ORCHARD and PERRY.

CYTISUS, the name of a plant much cultivated by the old Romans for the food of cattle, and called by some, shrub trefoil, and by others shrub lucern.

It rises to the height of five, six, or even more feet, with a shrubby stalk, covered with a greyish bark, and divided into many branches, covered with a hoary down while they are young, and garnished at each joint with trifoliate leaves standing upon foot-stalks about an inch in length. There are two or three of these at each joint, so that the branches are closely covered with them. The lobes

are small, spear-shaped, and hoary on their under-side; and these leaves remain all the year. The flowers, which are of a bright yellow, blow on footstalks which arise from the sides of the branches, each footstalk sustaining four or five flowers, and these are succeeded by compressed moon-shaped pods, each containing three or four kidney-shaped seeds.

The cytissus may be raised either from its seed sown about the middle of October, or in the beginning of April; or if greater speed be desired, from cutting slips or layers, planted in the spring or autumn, so as to leave a space of four feet between each plant. Such are the directions of Columella; who adds, that if the ground be well dunged for this planting, and well hoed up round the plant, which should be watered during the first fortnight, if rain does not fall, plentiful crops may be obtained from this excellent vegetable, equally fit for horses, oxen, cows, sheep, hogs, goats, and poultry. It is also singularly profitable for bees, whose honey it increases prodigiously. It has the same effect upon the milk of cows, besides greatly improving its quality. In the kingdom of Naples the goats feed upon it, and great quantities of excellent cheese are made from their milk. In the islands of the Archipelago, the Turks make handles for their sabres of the wood of this shrub, which, when full grown, is as hard as ebony, and of a fine yellow colour. It will bear cutting as often as its shoots are about fifteen or eighteen inches long, which may be several times in the year; for it shoots and flowers during eight months in the countries where it grows well, and continues green during the whole winter, if the season be at all favourable. Its seeds begin to ripen towards the end of August, and continue to do so until the cold stops them. It will be fit for cutting at the end of three years at farthest, and should be carefully kept clear of weeds, and hoed up between each cutting. If given as green fodder, which it affords during eight months of the year, about fifteen pounds weight of it are sufficient for the daily food of a horse, twenty pounds for an ox, and so in proportion for other cattle, according to their size and strength. When made into hay, it should be given more sparingly, because it is then more nourishing. In this state it should be steeped in water, before it is given to cattle, and then be mixed with chaff or straw. The time of cutting it for hay, is when the greater part of its seeds begin to grow large; and the manner of making this hay is, to let the swarths lie some hours in the sun, till they are faded, and then to dry them thoroughly in the shade. *Columella de Rustica, lib. V. cap. 12.*

Mr. Miller allows the cytissus every quality that can recommend it for the feeding of cattle in the countries where it grows naturally, such as the islands of the Archipelago, Sicily, and the warmest parts of Italy; but is persuaded that it will not thrive in England, so as to be of any real advantage for that purpose here, because it cannot bear such hard frosts as we sometimes have; or if it does not bear them so far as not to be absolutely killed, it will be so much damaged thereby, as not to be able to recover its verdure before the middle or latter end of May, nor even then, to put forth shoots that will bear cutting more than once in a summer; besides, their being so woody, if suffered to grow to any considerable length, as to render that cutting very troublesome, and of little service by way of fodder. He therefore thinks, upon the whole, that it can never answer the trouble and expence of cultivation in this country, where we have many other preferable plants; but that in hot, dry, rocky countries, of which we have now several in our colonies, where few other vegetables will thrive, this may be cultivated to great advantage, for it will live there many years, and prosper very well.

D.

DAB-CHICK, a chick newly hatched.

DAG, dew hanging upon the grass.

DAIRY, the occupation or art of making various kinds of food from milk, particularly butter and cheese. It also signifies the place where these operations are performed.

The following account of managing a dairy was written by a gentleman who has, for a considerable number of years, employed himself in that business, and acquired by his industry a plentiful fortune.

He begins with recommending the cultivation of sainfoin to every person concerned in a dairy, as it is observed to increase the milk of cows, both in quantity and quality, above any artificial pasture yet known, and therefore he advises the farmer to keep his cows upon it, and form a five years dairy.

"An acre of the worst land, continues he, will, when improved by this grass, maintain four cows very well from the first of April to the end of November, and afford besides a sufficient store of hay, to make the greater part of of their subsistence the four winter months following. You must buy then about four hundred milch-cows, but take care you chuse them with judgment. I have bought your largest sort of runts from Wales for less than fifty shillings a cow, with a good calf by her side, which I always disposed of as soon as I could. You will observe, that I make too good an use of the milk to afford the calf his share of it. I generally keep these cows above twelve months, and then selling them, sometimes for four pounds a piece, I stock myself with such that are new-milched. I observe this rule every year, and the trouble is sufficiently rewarded by the advantage it brings me; for besides the profit I make by selling dearer than I buy, I avoid the inconvenience of having any thing to do with bulls, and the consequences; so that I always preserve my cows in their full milk, and find it no uncommon thing for one of these milch-cows to be milked twice a day, and afford a gallon and a half at a meal. Four hundred of these cows will cost a thousand pounds; and you will find, that coming from a poor pasture to a rich, they will prosper and increase both in milk and size. In eight convenient places about your hundred acres let there be built eight thatched sheds; a little rising in the middle to carry off the water; the height may be ten feet, and the breadth thirty; each of these sheds should be a hundred and twenty-five feet long, and, under the highest part, directly in the middle, you must raise a slight partition, lathed and plastered, which serves to support the ridge of the roof, while the two sides are sustained by square wooden posts, about eight feet high, and placed at proper distances.

"On either side of the partition wall let there be fixed a kind of a rack, like those in stables, which is to run the whole length of the shed, and must be placed as high as a cow can reach her fodder from. The shed must next be divided into stalls, like those for stone-horses, and each stall will be above five feet broad; the length of these stalls must be exactly fitted to that of a cow, that a cross bar, being placed at the outward end, may keep the beast from running backwards: thus every shed will hold fifty cows, five and twenty on each side of the partition: to every one of these sheds you must appoint a man, whose business it will be to clear the place, and carry off the dung; as also to mow the sainfoin every day, and give it to the cows in the rack before-mentioned: this man beginning at one end of his proportion of ground, and going gradually on to the other, the first place will always be fit to mow again by that time he has gone through his whole division. Your cows are thus fed at discretion, with neither too much nor too little; they are not pestered with the scorching heats, nor troubled with the stinging-fly, which, in open pastures, often makes them walk about, and trample down more grass than they eat. At each end of every shed you must build a slight

room of brick, thirty feet square, and ten feet high, which is to be divided, the cross-way of the shed, into two partitions, each fifteen feet broad, and thirty feet long; that which joins the cow-house must be paved with tiles, and is to serve for a dairy; the other must be floored and windowed, and is to be a lodging-room for the dairy-maids. Every shed will require five maids, that is, to every ten cows one dairy-maid; fewer might serve, but it is better to exceed, than fall short in this particular. Thus each dairy will have two or three maids belonging to it, whose lodging will be the room adjoining, and whose care is to extend to the shed on both sides the partition, to the five and twenty cows which are the nearest to their station. All along both sides of the partition, at about a foot above the ground, let there be fixed, close to the wall, a strong pipe of lead, a little less than an inch diameter; both which pipes, being somewhat raised exactly in the middle of the shed, must have a gentle and almost an invisible descent from that rising to the dairies, through the wall of which their nether ends are to be brought, and there wrought into one another, that whatever descends through them, into either of the dairies, may have issue but at one mouth. This mouth of the pipes must be made very small, and neatly fitted into the hollow end of a strong wooden axle-tree; which, whilst it is turning swiftly round the mouth of the pipe, may by no means strain it by the motion, but receive, into its own hollow, the milk which descends through the leaden pipes, without spilling any, and passes so far through a wheel, or vessel like a barrel, only much larger in its circumference. The axle-tree, which this vessel is to turn upon, is bored very full of round holes, through which it delivers the milk into the vessel, as fast as it receives from the pipe.

"The vessel must be capable of containing, at least, three times the quantity of milk which is designed to receive; and there must be six wings, or thin pieces of wood, glued on edge-ways to the wooden axle-tree, whose length and breadth must be so contrived, as to leave a free space of six inches at either end of the axle-tree, and a foot between their edges length-ways, and the smooth inside of the vessel; in the most convenient part of which must be contrived a door, to open and shut down upon occasion, as closely as if there was none. This door will perform its work very neatly, if you line the inside and edges with some kind of cloth, which is commonly used in the pressing of cheese. The other solid end of the axle-tree must extend itself about five feet longer; and the whole length may be supported by square wooden posts, and turn in their tops, which are to be made hollow, and kept greased for that purpose. This end of the axle-tree is to be fastened into a wheel, exactly like those which are used in many places for roasting of meat. The diameter of this last wheel must be within six inches of the height of the dairy, and two or three large dogs being put into it at a time, will turn it with extraordinary swiftness: the dogs are easily taught, and will at last take delight in the exercise. I have brought up a large buck to the practice of this labour, and it is wonderful to see the force with which he runs round an hour or two together, and turns a wheel of ten feet diameter; but you must make your wheel as light as it can possibly hold together. I have but one thing more to say, and I finish this direction; pretty near that side of every stall in your shed, to which the maid must come to milk the cow which belongs to it, let a hole, as small as will serve the occasion, be contrived by your plumber, in the uppermost part of the leaden pipe, to shut and open with a little screw, which screw, for fear of losing it, may be fastened by a little iron chain to the body of the pipe. I have endeavoured, in the description of all this, to make my meaning as plain as possible, and hope the reader will, with a little attention, comprehend the whole."

The ingenious Mr. Lisle observes, that so much cleaning and scalding is necessary, that the dairy farmers spend as much

wood

is danger to be apprehended from the acetous fermentation, something may be useful. Ifinglass is thought, by a most intelligent manager, to be serviceable in this intention, which is in my idea that of fixing the principle of the acetous fermentation, or at least clogging it so far as to lessen its activity.

"The dealers lay up much of their liquor in large casks, containing from four or five to eight or ten hogheads (of 110 gallons) each. In these casks, good cyder will lie many years. In hogheads, it is sometimes kept three or four years. But it is observable, that if cyder be kept too long in cask, it loses much of its richness and flavour, growing what is provincially called stummy, loses its mellowness, and becomes heady. This perhaps is owing to a decay of the richness, which before sheathed part of the spirit; but being now lost, the spirit obtains full power of action.

"The usual place of laying up liquor is a cellar or a vault; or for want of this, a room so situated as not to be liable to sudden change of heat and cold.

"The proper age at which to bottle, depends on the quality of the particular liquor to be bottled. Good cyder is seldom fit for bottling before it be a year old. It is sometimes unfit for this operation until it be two years old; something depending on the size of the cask, as well as on the quality of the liquor: the larger the casks, the longer the liquor may be suffered to lie in them.

"In bottling, as in almost every other step to be taken in the art under notice, there is a critical time, which ought to be observed, and which in this case is not difficult to be ascertained. Whatever degree of richness and flavour the liquor has at the time of bottling, the same, or nearly the same qualities, it will preserve in bottles for many years. Hence the critical time of bottling is, when the liquor has acquired, in cask, its highest degree of perfection, whether that juncture happen in one or two years, or in a longer or shorter time.

"A person, who has paid especial attention to this subject, and whose liquor is become in a manner proverbial throughout the district, has observed, that liquor which has been bottled in the fulness of its richness and flavour, has been friendly to the habit, passing off chiefly by insensible perspiration; while the same liquor, suffered to remain in cask until it has passed this juncture, became armed at all points; distracting to the head, in the first instance, and injurious to the whole frame.

"It is needless to say that the liquor ought to be fine at the time of bottling. If not so at the critical time, the common force of eggs or ifinglass is made use of.

"It ought likewise to be bottled in cool weather, otherwise the bottles are more liable to fly.

"Good cyder should be kept as wine; and as this may be kept to almost any age, the several species of fruit liquor being very similar in their nature.

"Cyder, which has been sweetened with Lisbon sugar, by the London dealers, to suit the palates of their customers, is apt to fly: the bottles therefore in this case should be kept upright. Also when the liquor, though genuine, is bottled at an early age, the bottles, in the first instance at least, ought not to be laid down." See ORCHARD and PERRY.

CYTISUS, the name of a plant much cultivated by the old Romans for the food of cattle, and called by some, shrub trefoil, and by others shrub lucern.

It rises to the height of five, six, or even more feet, with a shrubby stalk, covered with a greyish bark, and divided into many branches, covered with a hoary down while they are young, and garnished at each joint with trifoliate leaves standing upon foot-stalks about an inch in length. There are two or three of these at each joint, so that the branches are closely covered with them. The lobes

are small, spear-shaped, and hoary on their under-side; and these leaves remain all the year. The flowers, which are of a bright yellow, blow on footstalks which arise from the sides of the branches, each footstalk sustaining four or five flowers, and these are succeeded by compressed moon-shaped pods, each containing three or four kidney-shaped seeds.

The cytissus may be raised either from its seed sown about the middle of October, or in the beginning of April; or if greater speed be desired, from cutting slips or layers, planted in the spring or autumn, so as to leave a space of four feet between each plant. Such are the directions of Columella; who adds, that if the ground be well dunged for this planting, and well hoed up round the plant, which should be watered during the first fortnight, if rain does not fall, plentiful crops may be obtained from this excellent vegetable, equally fit for horses, oxen, cows, sheep, hogs, goats, and poultry. It is also singularly profitable for bees, whose honey it increases prodigiously. It has the same effect upon the milk of cows, besides greatly improving its quality. In the kingdom of Naples the goats feed upon it, and great quantities of excellent cheese are made from their milk. In the islands of the Archipelago, the Turks make handles for their sabres of the wood of this shrub, which, when full grown, is as hard as ebony, and of a fine yellow colour. It will bear cutting as often as its shoots are about fifteen or eighteen inches long, which may be several times in the year; for it shoots and flowers during eight months in the countries where it grows well, and continues green during the whole winter, if the season be at all favourable. Its seeds begin to ripen towards the end of August, and continue to do so until the cold stops them. It will be fit for cutting at the end of three years at farthest, and should be carefully kept clear of weeds, and hoed up between each cutting. If given as green fodder, which it affords during eight months of the year, about fifteen pounds weight of it are sufficient for the daily food of a horse, twenty pounds for an ox, and so in proportion for other cattle, according to their size and strength. When made into hay, it should be given more sparingly, because it is then more nourishing. In this state it should be steeped in water, before it is given to cattle, and then be mixed with chaff or straw. The time of cutting it for hay, is when the greater part of its seeds begin to grow large; and the manner of making this hay is, to let the swarths lie some hours in the sun, till they are faded, and then to dry them thoroughly in the shade. *Columella de Rustica, lib. V. cap. 12.*

Mr. Miller allows the cytissus every quality that can recommend it for the feeding of cattle in the countries where it grows naturally, such as the islands of the Archipelago, Sicily, and the warmest parts of Italy; but is persuaded that it will not thrive in England, so as to be of any real advantage for that purpose here, because it cannot bear such hard frosts as we sometimes have; or if it does not bear them so far as not to be absolutely killed, it will be so much damaged thereby, as not to be able to recover its verdure before the middle or latter end of May, nor even then, to put forth shoots that will bear cutting more than once in a summer; besides, their being so woody, if suffered to grow to any considerable length, as to render that cutting very troublesome, and of little service by way of fodder. He therefore thinks, upon the whole, that it can never answer the trouble and expence of cultivation in this country, where we have many other preferable plants; but that in hot, dry, rocky countries, of which we have now several in our colonies, where few other vegetables will thrive, this may be cultivated to great advantage, for it will live there many years, and prosper very well.

D.

DAB-CHICK, a chick newly hatched.

DAG, dew hanging upon the grafs.

DAIRY, the occupation or art of making various kinds of food from milk, particularly butter and cheefe. It also fignifies the place where thefe operations are performed.

The following account of managing a dairy was written by a gentleman who has, for a confiderable number of years, employed himfelf in that bufinefs, and acquired by his induftry a plentiful fortune.

He begins with recommending the cultivation of fainfoin to every perfon concerned in a dairy, as it is obferved to increafe the milk of cows, both in quantity and quality, above any artificial pafture yet known, and therefore he advifes the farmer to keep his cows upon it, and form a five years dairy.

"An acre of the worft land, continues he, will, when improved by this grafs, maintain four cows very well from the firft of April to the end of November, and afford befides a fufficient ftore of hay, to make the greater part of of their fubfiftence the four winter months following. You muft buy then about four hundred milch-cows, but take care you chufe them with judgment. I have bought your largeft fort of runts from Wales for lefs than fifty fhillings a cow, with a good calf by her fide, which I always difpofed of as foon as I could. You will obferve, that I make too good an ufe of the milk to afford the calf his fhare of it. I generally keep thefe cows above twelve months, and then felling them, fometimes for four pounds a piece, I ftack myfelf with fuch that are new-milched. I obferve this rule every year, and the trouble is fufficiently rewarded by the advantage it brings me; for befides the profit I make by felling dearer than I buy, I avoid the inconvenience of having any thing to do with bulls, and the confequences; fo that I always preferve my cows in their full milk, and find it no uncommon thing for one of thefe milch-cows to be milked twice a day, and afford a gallon and a half at a meal. Four hundred of thefe cows will coft a thoufand pounds; and you will find, that coming from a poor pafture to a rich, they will prosper and increafe both in milk and fize. In eight convenient places about your hundred acres let there be built eight thatched fheds; a little rifing in the middle to carry off the water; the height may be ten feet, and the breadth thirty; each of thefe fheds fhould be a hundred and twenty-five feet long, and, under the higheft part, direftly in the middle, you muft raife a flight partition, lathed and plaftered, which ferves to fupport the ridge of the roof, while the two fides are fupported by fquare wooden pofts, about eight feet high, and placed at proper diftances.

"On either fide of the partition wall let there be fixed a kind of a rack, like thofe in ftables, which is to run the whole length of the fhed, and muft be placed as high as a cow can reach her fodder from. The fhed muft next be divided into ftalls, like thofe for ftone-horfes, and each ftall will be above five feet broad; the length of thefe ftalls muft be exactly fitted to that of a cow, that a crofs bar, being placed at the outward end, may keep the beaft from running backwards: thus every fhed will hold fifty cows, five and twenty on each fide of the partition: to every one of thefe fheds you muft appoint a man, whofe bufinefs it will be to clear the place, and carry off the dung; as alfo to mow the fainfoin every day, and give it to the cows in the rack before-mentioned: this man beginning at one end of his proportion of ground, and going gradually on to the other, the firft place will always be fit to mow again by that time he has gone through his whole divifion. Your cows are thus fed at difcretion, with neither too much nor too little; they are not pefttered with the fcorching heats, nor troubled with the flinging-fly, which, in open paftures, often makes them wifk about, and trample down more grafs than they eat. At each end of every fhed you muft build a flight

room of brick, thirty feet fquare, and ten feet high, which is to be divided, the crofs-way of the fhed, into two partitions, each fifteen feet broad, and thirty feet long; that which joins the cow-houfe muft be paved with tiles, and is to ferve for a dairy; the other muft be floored and windowed, and is to be a lodging-room for the dairy-maids. Every fhed will require five maids, that is, to every ten cows one dairy-maid; fewer might ferve, but it is better to exceed, than fall fhort in this particular. Thus each dairy will have two or three maids belonging to it, whofe lodging will be the room adjoining, and whofe care is to extend to the fhed on both fides the partition, to the five and twenty cows which are the neareft to their ftation. All along both fides of the partition, at about a foot above the ground, let there be fixed, clofe to the wall, a ftrong pipe of lead, a little lefs than an inch diameter; both which pipes, being fomewhat raifed exactly in the middle of the fhed, muft have a gentle and almoft an invifible defcent from that rifing to the dairies, through the wall of which their nether ends are to be brought, and there wrought into one another, that whatever defcends through them, into either of the dairies, may have iffue but at one mouth. This mouth of the pipes muft be made very fmall, and neatly fitted into the hollow end of a ftrong wooden axle-tree; which, whilft it is turning fwiftly round the mouth of the pipe, may by no means ftrain it by the motion, but receive, into its own hollow, the milk which defcends through the leaden pipes, without fpillling any, and paffes fo far through a wheel, or vefel like a barrel, only much larger in its circumference. The axle tree, which this vefel is to turn upon, is bored very full of round holes, through which it delivers the milk into the vefel, as faft as it receives from the pipe.

"The vefel muft be capable of containing, at leaft, three times the quantity of milk which is defigned to receive; and there muft be fix wings, or thin pieces of wood, glued on edge-ways to the wooden axle-tree, whofe length and breadth muft be fo contrived, as to leave a free fpace of fix inches at either end of the axle-tree, and a foot between their edges length-ways, and the fmooth infide of the vefel; in the moft convenient part of which muft be contrived a door, to open and fhut down upon occafion, as clofely as if there was none. This door will perform its work very neatly, if you line the infide and edges with fome kind of cloth, which is commonly ufed in the preffing of cheefe. The other folid end of the axle-tree muft extend itfelf about five feet longer; and the whole length may be fupported by fquare wooden pofts, and turn in their tops, which are to be made hollow, and kept greafed for that purpofe. This end of the axle-tree is to be faftened into a wheel, exactly like thofe which are ufed in many places for roafting of meat. The diameter of this laft wheel muft be within fix inches of the height of the dairy, and two or three large dogs being put into it at a time, will turn it with extraordinary fwiftness: the dogs are eafily taught, and will at laft take delight in the exercife. I have brought up a large buck to the practice of this labour, and it is wonderful to fee the force with which he runs round an hour or two together, and turns a wheel of ten feet diameter; but you muft make your wheel as light as it can poffibly hold together. I have but one thing more to fay, and I finifh this direftion; pretty near that fide of every ftall in your fhed, to which the maid muft come to milk the cow which belongs to it, let a hole, as fmall as will ferve the occafion, be contrived by your plumber, in the uppermoft part of the leaden pipe, to fhut and open with a little fcrew, which fcrew, for fear of loofing it, may be faftened by a little iron chain to the body of the pipe. I have endeavoured, in the defcription of all this, to make my meaning as plain as poffible, and hope the reader will, with a little attention, comprehend the whole."

The ingenious Mr. Lifle obferves, that fo much cleaning and fcaiding is neceffary, that the dairy farmers fpend as much wood

wood in fire for that purpose, during the summer, as they burn for other purposes in the winter.

If the milk vessels are not kept clean they will be sour, and the cheese will be sour before it can come, and it will eat sour and choaky. A cold dairy is a great means of preserving cream from turning sour. The milk-houses should also be large, for otherwise the steam arising from the hot milk as brought in from the cows will heat the air of the room.

Care should be taken when cows begin to give off their milk, to milk them clean; for if this be neglected they will soon grow dry. Cows generally begin to give off the height of their milk about the time of the blossoming of the wheat, and continue so till a good aftermath comes on, when their milk will increase; but cold and rainy weather in the autumn will soon abate their milk again. Perhaps the reason why the milk of cows abates about wheat blossoming time is, because about that time the grass of the field blossoms also, and the flush of the sap is come to its height and maturity, and then abates, for the roots of the grass at that time begin to harden and grow dry; nor do they take in the juices of the earth so freely as they did before, and therefore grow drier and drier, till the seed is hardened. The seed being thus brought to maturity, the roots of the grass for some time, till the cold of the winter checks them, strike fresh sap roots, or buds, preparative to the ensuing spring, and which will the next year be the spring roots and increase. On these new efforts the start of the autumn grass depends, till the cold checks it. The grass is called the aftermath, and upon the growth of this the cows milk depends.

It has been observed, that the milk of the hill-country cows do not yield the same proportion of cream as that of the Vale cows; owing, in all probability, to the poverty of the hill-country cows, which are generally poor in case.

Thunder will break the cream, and turn the milk in the milk-pans, so that no cream can be skimmed off for butter; nor will the cheese-curd hold together, but will break asunder.

It is commonly said, that a quart of cream will make a pound of butter; but this must be understood of cream that hath stood two or three days to settle, for three pints of cream just skimmed from the milk, will, in three days, be reduced to nearly a quart. If you bring in the milk and strain it immediately into the pans, without letting it first stand to cool, the cream produced by it will be much less than it would have been if the milk had been suffered to stand and cool before straining.

In some parts of Devon and Dorsetshire, they set the milk over the fire in brass pans to warm, which makes the cream rise, and when a bladder is formed in the middle, they take the pans from the fire, skim off the cream, and put it into a tub. After this the dairy-maid, by only putting her hand, and stirring it about in the tub, brings it presently to butter, without the help of a churn. The butter made by this method is very rich, but the cheese made from the skim-milk very poor. See the article BUTTER, CHEESE.

The hill-country farms are not so well adapted to a dairy as those in the Vale; because the foddering season in the former holds so much longer, occasioned by the rowet-grass falling off a month sooner, and the spring-grass coming a month later than in the Vale. *Lisle's Husbandry*, vol. II. p. 139.

Mr. Marshall, in his *Rural Economy of the Midland Counties*, is copious on the subject of the dairy and says,

"The size of dairies has of course increased with that of farms. A hundred cows are, nevertheless, considered as a very large dairy: there are few so large. Forty or fifty cows are considered as a dairy above the middle size.

"The species of cow, here, as in the Upper Vale, is indeterminate. Gloucestershire, north-country, and a mongrel breed, between the two. Five years ago it was said that the north country cows were losing ground: and that the old stock were coming again into esteem.

"I remember the observation of an experienced dairy-woman in 1783 was, that the north-country cows neither milk so well nor fat so well as the true dark-brown Gloucestershire breed. Nevertheless, I cannot perceive that they have made any progress. On the contrary the long-horned breed appear to have increased since that time.

"A man whose knowledge of the rural affairs of this district, and of the several breeds of cattle of this quarter of the island, is extensive, and whose remarks are seldom superficial, sees this recent increase of the northern breed of

cows in a point of view which seems to have escaped the observation of others. He is of opinion, that it has been effected by other circumstances than the comparative merits of the two breeds of cows; which, he thinks, has had little or no influence in the change that has been taking place. He attributes it to the advanced price of dairy produce, during a succession of years last past. The dairy being found, in this well soiled dairy country, to pay better than breeding; this of course declined: and, as the young stock diminished, the quantity of vacant pasture increased: consequently an increase of alien cows became doubly requisite. This increase was not to be obtained from the Gloucestershire breed; nor could the supply be drawn from the kindred breeds of the neighbouring districts; nor perhaps from any other source than that from which it has been principally drawn: namely the north of Staffordshire; where breeding is the principal object, and where the produce of the dairy is of much less value than it is in the Vales of Gloucestershire.

"Certain it is, that on farms, whose grounds, by soil and situation, are wholly adapted to the dairy, we see the greatest proportion of north country cows; while on those which have rough or distant grounds belonging to them, adapted to breeding, the Gloucestershire cows still hold possession; and, by those who have them, are still in the highest esteem.

"Impressed with these ideas, the ingenious author of these remarks is of opinion, that should the dairy continue, for a length of years in its present declining state; especially if breeding should continue to pay so well as it has lately done; the influx of alien cows will be stopped; their prices will no longer be a temptation to the dealers, and their places in the pastures will be occupied by rearing stock: not of the north-country, but of the Gloucestershire breed.

"Be this as it may, it is, I believe, a well-known fact, that the cheese of this district has been falling off, in point of superior excellency, since about the time of the introduction of north-country cows; and an advocate for the Gloucestershire breed would of course argue, that the north-country cows are unfriendly to cheese. On the contrary, however, it is asserted, by those who are the best authority in this case (the cheese factors) that there are dairies consisting wholly of north-country cows, which make cheese of the first quality. While the advocates for the breed assert, that their milk not only makes cheese of a good quality, but that it affords a greater proportion of curd, than that of the Gloucestershire breed.

"Upon the whole, therefore, we have sufficient evidence I think, to conclude, that the superior excellency of the Berkeley cheese is not, nor ever was, owing to the species of cow.

"The cow management, here, is similar to that of the Upper Vale: except that a smaller proportion are bred in this Vale: the richer lands having been considered, of late years at least, as too good for breeding. On the skirts of the hills, and on the colder lands, there are, nevertheless, many breeding farms. The north country sort are bought of the jobbers at Gloucester. As they fail in their milk, they are put to fattening on the dairy farm, or sold to graziers.

"A defect which has, it seems, lately crept into the management of cows in this Vale is noticeable. The cows, of many dairies, are said to come in too early in the spring: their milk is spent before the autumnal flush of grass sets in. The cool months of autumn are not only favourable to the manufacture of cheese; but the milk, of that season, is thought to yield a greater proportion of curd, than that of the summer months. I mention this as the observation of a man who is singularly entitled to attention; being intimately acquainted with every department of the dairy management of this country. But may not this deficiency of autumnal produce be in some measure owing to the nature of the long-horned cows? which, though they afford a flush of milk presently after calving, are observed, (the higher bred ones at least) to lose it much sooner than those of most other breeds.

"In the choice of cows, dairy farmers are guided by different criterions.

"The Derbyshire cow remains the favourite of the old dairies. They argue, that the grazier and the dairy-man, distinctly considered, require different animals to suit their respective purposes. The dairier's object is milk; the grazier's beef; and it is a trite remark, among dairy-men in different districts, that a cow which runs to beef is unprofitable to the dairy: for notwithstanding the excellency of her

her bag, and the plentifulness of her milk, presently after calving, her natural inclination to fleshiness draws off her milk : while a cow that is by breed, or natural constitution, prone to milk, will supply this, at the expence of her carcase, let her pasture be ever so plentiful.

" These popular opinions, however, though they contain much truth, are not altogether well founded. They hinge on a false principle. Cows are useful, and in a great degree necessary, in a twofold capacity : as dairy-cows, and as grazing stock : the dairy-man and the grazier cannot have distinct animals : one and the same individual must serve both their purposes. And a breed of cows, fit for the grazier only, is, in a general light, not less eligible, than a breed which is fit only for the dairy-man.

" The Derbyshire cows are unprofitable as grazing stock. They have neither beauty nor utility of form ; being loaded with offal of every kind. The head thick, the chap and neck foul, the bone proportionably large, the hide heavy, and the hair long ; even the bag is not unfrequently so overgrown, as to be almost hid in hair ; a point of milking cows to which dairy-women, of most districts, have an objection : this, however, only serves to shew that popular criterions are seldom to be depended upon. Were the flesh and fatting quality of the Derbyshire cows equal to their quality as dairy cows, the hairiness of their bags might well be dispensed with.

" The Staffordshire cows bear a different characteristic. Taking them together, they are rather adapted to grazing, than the dairy ; most of them being tolerably clean. But, in general, they are too gaunt in their carcases to be eligible, either as dairy or grazing stock.

" Nevertheless, there are individuals of this breed ; or rather, perhaps, of a breed between this and the Derbyshire ; that may be said to be at once eligible as dairy cows and grazing stock. At least, they come nearer my idea of what a cow ought to be, than any other breed or variety of the long-horned breed, I have yet had an opportunity of observing.

" Whether the individuals, now under notice, have or have not been produced by a mixture of the Staffordshire and Derbyshire blood, they are the most prevalent on the banks of the Trent, which divides the two counties ; it is, indeed, the breed which is there found, more particularly on the Derbyshire side, from Walton towards Stanton, which falls under this description.

" The following are accurate dimensions of a middle-aged cow of this kind ; somewhat low in flesh, and young in calf.

" Height at the withers, four feet two inches and a quarter.

" ——— of the brisket, nineteen inches.

" Smallest girt, six feet five inches.

" Largest girt, seven feet eight inches and a half.

" Length from forehead to nache, seven feet three inches.

" ——— from shoulder-knob to the center of the hip, three feet eight inches.

" ——— from the center of the hip to the out of the nache, twenty-one inches.

" Width at the shoulders, twenty inches.

" ——— at the hips, twenty-two inches.

" ——— the nache, thirteen inches.

Length of the horns, twenty-four inches ; their width from point to point, three feet four inches.

" The forend fine, long, and standing low.

" The head small, and the neck thin, but deep, according with the depth of her bosom.

" The shoulders fine, the ribs full, and the loin broad.

" The thighs remarkably thin below, as if to give room to her bag, large, clean, and bladder-like ; with long teats, and remarkably large elastic milk veins ; furnishing an ample supply of milk.

" The legs short, with the bone fine (7½ inches girt).

" The flesh good, and the hide of a middle thickness.

" The colour a brindled mottle, with a finch back, and white legs.

" In temper remarkably cadish, gentle ; a quality of considerable value, in a cow intended for the pail.

" The principal distinction observable between the form of what is here spoken of as a dairy cow, and that of a cow of the modern breed, or what is more generally understood by a good grazier's cow, is, the former is more roomy and better let down in the chest ; the latter, better topped ; fuller on the chine and loin ; and, generally, fuller in the thigh. Both of them are clean in the forend and shoulder ;

the bone in both is fine ; the flesh of both good (but that of the modern breed indisputably better) ; and their hides of a middle thickness.

" But the most material difference, and that which determines the dairy-man in his choice, is, the one loses her milk a few months after calving ; the other, if required, will milk the year round.

" In the summer management of dairy cows, I have met with nothing of superior excellence in this district. They are turned to grass, about May-day ; allowing from an acre and half to two acres to a cow : kept generally in one and the same pasture, until aftergrass be ready to receive them ; and have turneps thrown to them (by those who grow turneps) on grassland, in autumn.

" In this district, however, one instance of practice occurred to me which requires to be registered ; namely, that of a dairy of fourteen or fifteen cows being principally dried off together, on one day (the middle of December) ; preserving two or three, only, in milk, for the family, during the winter months ; keeping these at hay ; putting the dried cows to straw ; for which purpose, only, they were dried off in this remarkable manner.

" It is observable, however, that this practice can be eligible only, when cows come well in together : to effect which they are bulled as fast, that is to say as near together, as possible.

" Unnatural as this expedient will no doubt be deemed by many, it may, nevertheless, in some cases, be eligible : all I shall say farther of it is, that if I had not observed it in the practice of one of the oldest and best managers in the district, I should not have registered it.

" In the winter management of dairy cows, one circumstance may be noticed ; that of their being frequently kept (in conformity to a modern practice adopted by some leading men) in sheds, which have been described under the head buildings, continually throughout winter, from the time of their being taken up in autumn, to that of their being turned to grass in the spring, generally four months, without any exercise.

" Some discerning individuals, however, have already discovered the inconveniences of this practice, especially that of their hoofs cracking ; let them loose in a yard, a few hours every day, to moisten their feet, as well as to exercise their legs, and clean their coats.

" In what might be called the natural practice of the district, dairy farmers not only rear but fat their own cows. One of the largest farmers in the district told me that he never bought a cow in his life, he rears fifteen, eighteen, or twenty calves yearly, and fats his own stock ; or, for want of room, sells them to graziers.

" This forms a beautifully simple plan of management ; well adapted to a middle soil farm ; and especially eligible for gentlemen, and others, who are deficient in judgment, and unacquainted with markets. The proportion of grass and arable being determined upon, and the quantity of stock ascertained, the machine is regulated, and nothing but a due attention to the number of heifers, annually reared, is wanted to keep it in continual and uniform motion. A certain number of dairy cows, with a lot of fatting cattle, and another of young stock to follow them, in summer, and to eat straw in winter. No going to market, but with corn, dairy produce, and cullen cows. A plan of general management, beautiful in theory ; and, if one may judge from the comfortable independency which the person above alluded to is possessed of, through a perseverance, by his father and himself, in this course of management, it is eligible in practice.

" Warwickshire, almost throughout, comes under the description of a dairy county ; and, in the district of the station, the dairy forms a considerable branch of the business of almost every farm. The outlines of practice are, therefore, requisite to be traced.

" The sizes of dairies, here, are seldom large : fifty cows form the largest in the district : thirty are considered as a large-sized dairy : twenty a middling size.

" In taking a view of the dairy of this district, it will be necessary to separate the three principal branches :

" Calves ; Butter ; Cheese.

" The male calves, except such as are reared for breeding, are, almost invariably fatted.

" Calves are, here, fatted at the tent ; and, in the early part of the season, are kept to a good age. But cheese-making once begun, they are butchered as they drop : at not more, perhaps, than three or four days old ; nor at more, perhaps, than three or four shillings price. The

market, the manufacturing towns and the collieries, of Staffordshire.

"The only circumstance relative to the management of fattening calves, which requires notice, is an expedient used by some individuals, but not, I believe, in universal practice; to make them lie quiet; more especially during a temporary scarcity of milk; which will sometimes take place. In this case, balls, made of wheat flour, and a sufficient quantity of gin to form it into a paste, are given them; three balls, about the size of walnuts, being given about a quarter of an hour after each meal. The effect is, that instead of wasting themselves by incessant bawling, they lie quiet; sleeping a principal part of their time. By a little custom, the calves get fond of these paste balls; eating them freely out of the hand; a proof of their being acceptable to their stomachs. As an expedient, they are evidently eligible; and may be of service to a restless calf; even when milk is plentiful. This, however, by way of intimation.

"The only idea which I met with respecting milk butter, and which is entitled to a place here, is that of doing away the rancidness of turnep butter, and the bitterness of barley straw butter, by a most simple and very rational means. Instead of putting the cream, immediately as it is skimmed off the milk, into the jar or other retaining vessel, it is first poured upon hot water, and, having stood till cool, is skimmed off the water; a new idea: but, I will venture to repeat, a most rational one; though I have not myself had an opportunity of proving it.

"In the same dairy in which the above expedient is used, a method of improving the quality of whey butter is practised. This improvement is effected by scalding each meal of cream, as it is taken off the whey; by hanging it over the fire until scalding hot; being careful not to let it boil. This too, I register as a simple and rational process, and not as one whose efficacy I have proved by my own experience. I register them, however, on an authority which I have no reason to doubt.

"Cheese is the grand object of the Midland dairy. Very considerable quantities are annually made; particularly, as has been observed, in Warwickshire, and in this neighbourhood, where cheese of a very fine quality is not unfrequently produced.

"It will, therefore, be proper to take a general view of the subject; for, although, after the recital of the practices of Gloucestershire and Wiltshire, much important information cannot be expected; yet it is more than probable, some interesting circumstances will arise.

"The particulars which, in this case, require to be noticed, are, soil, herbage, managers, species of cheese, time of making, quality of milk, colouring, running, curd, cheese.

"Of the soils of the best dairy parts of this district, it appears a cool soil is favourable to cheese.

"Nevertheless, I received an idea, here, from a most experienced and intelligent manager, that a very cold weak soil is improper for the dairy: that is to say, a soil may be too cool for the purpose. The cheese it affords, though good in quality, is found deficient in quantity. His own farm being principally of that description of land, he has, during the latter part of his life, made rearing his principal object; considering his dairy merely as being subordinate to that end.

"It remains to be registered, the circumstance of cheese being, not unfrequently, made from new leys; even of the first or second year; while they consist chiefly of red clover, with, perhaps, a mixture of raygrass; yet, from these cultivated grasses, provided trefoil make no part of them, good cheese is made. A fact which dairy farmers, in some districts, would not readily credit.

"A striking instance of the folly of dairymen being inattentive to the business of cheesemaking occurs in this district; where a dairy farmer declares, that, one year, he lost forty pounds, by the mismanagement of his dairy-woman. This led him to an investigation of the business, himself, and this to a sufficient degree of superintendence, to prevent in future a similar loss.

"The only factor's cheese made in this district, is thin cheese of new milk. The size that of single Gloucestershire, or somewhat thicker.

"The cheese vats of this district are merely hoops of ash, with a board bottom. I do not recollect to have seen one instance of turned vats being in use. The dia-

meter about fifteen inches. The depth two inches, more or less.

"The fillet of this district is of wood: a long shaving or splint of ash; an inch or more wide, and an eighth of an inch or more thick; not formed into a hoop, but left open, with the ends tapering thin, and overlapping several inches. The part of the cheese which rises above the vat being gathered up and pinched in this fillet, its lower edge is entered within the vat, and, a broad cheese board being put upon it, sinks down with the upper part of the cheese into the vat. In 1789, tin fillets became prevalent: an admirable improvement. Some care, however, is requisite, it seems, to prevent their rusting.

"For family cheese, more or less skim milk is used; and sometimes, I understand, all skim milk. But this not being conformable to the prevailing custom of the country, the practice is looked upon as sordid, and waste becomes the necessary consequence.

"Leicestershire is, at present, celebrated for its cream cheese, known by the name of Stilton cheese.

"Cream cheese being an article of luxury merely, and a species of produce which cannot become of general utility to agriculture, the art of making it does not come within the plan of this work; I therefore proceed to the manufacturing of milk cheese, agreeably to the practice of the district of the station.

"Where the family is large, it is customary to begin as soon as the cows afford milk enough for a cheese; continuing to make family cheese, until the cows go out to grass. From the beginning of May to the beginning of August, is the time of making what is termed year's cheese: continuing from that time, to the latter end of October, to make what is called the latter weigh; likewise for the factor; and from that time, until the cows go off their milk, make family cheese.

"It is not so customary, here, as in the other cheese countries, to skim a part of the milk from which factor's cheese is made; nevertheless, in some dairies it is practised; the proportion skimmed, varying in different dairies.

"In the ordinary practice of the district, cheese is not coloured. Nevertheless, some few individuals use colouring; and find their advantage in doing it. The produce of one passes, at market, for Warwickshire, that of the other for Gloucestershire cheese; the factors of course will give more for the latter than the former. To the consumers, therefore, this filthy practice owes its prevalence.

"In this district, an instance is mentioned in which a large lump of alum being kept in the cowl, during the time of coagulation, was believed to be efficacious in preventing the cheese from heaving.

"The ordinary heat of the milk 85° to 90°. The time in coagulating, held out as proper, is about an hour; but, in practice, I have seldom or ever found so slow a coagulation.

"In a considerable dairy, where tolerable cheese was made, the practice was to bring the curd in about a quarter of an hour; but not to break it up in less than three quarters; I mention this to shew how many different ways there are of producing cheese of a moderate quality.

"In some large dairies, more particularly, perhaps, under the practice last mentioned, the breaking is done, not with a knife or the hand, but with the churn dash; an admirable thought, so far as expedition is thereby promoted. But, in a cowl of delicate curd, this coarse tool would no doubt be improper.

"The gathering is done, in the usual manner, with the hands and the dish, the whey poured off through a sieve, and the curd rebroken.

"In the present established practice, the curd is not scalded; except in the practice of a few individuals; but generally the cheese. It is observable, however, and to me is very interesting, that the finest dairy of cheeses I saw in this district, was not scalded, either in the curd, or in the cheese.

"Cheese, in the press, having been vatted hard with the hands (or in some few instances, previously squeezed in the press), and having stood about an hour, it is taken out of the press and scalded; by immersing it in water, heated to about 150°, letting the evening's cheeses remain in the scalding liquor all night; and the morning's cheeses, until the water be cold; when they are placed again in the press, in which having remained a few hours, they are (in common practice) taken out; the cloth finally taken off; the

the cheeflings salted; replaced in the press; and, having stood another meal (in the whole two meals) are finally taken out of the press.

"On the shelves, cheefes, here, remain only a few days, with no peculiarity of treatment.

"On the floor, the year's cheefe, or first weigh, is seldom or ever cleaned. The edges of the latter weigh are sometimes scraped; and sometimes only rubbed with a hair-cloth; an admirable utensil in a cheefe chamber."

Mr. Marshall, in his Rural Economy of Norfolk, says,

"In the course of the summer of 1781, I likewise paid considerable attention to the art of making butter; registering at the time of observation, the minutiae of the different processes,

"In the production of good butter, much no doubt depends on soil and herbage; and something, perhaps, on the species of cow: much, nevertheless, depends upon management.

"The different stages of the art are, milking the cow, —setting the milk, —preserving the cream, —churning, —making up the butter for present use, —putting it down for future use.

"Cleanliness is the basis of the whole art. A dairy-maid should not be suffered to sit down under a cow with a pail which a fine lady would scruple to cool her tea in; nor until she has washed the teat of the cow and her own hands: and for this purpose clean water and a cloth should always be at hand.

"A cow should be milked at regular and stated hours; and, if possible, always by the same person: for cows, in general, will not give down their milk so willingly to a stranger as to one with whom they are intimate. The consequence is, the richest and best part of the milk is left behind in the udder, and the cow which is not clean-milked becomes dry prematurely.

"Much depends on the cleanness of the vessel, the degree of heat of the milk when set, and its depth in the vessel.

"In summer it is difficult to set milk to cool: in winter no time should be lost in getting it as soon as possible into the pan or milk-lead. Should it be set too hot in summer, the cream does not rise so smooth and rich, nor in so large a quantity, as when it has been set of a due degree of warmth: it is apt to come up frothy; and does not in this case, prove well in the churn.

"Judicious dairy-women, therefore, in summer, pour their new milk first into a large earthen jar or other vessel, there letting it remain half an hour; or until it be nearly cool, and the froth be sunk; and then putting it into the lead or pan, in which cold water has, until that time, stood.

"If it be set to cool in winter, the cream will not rise so thick as when set immediately from the teat, or has had a little hot water put into the milk; viz. about a pint of water to a gallon of milk, or as much as will make it new-milk warm: that is, ninety to ninety-five degrees.

"The depth of the milk should not exceed two inches: from one to two is a proper depth. If the milk be set too thick, the cream does not rise so freely; nor consequently, in so large a quantity in a given time. If set too shallow, it is difficult to separate the cream from it.

"The great art here lies in keeping the cream free from rankness to a proper age.

"Fresh cream affords a well-flavoured butter; but yields a less quantity than stale cream; it being a received opinion among dairy-women, that age, and a slight degree of sourness in the cream, increases the quantity, without injuring, sensibly, the quality of the butter; but that the smallest degree of rancidity in the cream spoils the flavour of the butter.

"In winter, cream may be easily kept free from any degree of acidity; but, in summer, it requires some care to keep it entirely free from rankness.

"A quantity of cream, though ever so judiciously taken off the milk, will, when put into a vessel, and suffered to stand some time, let fall a greater or smaller quantity of milk.

"It has been discovered that this milk, or dregs of the cream, which subsides at the bottom of the vessel, becomes rancid much sooner than the cream itself; and that, being suffered to remain at the bottom of the vessel, it presently communicates its rancidity to the cream: and further, that if it be permitted to mix again with the cream in the churn,

the butter takes that marbled half-cheese-like appearance under which we too frequently see it.

"Therefore, a judicious dairy-woman never suffers these dregs to remain any length of time under the cream. She has two means of preventing it; namely, repeatedly stirring them together to prevent them from subsiding too frequently; and, when a proper quantity is subsided, pouring off the cream into a fresh vessel, leaving the dregs behind. In summer, a good dairy-woman stirs her cream-jar every time (generally speaking) she goes into the dairy; and shifts it every morning (and in close muggy weather every evening) into a fresh, clean, well-scalded jar, or other vessel.

"To take off the rankness of cream produced from turneps, the Norfolk dairy-women sometimes scald their cream: this however is allowed to lessen its productiveness of butter; and I was told by a lady, whose attention to her dairy entitles her to credit in this case, that putting a quart of boiling water into each pail of milk before it be set, is a more effectual and less wasteful remedy.

"The principal art in churning lies in keeping the cream of a due degree of warmth in the churn; and in giving it a due and regular agitation. Warmth and a rapid motion makes it come quick: coolness, and a gentle motion, brings it slowly. If butter comes too quickly, it is soft and frothy, and soon turns rancid; nor does it part from the butter-milk so freely, nor yields so large a quantity, as when it has been a proper time in churning. If it come too slowly, there is labour lost; besides the butter losing its flavour and texture. From one to two hours is a proper length of time in churning.

"If the weather be hot, the churn ought to be chilled with cold water before the cream be put into it, and should be placed in a cool situation: if cold, scald the churn with boiling water, and endeavour to churn in a warm room. If in either case these be not sufficient, add hot or cold water to the cream during the time of churning.

"If the cream be inclined to get frothy in the churn, open its mouth for a few minutes, to let in the air, and give the froth time to dissipate; and the butter will generally come sooner than it would have done had the agitation been continued: for, while the cream is in a state of frothiness, the butter will not separate. Reversing the motion has sometimes a good effect.

"If the butter come in small particles which are slow in uniting, strain off part of the butter-milk; and the butter in general will sooner gather. Reversing the motion generally gathers the butter quickest.

"When the butter is sufficiently gathered in the churn, which is known by the largeness of the lumps, and the cleanness of the dashers, it is taken out; kneaded in a bowl, or other shallow vessel, to let out the butter-milk; spread thin over the inside of the bowl, and clean cold water poured over it; kneaded, broken, and re-spread in the water; the water poured off; the butter beaten, in large lumps or handfuls of three or four pounds, against the side of the bowl; respread; salted; the salt worked in; re-washed; and re-beaten, until the water come off unfullied; which it will do after two or three washings. It is then broken into pound-lumps; re-beaten against the bowl; and printed, or otherwise made up.

"But before the dairy woman begins to take the butter out of the churn, she first scalds, and then plunges immediately into cold water, every vessel and thing which she is about to make use of; in order to prevent the butter from sticking to them. In summer, when the butter is very soft, it is sometimes necessary to rub them after scalding with salt, which greatly assists the wood in retaining the moisture.

"She also puts her own hands into the hottest water she can bear them in; rubs them with salt; and immediately plunges them into cold water: this she repeats as often as she finds the butter stick to them.

"There is a finishing operation, which is sometimes given in the neighbourhood of the metropolis, and perhaps in some few provincial districts: in general, however, this excellent finish is omitted; either through want of knowledge, or want of industry, or through policy: for its use being to give not only firmness and a wax-like evenness of texture to the butter, but to extract from it entirely the butter-milk and the water in which it has been washed, the quantity is thereby lessened; for so many ounces of milk and water extracted, so many ounces fewer of butter go to market:

market: this however is the best proof of its utility; and butter cannot strictly be said to be marketable, until it has undergone this operation: which is thus performed.

"The bowl or tray being wetted to prevent the butter from sticking to it; and a cheese-cloth strainer or other cloth being washed in clean cold water and wrung as dry as possible; a pound-lump of butter is placed in the bowl; and, with a stroke of the hand proportioned to the stiffness of the butter, is beaten with the cloth, (by a kind of dexterity which can only be acquired by practice) and again beaten flat; the dairy-woman, every three or four strokes, rolling up either one side or the other of the pat, and moving it about in the bowl to prevent its sticking. As the cloth fills with moisture (which it extracts from the butter, and imbibes in the manner of a sponge) it is wrung and re-washed in clean cold water. Each pound of butter requires in cool weather four or five minutes to be beaten thoroughly, but two minutes are at any time of essential service.

"In warm weather it is well to beat it two or three times over; as the coolness of the cloth assists in given firmness to the butter.

"The more pure the butter is when put down, and the more perfectly it is afterwards kept from a communication with the outward air, the longer it will retain a state of perfect sweetness.

"The purity of butter consists in its being free from internal air, moisture, filth, and a rankness of flavour.

"The preservation of butter therefore depends principally on the pasture and the method of making. If the pasture be rank, whether through soil, manure, or herbage, it is generally injudicious to put down butter from it. But if the pasture be sweet, and the cows be properly milked, the milk judiciously set, the cream carefully kept, and properly churned; and the butter well worked up, with an additional quantity of salt, there is little art necessary in putting it up so as to preserve it sweet for several months: nevertheless, the more judiciously it is put down, the longer it will retain its sweetness.

"There are various vessels used for putting down butter. When a length of carriage is necessary, wooden firkins are the safest: glazed earthen-ware, however, is preferable when it can be made use of with safety and convenience: for, out of this, the external air may be entirely secluded.

"The figure or shape of a butter jar should be that of the lower frustum of a cone; namely, wider at the bottom than the top: resembling the standing or upright churn: the top of it being made sufficiently wide to admit of its being filled conveniently; but not wider.

"This form prevents the butter from rising in the jar, and effectually prevents the air from insinuating itself between the jar and the butter; whose natural elasticity presses it, in this case, still closer to the sides of the containing vessel: but, were the form of this reversed, the same propensity of expansion in the butter would separate it from the sides of the jar, so that towards the top, a knife might (as it frequently may) be drawn round between them, and the air of course have free admission.

"The method of putting it down is this:—The butter having lain in pound-lumps twenty-four hours, the dairy-woman takes two or three of the lumps, joins them together, and kneads them in the manner in which paste is kneaded. This brings out a considerable quantity of watery brine; which being poured out of the bowl, the butter is beaten with a cloth as before; and the jar having been previously boiled, or otherwise scalded, and having stood to be perfectly cool and dry, the butter is thrown into it, and kneaded down as close and firm as possible, with the knuckles and the cloth alternately; being careful not to leave any hollow cell or vacuity for the air to lodge in; more particularly round the outsides, between the butter and the jar: and for this purpose, she repeatedly draws her finger round by the sides of the jar; pressing the butter hard, and thereby uniting intimately the jar and butter.

"It is fortunate when the jar can be filled at one churning; but when this cannot be done conveniently, the top is left level; and, when the next churning of butter is added, the surface is raised into inequalities, and the two churnings united into one mass.

"The jar being filled with butter to within two or three inches of the top, it is filled up with brine; made by boiling salt and water (in the proportion of a handful to a pint) ten minutes or a quarter of an hour; straining it in-

to a cooling vessel; and, when perfectly cool, putting it upon the butter, about one and a half or two inches thick. If a wooden bung be put upon this, and a bladder tied over the mouth of the jar, butter thus preserved, from a good pasture, will remain perfectly sweet for almost any length of time; provided the jars be placed in a dry and cool situation."

Mr. Marshall, when treating of the dairies in the Vale of Gloucestershire, says;

"The management or immediate superintendence of a large dairy, especially one of which cheese is the principal object, is not a light concern. It requires much thought, and much labour. The whole of the former, and much of the latter, necessarily falls on the immediate superintendant; who, though she may have her assistants, sees or ought to see, herself, to every stage of the business; and perform or ought to perform, the more difficult operations.

"This arduous department is generally undertaken by the mistress of the dairy; especially on middle-sized and small farms. In some cases, an experienced dairy maid is the ostensible manager.

"There are three things principally requisite in the management of a dairy.

"Skill,—industry,—cleanliness.

"Without the first, the two latter may be used in vain; and a want of the last implies a deficiency in the other two. Cleanliness may indeed be considered as the first qualification of a dairy-woman; for without it, she cannot have a fair claim to either skill or industry.

"With respect to cleanliness, the Gloucestershire dairy-women stand unimpeachable. Judging from the dairies I have seen, they are much above par, in reality; though not so to common appearance. A cheese dairy is a manufactory, a workshop, and is, in truth, a place of hard work. That studied outward neatness which is to be seen in the show dairies of different districts, and may be in character where butter is the only object, would be superfluous in a cheese dairy. If the room, the utensils, the dairy-woman, and her assistants be sufficiently clean to give perfect sweetness to the produce, no matter for the colour, or the arrangement. The scouring wisp gives an outward fairness; but is frequently an enemy to real cleanliness. The scalding brush, only, can give the requisite sweetness: and I have seen it no where more diligently used than in Gloucestershire.

"Cleanliness implies industry. A Gloucestershire dairy-woman is at hard work from four o'clock in the morning until bed time.

"Her degree of skill requires not to be spoken of here; as it will better appear in the following detail, than in any general observations which can be made upon it.

"The chief peculiarity observable in a Gloucestershire dairy-room, provincially dairy-house, is that of its generally having an outer door, opening into a small yard or garden place; while the dairy of most other districts is cooped up in a corner, with only a small window for the admission of air and light; every thing being dragged, in and out, through a number of inner doors, or perhaps rooms or passages. But an outer door gives a freer and a more general air; and a much better and a more commodious light; besides rendering the business of cleanliness more easy. In the dairy-yard there is, or ought to be, a well; with proper benches and other conveniences, for washing and drying utensils.

"The room, too, is large and commodious: 15 feet by 18 may be considered as a middle-sized dairy. The cheese-making and churning are done in the dairy-house: so that the entire business is collected into as narrow a compass as may be: a circumstance of some importance, in a large dairy; and, in a small one, the advantages are proportional. The floor is generally laid with stone. The shelves are mostly of elm, or ash.

"With respect to aspect, the outer door, when well placed, opens near the north-east or the north-west corner: the window on the north side: the inner door, on the south-side, opening into the kitchen.

"A dairy-room on this plan is, perhaps, as commodious as art can render it.

"A detail of the furniture of a dairy may appear uninteresting; and, by some readers, be thought unnecessary. It would be difficult, however, to give a minute account of the method of carrying on the manufacture, without describing the tools in use: a description of them is little more than a definition of technical terms. Perspicuity requires it."

"A

"A milking pail is in shape nearly that of a bushel, but formed of staves and hoops; with one handle stave rising three or four inches above the rim. (The Yorkshire skeel with one handle.) The diameter about fifteen inches; the depth about ten inches. Staves oak; hoops (broad and close) ash.

"A milk cooler, provincially cheese cowl, is a large strong wooden vessel, proportioned in size to the number of cows. From eighteen inches, to two feet deep; and from two to three feet diameter. Two opposite staves rise above the rest; the head of each having a hole in it, large enough to admit a pole; for the purpose of moving it, or carrying it on men's shoulders; answering the purpose, occasionally, of what in some districts is called a bearing tub; in others a cowl.

"The strainer, or milk sieve, is made twelve or fourteen inches diameter: five or six inches deep: some with hair bottoms: others have cloth bottoms; which are taken out every day to wash. A frond or leaf of fern is frequently placed at the bottom of the sieve to prevent the milk from flying over.

"Sieve holder; provincially cheese ladder. This is laid across the cooler to place the milk sieve or strainer upon. It has here a valuable singularity of construction: at one end are two cross bars about three inches apart. This vacancy admitting one ear or handle of the cooler, the ladder is kept securely in its place. The wood, ash.

"Lading dish. The usual shape, but large; near a foot diameter.

"Pail brushes. Common hard brushes; furnished with bristles at the end, to clean out the angles of the vessels more effectually. Utensils, or rather tools, which no dairy ought to be without. Yet in many districts of the kingdom their uses are unknown.

"Pail-stake. A simple contrivance, or rather a thought, which one would imagine, no person, having dairy utensils to dry, could miss; yet it appears to have been hit upon in this country only. In other districts I see milking pails, &c. placed upon benches, or upon walls, to dry; where they are liable to be blown down by the wind, or thrown down and burst by other means. Here, a bough, furnished with many branchlets, is fixed with its butt-end in the ground, in the dairy yard. The branchlets being lopped, of a due length, each stump becomes a peg to hang a pail upon or other utensil.

"Skeels, are broad shallow vessels; principally for the purpose of setting milk in, to stand for cream: made in the tub manner, with staves and hoops, and two stave handles: of various sizes, from eighteen inches to two feet and a half diameter; and from five to seven inches deep. Staves oak; hoops (broad and close) ash.

"Skimming dishes are of wood, very thin. But chiefly of tin. About eight inches diameter; and five eighths of an inch deep.

"Cream slice, is a wooden knife, somewhat in the shape of a table knife. Length, twelve or fourteen inches.

"Upright and barrel churns are in use. The barrel churn with one fixt and one loose handle. No way excellent in their construction. Butter is here a secondary object. The Yorkshire churn is preferable: but this might be expected: there butter is the primary object of the dairy.

"Butter board, and trowel, is a broad board and a wooden spatula, used in printing the butter.

"Cheese knife, is a wooden handle, four or five inches long, furnished with two, or three iron blades, twelve inches long, and one inch broad, at the handle, down to about three quarters of an inch at the point; with two blunt edges, rounded at the point like an ivory paper-knife. The distance between the blades, which are very thin, and ranged with their flat sides toward each other, about an inch.

"Cheese vats, are from fifteen to fifteen and a half inches diameter; and from one and a half inch to two inches deep. The wood invariably elm. Some with, but many without holes.

"Cheese cloths we made of thin gauze-like linen cloth. The size varies in different dairies.

"The construction of cheese-presses are various. Sometimes single; but, in large dairies, generally double. The pressure is mostly given by a dead weight, raised by a roller, and falling perpendicularly on the cheese. In the Upper Vale, they are chiefly of stone. The dimensions of one of a superior weight are twenty-two inches square, by two

feet two inches long; containing 12,584 cubical inches of freestone; weighing (on the supposition, that its specific gravity is an ounce and a half to an inch) somewhat more than half a ton.

"But, by an accurate experiment, I found, that a cubical inch of similar stone (freestone of the Cotswold cliffs) weighs only 500 grains. Therefore, calculating the pound averdupois at 7000 grains troy, the stone under notice weighs eight hundred weight.

"The dimensions of other three (all of the same size and in the same dairy) are twenty inches wide; by fourteen deep; and two feet four inches long; containing 7,840 cubical inches of Cotswold freestone; consequently, weigh no more than five hundred weight each.

"These are the old construction; which is very simple. In the center is fixt a wooden skrew, rising three or four feet perpendicularly above the stone; passing through a hole in a cross beam, resting on the cheeks of the press. Above this cross-piece is worked a loose nut, made out of a piece of wood, eighteen inches to two feet long, and of a diameter proportioned to the size of the worm. Each end is reduced to the size of a handle; and with this two-handled nut the stone is raised and lowered. The perpendicularly of the skrew keeps the base of the stone horizontal; and to keep it more steady in its place, it is notched at each end about an inch deep, to admit the cheeks, or slips nailed on the inner sides of them, for that purpose.

"The hours of milking are here early: about five in the morning, and four in the evening; in order to give due time for finishing the requisite business of the dairy, before bed-time.

"Where a large dairy of cows are kept, the whole family (excepting those who have the care of the teams) must attend to milking. An in-door servant, by the name of a milking man, is generally kept, in the larger dairies; for the purpose of milking, churning, and otherwise assisting in the business of the dairy: he has the care of the cows and the cow-grounds; and is considered as a principal servant.

"When the cow-ground lies near the house, the cows are generally brought into the yard, or other small inclosure; if the pasture lie at a distance, the pails are always carried to the cows. Also if the ground be very wet, and poach with the cows travelling over it, judicious dairy-men have the pails carried to them. In more than one instance, I have seen a horse and barrel-cart employed, to take the milk from a distant meadow or cow-ground to the dairy-house.

"The practice is to milk the cows unfettered; and to use square-topped, four-lagged stools; resting one edge of the bottom of the large pail, here in use, against two legs of the stool. Hence the convenience of its form.

"In the Upper Vale, milk butter forms a considerable object of the dairy; not only in the spring, while calves are rearing, before cheese-making commences, but during summer: owing to the species of cheese, which is universally made here; and which, is, I believe, peculiar to the Vale of Gloucester. It is called two-meal cheese. The evening's meal is set for cream; and, being skimmed in the morning, is added to the morning's meal, neat from the cow.

"The method of making butter in this district, therefore, merits a description in detail; especially as Gloucester butter, which is distributed, by hucksters, to distant parts of the country, bears a superior character. The stages of the art are, setting the milk,—preserving the cream—churning,—making up the butter.

"Setting the milk, I have seen done in different ways: every district exhibits good and bad management; in almost every department of rural affairs. The best method of setting milk in this country, which I have seen, and which may, I believe, be called the best practice of the district, is this:

"The milk having remained in the cooler, a time proportioned to the heat of the weather, so as to lower it to about 80 of Fahrenheit's thermometer, it is parcelled out in skeels, or, if these are not sufficiently numerous to receive it, in any other dairy vessel; leaving, perhaps, a part of it in the cooler; dividing it in such a manner, as to leave it about an inch deep, in each vessel: the dairy-woman measuring the depth, by the joint of her finger; and carefully placing the vessel level, so that one side be not left deeper than the other. The prevailing rule is to set it as shallow as it can be conveniently skimmed; under a conviction, that one side be not left deeper than the other;

and that the shallower it is set, the more cream will rise, from a given quantity of milk. An inch and a half is the ordinary depth; but, in the practice I am more particularly registering the dairy-woman has dexterity of finger sufficient to skim it at an inch deep. This, however, could not be done without the assistance of a tin skimming-dish, which being thinner, gathers up the cream cleaner than a wooden one, but requires a more steady hand to guide it.

"Earthen jars are the common receptacles of cream. In these it is stirred several times a day, with the cream slice; but seems to be shifted less frequently here than in some other dairy countries. Cream here has a peculiar propensity to become curdy; losing its liquid state; requiring some strength of hand to stir it; arising probably, from its superior richness.

"In autumn, when butter generally becomes pale and tallow-like, the cream is not unfrequently coloured before it be put into the churn. The material of colouring is the same as that used in the colouring of cheese; which will be spoken of in that article. The method of using it, however, is somewhat different.

"In the practice, which I more particularly attended to, the business of churning is conducted in this manner: if the weather be hot, the churn is previously cooled with cold water; and, if wanted, cold water is likewise put into the churn among the cream. On the contrary, if the weather be cold, the churn is warmed with scalding water; and, if wanted, hot water is put into the churn; which, perhaps, in severe weather, is placed near the fire, during the operation.

"The cream of the Vale is very liable to rise in the churn; owing, probably, to its peculiar richness. Under this circumstance, part of it is taken out; and, when that which is left in the churn is gone down again, the part taken out is re-added.

"The mouth of the churn is secured with butter, pressed plaster-wise into the joints. This is thought to be less troublesome than a cloth.

"The breaking is here carefully attended to. It is considered as very injurious to heat the butter in the churn.

"In making up butter, the first business is to prepare the several utensils employed in the operation. Here they consist of the butter skeel, the butter board, the print, and trowell. The preparation required is to prevent the butter from hanging to the wood. It is here done with scalding water and salt, brushed into the wood while moist and hot, with a soft thick-set brush: either putting the salt upon the brush, or dusting it over the utensil; which, being salted, is immediately plunged into cold water. The dairy-woman's hands are prepared in a similar manner.

"I will give the minutiae of this operation as performed by a most excellent dairy-woman, whose butter seldom fails of being of the first quality. They differ from those which I have already given; and are, probably, the best which I may have an opportunity of observing; and probably the last upon which I may bestow the tediousness of registering.

"The butter being taken out of the churn, and placed in the skeel, with a quantity of cold clear water, the dairy-woman breaks off a lump, (somewhat more than a pound), and, with one hand, kneads it in the water, with the fingers spread widely abroad; closing them at intervals; thereby breaking the butter most effectually; consequently, giving the contained milk an opportunity of escaping. Every time the fingers are closed, the lump is rolled on the bottom of the skeel; the hand shifted, taking the lump the contrary way, and worked as before. This being several times repeated, the first roll is placed upon the butter board, and a fresh lump broken off.

"The whole being gone over in this manner, the milky water is poured out (into the tub of butter-milk), the skeel washed, and somewhat more than half the butter spread thinly and evenly, but roughly, over the bottom of it. Salt is then dusted upon this rough surface; the remaining lumps of butter spread over the salt; and over the whole another portion of salt is strewed.

"The dairy-woman now rolls the whole into one lump; which she immediately breaks down with the palm of her hand; the fingers expanded as before; forcing the butter from her; closing the fingers partially at every stroke; thereby leaving it at the bottom of the skeel exceedingly rough.

"Over this rugged surface fresh water is poured; the

butter rolled up again into one large lump; again broken down in the manner last-described: and again formed into one large roll. This is at length broken into pound lumps; and kneaded in the water, as in the first instance.

"The butter is spread a second time upon the butter board (over which water is always thrown before the lumps be placed upon it), and the skeel being emptied of the briney water, the lumps are separately kneaded (with one hand) on the bottom of it, dry; and set in short rolls, against the side of the skeel.

"The butter scales are then taken out of the salt water, which was poured out of the skeel, and in which they have been immersed during the last operation, and evenly balanced with butter; the lumps divided; and weighed in half-pound pieces; which are again returned into the skeel; or, for want of room, are placed upon the board.

"This being effected, the lumps are prepared for printing; by kneading them, dry, at the bottom of the skeel; and moulding each into a conical form, with the palm of the hand; and with the fingers joined, and set at right angle to the palm. The point of the cone-like lump thus formed, being placed in the center of the print, the base is pressed down, until the surface of the print be covered. What presses over, at the edges, is collected, (by running the finger round the print,) and put upon the intended bottom of the pat. The sides are finally smoothed with the trowel; the pat with the print set upon the butter board; and the print taken off: leaving the pat about four inches diameter, and about one and a half inch thick.

"If the print does not loose freely, the hand is placed carefully and firmly, against the side of the pat; thereby gaining a degree of purchase to pull against. If the butter be found to adhere in any degree to the wood, the print is scalded, salted and brushed, until it loosen freely; without the indelicacy of blowing in the manner practised in most places. The pats remain some length of time, generally one night, upon the board to stiffen; and, in the morning, are placed in cold water, previous to their being put into the baskets, in which they are carried to market.

"The dairy-rooms of North Wiltshire are spacious and commodious. Set round with presses and whey leads: no shelves: the area being left free for the cows, churns, &c. The floors of stone.

"One for forty cows, measured 20 by 16. One for a hundred, 30 by 40; besides a back lean-to for whey leads, &c.

"Whey leads here, have a peculiarity which is noticeable. Instead of a pin or plug being made use of to stop the outlet pipe in the bottom of the lead, the pipe is furnished with a common turn-cock; and in some cases, I was told, the pipes are continued from the leads to the cistern or general reservoir; thereby saving the labour of carrying out the whey in pails. But quere, may not the whey in this case corrode the pipes and be injurious to the hogs?

"Cleanliness is seen in every dairy: a degree of neatness is observable in some. Every thing is conducted in a superior style. There are men of independency and spirit who set the example. Mr. Iles' dairy-room and cheese-lofts form an exhibition worth going some miles to see.

"The North Wiltshire dairy-rooms, in general, have outer doors, frequently opening under a penthouse or open lean-to shed: a good convenience, affording shade and shelter, and giving a degree of coolness to the dairy-room. In one instance, I observed two doors: a common close-boarded door on the inside; and an open-paled gate-like door on the outside: giving a free admission of air, in close warm weather; and, at the same time, being a guard against dogs and poultry. A convenience, which would be an improvement to any dairy-room in the summer season.

"The utensils are similar to those of Gloucestershire. The weight of the press is a box filled with sand or gravel. The dimensions of one, filled with sand, was 18 inches square, by two feet two inches long, on the inside (measuring the depth of sand only). A cubical inch of the sand, when dry, weighs 368 grains; consequently, the whole weight of sand is not quite four hundred weight.

"The broad vats the same dimension as those of Gloucestershire: namely, 15½ diameter. The loaf vats 10 to 12 inches diameter, by four to six inches deep. The vats are mostly without holes in their bottoms, that they may retain the brine the longer.

"It is observable, that the pail of the Avon quarter is the large one-handled pail of Gloucestershire; while, about Swindon,

Swindon, the common pail of the southern counties (iron hooped, with an iron bow) is universally in use; carried on yokes, in the London manner.

"The cowl is proportioned to the size of the dairy. I measured one near four feet diameter: yet this is sometimes too small to contain the milk of the dairy. In this case, two cowls are used; and, when part of the whey is laded off, the two parcels of curd are mixt and broken together.

"The hours of milking are very early. In the morning, the cows are generally in the yards by four o'clock; in the afternoon, by three. In some dairies, and in the middle of summer, the cows are in the yard, and the whole family up, by three in the morning: thus dividing the two meals equally.

"The number of milkers are proportioned to the number of cows; ten cows to a milker is the general allowance. In large dairies, the principal part of the milkers are labourers, or their wives, or daughters.

"The cows are milked promiscuously, and only once over at a meal; not stroked or drawn a second time, as they are in many districts: a practice which I have not observed either in Gloucestershire or Wiltshire.

"Whey-butter. It is the invariable practice in the district of the Vale of Gloucester to set whey for cream. The lower class of people eat scarcely any other than whey butter. With proper cleanliness and management it may be made perfectly palatable, and in every respect preferable (while quite fresh) to some lean-soiled districts. The whey is, here, generally set in one large tub; not parcelled out, thin, like milk. The management of whey-butter is similar to that of milk-butter. The price about two thirds of that of milk-butter in the same market."

DAISY, the greater, or *ox-eye*, by some called *maudlin-wort*, is the name of a perennial weed common in pastures. The leaves are jagged, and embrace the stalk. The flowers are large and radiated. The ray is white, and the disk yellow: the seeds have no down.

DALLOP, a tuft, or clump.

DAM, a mole, or bank to confine water.

DAMSON, a small black plum, brought originally from Damascus; whence the name.

DANDELION, the name of a very troublesome and well-known weed in the meadows; and which will spread greatly, if the flowers are suffered to perfect their seeds, which are light, downy, and of course easily blown about by the wind.

DANERWORK, a name given in some counties to that species of elder, generally called dwarf-elder, or wall-wort.

DANK, damp, humid, moist, wet.

DAPPLE, marked with various colours.

DARNEL. See COCKLE.

Annual DARNEL-GRASS, called *white darnel* by Gerrard, and, in the southern counties, *crap*. This plant is so much like the red darnel-grass, that it has been greatly cultivated under the name of *ray-grass*, or vulgarly *rye-grass*; but the spike is much longer and paler, and has beards, which the ray-grass is entirely without. It is likewise annual; whereas the ray-grass has an abiding root. Its seeds ripen with the corn. See Plate VII. fig. 1.

DAY-BREAK, the dawn, the first appearance of light.

DAY-WORK, work imposed by the day. Day labour.

DEARTH, scarcity; a time when food is dear.

DECEMBER, the last month of the year.

The earth is now commonly locked up under its frozen coat, so that the husbandman has leisure to fit and spend what store he has before-hand provided.

Now is the time to house old cattle, to sell all sorts of timber, and other trees for building, or utensils, to cut coppices, &c.

Let horses blood, fatten swine, and kill them. Destroy ant-hills.

Plough up your land that you design for beans, provided it be not frozen too hard; drain corn-fields where the water stagnates and overflow, or water your meadows.

Put your sheep and swine to the pease-rick, and fatten them for the market. Cut hedges, and lop trees. Mortimer's Husbandry, vol. II. p. 448.

DECIDUOUS, falling, not perennial; an epithet applied to such trees and shrubs as shed their leaves in the autumn. Thus the oak, the elm, the beech, &c. are called deciduous trees.

DECLIVITY, inclination or declivity, reckoned downwards; gradual descent.

DEFECATION, the act of purifying any liquor from its lees or foulness.

DELVING, digging, or the act of turning up the earth with a spade.

DEMAIN, or DEMESNE, the land which a man holds originally of himself. It is also sometimes used as a distinction between those lands which the lord of the manor hath in his own hands, or in the hands of his lessee, and such other lands appertaining to the said manor as belong to free or copyholders.

DENSHIRING. See the article BURN-BAKING.

DEVIL in a bush, or fennel-flower, a very troublesome weed among the corn, especially in Italy, France, and Germany, where it abounds much more than in this country. It rises with slender stalks, near a foot high, which sometimes branch out at the bottom, and sometimes are single, garnished with a very few fine cut leaves, somewhat like those of dill. Its flower is generally blue, and its seeds are rough and black. This, together with their being nearly of the same size as the grains of wheat, renders it difficult to separate them from the corn, when the plant has been cut and housed with it; they blacken the meal, and debase its value. The plant is annual, and therefore may be extirpated by rooting it out before it can seed, which is commonly in August.

DEVIL'S-BIT, the name of a weed often found among the corn, but more frequently in meadows. It has a strong, thick, fibrous, perennial root, which runs deep into the ground, and sends out several branching stalks, which rise near three feet high. The lower leaves are sometimes almost entire, and at others they are cut into many segments almost to the mid-rib: they are seven or eight inches long, and from three or four broad in the middle, hairy, and sit close to the root. The stalks are covered with stiff, prickly hairs, and garnished with smaller leaves at each joint. The flowers, are of a pale purple colour, and have a faint odour, appear in June upon naked foot-stalks at the end of the branches, which decay to the root every autumn.

DEVIL'S-GUTS, the same with the lesser bind-weed. See the article BIND-WEED.

DEVONSHIRING. See the article BURN-BAKING.

DEW, the moisture perceived on the ground, and on the leaves of plants, blades of grass, &c. in the morning.

Those who have made no other reflections on dew than such as present themselves naturally, think that all the moisture one finds in the morning on plants and upon the ground, comes in reality from above; but when the affair is examined with more attention, one sees that at least a great part of the dew arises from the earth itself, and the plants, and keeps hanging to their surface. Mr. Gersten, who hath made a dissertation on this subject in particular, hath even thought that there fell no dew from above on the ground, and that all which we see under the form of dew arose from the earth or plants, on which it keeps hanging in pearls, till the heat of the day hath dispersed it.

For the nature and properties of dew, with regard to vegetation, see the article ATMOSPHERE.

DEWLAP, the flesh that hangs down from the throat of oxen.

DIABETES, a morbid copiousness of urine, or the making water in too great quantities. This disorder is very common in horses, and often terminates in death.

Horses subject to a diabetes, or profuse staling, if old, or of a weak constitution, are seldom cured; they soon lose their flesh and appetite, grow feeble, their coat staling, and they die rotten. Of a young horse there are more hopes; but he must not be indulged with too much water or moist food. At the same time give him the following drink:

Take jesuit's bark, four ounces; bistort and tormentil root, of each two ounces: boil them in two gallons of lime-water to the consumption of half; and give a pint three times a day.

Let the horse drink two or three quarts a day of lime-water; and if these medicines should not succeed, give a quart of strong alum posset, three or four times a day.

This method is proper also for a horse who stales blood; or the following balls may be given for that purpose, if the bleeding is profuse:

Take bole ammoniac one ounce, Japan earth half an ounce, roach alum two drams, elixir of vitriol one dram; make them into a ball with conserve of roses, and give it every six hours.

As this disorder generally proceeds from too violent exercise, over-straining, &c. repeated bleedings in small quantities are absolutely necessary, till the mouths of the vessels close up. *Bartlett's Farriery, p. 165.*

DIAPHRAGM, midriff, or skirt, as some call it, in a horse or bullock, is a muscular substance that divides the upper cavity or chest from the lower belly.

DIBBLE, a setting stick, or instrument to make holes in the ground for setting plants, &c. See **ROLLER** for **DIBBLING ROLLER**.

DIG, a mattock. See **MATTOCK**.

DIGGING, the act of turning up the earth with a spade.

Were labour considerably cheaper in England than it is at present, and a sufficient number of hands could be found, it would doubtless be the best way to dig by hand all the ground destined for potatoes, carrots, lucern, &c. many advantages would accrue from this method of tillage; the earth would be loosened to a greater depth, and much better pulverised; nor would the weeds and grass be so apt to grow as in ploughed lands.

DIGITATED, branched out into divisions like fingers.

DIKE, a ditch. It also signifies a dam or mound to hinder inundations.

DILLS, a species of large vetch, the Yorkshire fitches. See **BEANS**.

DINGLE, a small clough or valley between two steep hills.

DITCH, a trench cut in the ground, usually round the fences of a field.

The mud of ditches affords an excellent manure, as it consists of the putrid particles of animals and vegetables, mixed with the finest and richest mould; and therefore is of great improvement to any soil, particularly the light and dry. But this mud should be exposed to the air for some time, that the seeds of the weeds generally contained in it may have time to vegetate or putrefy, before it be laid on the land.

Ditches on hill sides should be made to face up-hill, especially where the subsoil is springy: for if the springs work through under the bank, they soon undermine and let down the face, together with the layer into the ditch. The outside of the ditch is of much less consequence. The ditches, in every part of the Vale of Gloucestershire, are shamefully neglected. A Vale district, without deep, clean ditches, reflects disgrace on the owners, as well as the occupiers of the lands. In a district, that, by natural situation, is too cold and moist, every possible means ought to be used to free it from surface water; which, if it stand only an hour upon the soil, or in immediate contact with it, adds more or less to its natural coldness. *Marshall's Rural Economy of Gloucestershire.*

DOCK, the name of a weed, of which there are several species, and all of them remarkable for the largeness of their leaves; so that he must be a very slovenly farmer who suffers any of these plants to grow large. They should be plucked up by the roots as soon as they appear, which may easily be done, as the roots are of the tap, or carrot kind.

Mr. Marshall, in his *Rural Economy of Yorkshire*, (vol. I. p. 366.) says of this weed as follows: "It matures its seeds quickly, and in great abundance; but they have no wings to scatter them at a distance; they fall at the foot of the plant. This renders a creeping root unnecessary. Nature's chief care seems to have been to establish the parent plant firmly in the soil, and to guard against its destruction.

"To this end it is furnished with a very strong perennial tap-root of singular properties. If divided below the crown, the part left in the ground sends forth sappling shoots; and this from almost any depth, provided it have head-room, or the soil be loose. The upper part too, if cut off a few inches deep, will survive the amputation. Even when inverted with the plow, it will recoil, and find its way to the surface again.

"In this case, therefore, the plow alone is an improper implement of destruction. On the contrary, it may, and frequently does, increase the number of plants; the part cut off, and the part left below the plough, both of them surviving the separation.

"Hence it is evident, that land which is infected with docks should be gone over with the drawing-iron or the spade, some time before the plough be put into it, that the

tops may be removed, and the rootlets left in the ground may have time to rot before the land be ploughed.

"With this precaution, and with a person to follow the plough with a spadlet to grub up the bottoms, and to disengage the tops of such as may have escaped the previous weeding, the roots of docks may with great certainty be got rid of.

"The seeds of docks are to be destroyed in the same manner as those of other weeds; namely, with the plough, the harrow, and the roller; with this difference, however, that in destroying the seedlings of the docks, or any other strong-rooted perennial plant, the intervals between the ploughings should be short; for if they once get themselves established in the soil, it is, without a favourable season, out of the power of tillage to extirpate them.

"Another precaution with respect to the seeds of docks is necessary: they are sometimes sown upon the land with corn, and very frequently with clover.

"From corn and pulse they may be separated with the skreen, and still more effectually with the sieve; and no man can, in common prudence, sow any species of these until the seeds of weeds have been separated with the utmost care.

"But from clover seed, the seeds of docks cannot easily be separated: they are nearly of the same size and the same weight: neither the sieve nor the fan can part them. Singular caution therefore ought to be had in the purchasing of this seed.

"If every man would be cautious in this matter, the grower of that article would be assiduous in weeding their feed-clover from this pernicious and disgraceful weed. To suffer one dock which has matured its seed, to be threshed with feed-clover, is a crime which ought, among farmers, to be deemed unpardonable."

DOCKING, the act of cutting off the tails of horses.

This operation is in general very successfully executed, by the common methods, which are known to every farrier. But sometimes a miscarriage ensues by an inflammation and gangrene succeeding. These accidents probably arises from the tendons of the tails suffering by an injudicious application of the knife or searing iron, or in an improper season for the operation. Neither the very hot or cold months are proper, for reasons sufficiently obvious. The operation should always be performed by incision, or the chopping engine; the knife being passed through the tail from above, whilst it lays on the block; for when the cutting instrument is applied underneath, the blow is given on the tail, which, by bruising the tendons, may be naturally suspected to occasion bad symptoms. The searing iron should be smooth, and better polished than those generally used, and ought to be rubbed clean with a woollen-cloth, before it be applied to the stump; otherwise the sparks, which fly from the iron, are apt to occasion great pain, attended with the swelling both of the sheath and fundament: nor should it ever be applied flaming hot, for then it brings the burnt part away with it, and requires a re-application, in order to form a fresh eschar on the vessels; by which means, the bone is frequently left too much exposed, so that it is often a considerable time before it is covered.

Farriers seldom apply any thing to the stump; which need only be anointed with the wound ointment, and when the eschar is digested off, may be washed with alum or lime-water: but if an inflammation ensues, with a discharge of thin matter, a proper digestive, composed of Venice-turpentine, rubbed with the yolk of an egg and tincture of myrrh, should be applied, with a poultice of bread and milk over it. The rump should be frequently bathed with oil of roses and vinegar, and a large quantity of blood taken away. If the fundament be at all swelled, and the inflammation at all suspected to be communicated to the bowels, let cooling emollient clysters be injected two or three times a day. Should a gangrene ensue, add *Ægyptiacum* to your dressings, and spirits to the fomentation; and apply over all, the strong-beer poultice, with London treacle, twice a day. *Bartlett's Farriery, p. 323.*

DODDED SHEEP, sheep without horns.

DODDER, the name of so remarkable a plant, that it cannot easily be mistaken. It is entirely without leaves, and does not depend upon the ground for nourishment; but when it is grown up, rots at the bottom, and lives upon the juices of other plants which it entwines itself, by means of threads of a red colour, which it throws out. The slow-

FENCES

ers are small, and come out in roundish heads or bunches, many of them together, here and there, from the stem. *See* BIND-WEED.

DODMAN, a name given in some of the northern counties to the shell-snail.

DODRED *Wheat*, red wheat without beards.

DOG's-Grass. *See* COUCH-GRASS.

DOKE, a deep furrow.

DOLE, or *Dool*, a long narrow green in an arable field, left unploughed.

DOLPHIN-Fly, the name of an insect very destructive to beans. *See* the article BEANS.

DOOL, the same with dole. *See* DOLE.

DOSOME, an epithet applied to such beasts as improve apace. Thus a thriving beast is called, in the northern counties, a dosome beast.

DRAGS, a name given in some counties to the heaviest pair of ox-harrows.

DRAFFE, the grains of malt.

DRAIN, a channel, or trench, cut in the earth, in order to carry or drain off the water. *See* the articles BOG, MARSH, and MOOR.

When coarse grass is produced, the ground is evidently overcharged with moisture, proceeding either from cold, hungry springs, loaded with some mineral or acid, which want vent; or else from external floods, which, being confined by a stiff clay, impervious to water, remain upon it, and corrupt the natural nourishment proper for producing the sweet and richer grasses. When this last is the case, the remedy is easy, by making proper drains to carry off the superfluous moisture. But if the land be spouty or spewy, as it is commonly termed, and the moisture arises from springs, a deep drain must be cut in the lowest part, and smaller drains from that principal ditch to such places as appear to be the heads of the springs, which will be known by their being wetter and looser than other parts. The drains must be cut deep enough to reach the bed, whether gravel or sand, through which the water flows; and upon the first touching of this, the water will be found to run off more freely, and in greater quantity.

The smaller drains, communicating with the main ditch, should be left open for some time, until the quantity of moisture abates. After this, to make them covered drains, by which the surface is rendered level, and no part of it is lost, they should be filled up with small stones to within about a foot and a half of the surface, and then covered with turf, the green side downwards, or with heath, broom, straw, or any other thing that can most conveniently be had, proper to keep the earth from falling in among the chinks of the stones, through which, if no such accident happen, the water will pass easily, the drains will prove effectual, and the plough, after the earth that was turned out is laid above all, will go freely over, without being opposed by the stones. A foot depth of mould over the drain will be sufficient in pasture-ground; but this covering should be at least a foot and a half thick in ploughed lands. Where stones are scarce, faggots made of the branches of any kind of trees are substituted in their place: but they do not answer the purpose so well, because they decay and rot, the earth falls in, and the drains are stopped; though it is highly proper, where these are used, to line the sides of the drains with brick or stone, without mortar, to keep the earth from falling in there, and at the same time give free admittance to the water. It must be observed, that, where a great quantity of water is to be discharged, the main drain into which the smaller drains are to empty themselves, should not by any means be filled up, even with stones, unless it be both very deep and very wide, and there be a great quantity of stones to throw into it, lest it should not be able to discharge all the water; in which case the whole work will prove worse than useless; a remedy being very difficult, on account of the stones.

The best time of covering these drains is about Michaelmas, because the earth is driest at that season, before the winter rains begin to fall. The digging of them indeed is very laborious work, particularly in marshes, the soil of which is always of a tough strong quality. It is therefore of great importance, that every means be used to lessen that fatiguing labour. The shovels and spades universally used are certainly too short. Their length should be such as to give the labourer every advantage arising from his own strength. In order to have this, he should stand as erect as possible; for otherwise, he has not only the weight of the earth on the spade or shovel to raise, but

also that of his own body; whereas, if the shovel be of a due length, an easy shifting of the lowermost hand becomes a prop, or point, on which the weight at the end is raised, almost without bending the body.

Where the ground in which the springs are, lies on a gentle declivity, Mr. Tull very properly advises ploughing it nearly horizontally, by which means each furrow carries off the water, which would otherwise sink into the next ridge. If the clay underneath be at so small a depth that the plough can reach it, this will have a very good effect: and as the nearly horizontal direction of the furrow gives the water but a slow motion, it will not be so apt to wash away the richer mould, as it would if the furrows were more perpendicular to the declivity. These furrows should, however, have slope enough to give the water a current sufficient to prevent its soaking into the ridge underneath.

If the springs rise only at the bottom of a sloping ground, one large drain, reaching the whole length of the declivity, and cut down to the bed of clay underneath, may be sufficient, with the help of a channel, to carry off the water.

If there is any mineral in the earth, especially a chalybeate, which Dr. Home has experienced to be very prejudicial to vegetation, such mineral, being washed out by the springs, is lodged in the soil, towards the surface.

DRAINING of Land, the operation of carrying off the water from wet lands. *See* the articles BOG, MARSH-MOOR.

A correspondent of the editors of the *Museum Rusticum* has obliged the public with the following observations on the uses of draining:

"The first experiment," says he, "I made, was upon a piece of ground of about four or five acres, in the front of my house, of the springy kind; where the waters, collected from the rains and dews in a large plain of dry land above, broke out upon the declivity of the hill, and not having proper drains and channels to carry them away, had, by long overflowing, rendered the ground so soft and boggy, as not to allow the tread of any sort of cattle, (unless in very severe frosts,) and thereby made it entirely useless, and also very disagreeable to the eye. I took the opportunity of a very hard and lasting frost, to carry on a large quantity of stones for making the intended drains, which were laid out in the following manner: A main drain, or trench, was made through the middle of the ground from a small rivulet (into which it was to empty itself) to a little above where the springs made their first appearance: from thence two drains (one on each side) were carried along the side of a hill to the two extreme parts of the ground, emptying themselves into the head of the first mentioned drain, which was only made about three feet deep, till near the top of it. The branches or side drains were better than six feet, as I hoped thereby to have cut off all the springs: but the declivity of the land being considerable, I was obliged to add two drains more below, as some of the springs had escaped under the bottoms of the highest branches. I made the drains in the following manner: the bottoms were flagged with a thin tender stone (of no other use); the sides walled with rubbish stone (the walls being about five inches asunder, and five inches high); and the tops covered with a stronger kind of rubbish stone. Upon the covers I laid rushes and reeds (the then only produce of the ground) to prevent any dirt or soil from getting through the openings of them into the drains; and, lastly, I filled them up with the most porous substances, dug out to near the height of the surface.

"I began this work about the end of March, and had finished it about the end of August. I very soon found the good effects of my labour, the ground being grown so hard and solid before the middle of October, that I was able to carry on, with carts, a very large heap of compost, which I had prepared ready for that purpose; consisting of fresh litter from the stables, virgin earth, street dirt, coal-ashes, and lime, well incorporated together by frequent turnings. The next summer most agreeably surprised me with as fine a crop of hay, both in respect of quantity and quality, as any of the neighbouring grounds could boast, (above three loads to the acre); and the aftermath or second crop was full as extraordinary as the first. In order to know the profit of the latter exactly, I hurdled it off in small parcels: and, having taken in cattle by the week, found the profit better than twenty shillings a statute acre. This ground has kept improving ever since; and now affords me three crops every year; viz. spring pasture for my milch cows

and early feeders, a most plentiful crop of good hay, and an excellent aftermath; without having had any superinduction bestowed upon it since the first, which is eleven years ago. When stones cannot be conveniently had, the common flat tiles for the bottoms, and the common brick for the sides and covers of the drains, will do very well; and, as bricks are more expeditiously laid than the rubbish-stones, I think they will be full as cheap, if proper clay, and fuel for burning them, can be procured upon easy terms. The expence of draining this piece of ground was about five pounds per acre. I have drained many acres of the same kind of land since, with equal success; and at a much less expence. Another kind of land, which has fallen within my practice of draining, is what I call the four spongy land; where there is upon the surface a tolerable good mould, for six or seven inches deep, and below that a stiff clay, that will not permit any water to pass through it; by which means, the soil above is so soaked and chilled, with a constant surcharge of water, that it is not able to produce any thing but rushes, and all the worst species of aquatic weeds. As this kind of land is often nearly level, or but gently declining, the first step I take, is (by levelling) to find the greatest fall I can get within any reasonable distance. Then, by the means of iron-rods, (such as are used in boring for coals) with a bitt or iron scoop at the bottom, I try in several places the depth of the clayey stratum, which so obstructs the passage of the water; and also what the natures of the several strata below it are, till I come as low as the level, where I propose to begin my drain. If I find, in such search, gravel, sand, soft-rock, pinnel, or other porous substance, I begin the good work immediately, and with full assurance of success; making a good stone or brick drain (as before described) through the lowest part of the ground intended to be drained; and then filling it up with the light porous substances, that arise at the digging of it, or any rubbish that can be conveniently procured; taking great care that none of the clay or hard substances be thrown in again; and that the top and sides of the drain be left lower than the rest of the land; that the winter rains may easily descend to it, and so pass (as through a sieve) into the channel prepared to receive them. If there be any low parts in this piece of ground, from whence the rain-water cannot descend to the main drain, small pebble, or wood drains, should be made from those low parts into it; taking care to fill them up with some rubbish or light mould. The clay, which is dug out, may be converted (either by burning or laying up in heaps with quicklime) into a most excellent tillage, either for corn or grass land, for the improvement of the same ground, or any other where it is more wanted. For the fertility of such land, after such draining, is greater than can be well imagined by those who have not tried it, even without any farther improvement. I (generally indeed) set on lime immediately afterwards, if the season of the year be proper for it; which, I say (from experience) is from the middle of April to the middle of July; being certain, (notwithstanding some great authorities, and the common practice are against me), that twenty bushels set upon grass-land, during that season, are more than equal to thirty laid on in the autumn, or winter seasons. About an hundred and sixty bushels to an acre are a proper dressing. The last kind of land, of which I shall now treat, is the black peat or moorish land, many thousand acres of which, in this kingdom, are now entirely useless, though capable of being improved to great advantage. Nay, I will venture to affirm, that there is scarcely any so bad, but that it might, by proper means and due industry, be converted to some useful purpose. For which assertion, I have a happy authority, in that beautiful testimonial of industry, given by Virgil, in his fourth Georgic, to the old Corycian farmer. If these kinds of lands be nearly upon a level, I use the precautions mentioned in the last article; and, if I find my level will carry me below, or to the bottom of this black moorish or peat-earth, I do not regard the depth of my drains, as the digging is very easy, and what is thrown out will nearly pay the expence, by being either dried into peat for fuel, or burnt into ashes; which, if properly managed, are an excellent dressing, either for spring-corn, or grass-land. In the draining of this kind of ground, I make one principal drain through the middle of the piece, (of stone or bricks, as before mentioned), and, at about every eighty or a hundred yards, branches from it. These I make rather better than two feet wide at the top; and continue them nearly of the same width, till within eight or nine inches of the bottom. Then, with a spade

(about nine inches broad at the top, and narrowing down to three inches) I make a lower drain; and, upon the sides or ledges (formed by the narrowing of it), lay large heath-sods, cut square, and exactly to the width of the upper part: by which means, a cavity is left for the water to run in. Upon those sods or covers, I throw brush-wood, or any kind of light trumpery: and lastly, I fill it up with the smallest of the black soil thrown out. Such is the preserving nature of this black peat or earth, to all vegetables buried in it, that there is no doubt but drains of this kind will endure for ever, if they be laid deep enough. After the ground is drained and levelled, marl (if to be had near) should be laid on; if not, sand, gravel, or any kind of light earth. If the first, no other superinduction will be required; but if any of the latter over it should be spread, a cover of some of the finest black mould, that is pretty free from any strings or fibres; and then a compost made of horse-dung, coal-ashes, earth, or clay, and lime; and, lastly, it should be laid down either with grass-seeds alone, or with barley (or oats) and grass-seeds. I laid down a piece (drained and managed as above mentioned) about the beginning of August last, with white clover, yellow clover, and common hay seeds; and though the season was so remarkably dry and hot, yet the young plants came up very well, and very thick, and, in this present severe frost, it affords a verdure not to be seen any where else in the neighbourhood; and the piece is constantly covered by my cattle, tempted by the look, and the sweet food it affords them. I am now preparing about five acres of the same kind of land, to be laid down with barley and grass-seeds in the spring; and hope (if the season proves favourable) to have a good crop of both. I had no marl (or even clay) near, so was obliged to make use of sand and gravel for my first stratum."

DRAINING-PLOUGH, a plough for cutting drains, in order to carry off the water from wet soils.

Several instruments have been invented for performing this necessary operation; but as none were found sufficient to answer the intention of the husbandmen, the Society for the Encouragement of Arts, Manufactures, and Commerce, proposed a premium of fifty guineas for the best plough or machine, of the simplest construction, that should, with the least force, cut a new drain, one foot in depth perpendicular, one foot eight inches wide at the top, and ten inches at bottom; both sides of the drain equally sloping, and the earth to be equally thrown out on both sides. In consequence of this premium, several instruments for effecting this purpose were sent in to the Society; but upon trial one was found much superior to the rest, and answerable to the society's advertisement: and in consequence of which the premium was adjudged to the author.

This plough, of which we have given four figures on Plate VIII. was made by Mr. Cuthbert Clarke, at Belford, in Northumberland; and answered exceedingly well in meadow-ground; but could not be drawn in a stiff clay with the force of eight horses. Fig. 1. is a perspective view of the whole instrument seen on one side. Fig. 2. another view seen in front. Fig. 3. a third view seen at the tail. Fig. 4. a section of the plough, to shew the disposition of the three coulters.

Note. The same letters refer to the same parts in all the four figures; so that where any of the parts cannot be seen in that figure, the letters will not be found.

A, B, C, are the three coulters.

D, E, F, the nuts and screws that fasten the coulters to the beams.

G, H, I, a wheel, or rather roll, which prevents the plough from going deeper in the earth. This roll is divided into three parts, by circular pieces of iron, which project beyond the roll, and cut the turf into three parts. The coulters follow in the same tract, and finish that part of the work.

K, K, the centers on which the roll turns.

L, L, the nut and screws which fasten the iron arbour, in which the pivots of the rolls turn to the beams. These arbours are kept in their proper places by means of the two iron braces f, f.

M, a large iron hook, to which the chain by which the instrument to draw is fastened.

N, the tow chain, or that by which the plough is drawn.

O, the head of the plough into which the beams are mortised.

P, Q, R, the three beams.

M^r Cathbert Clarke's Draining Plough.

I. Barrow delin.

I. Hildett sculp.

S, a shoe of iron, (the whole part from S to A being of that metal) and into which the hoof of the plough is inserted.

T, a shelf on which the mould rises after it is cut up by the coulter and fore-part of the share, till it is thrown out of the trench by the mould-boards.

V, V, the mould-boards, which throw the earth out on each side the trench.

W, W, a band of iron, which fastens the after-part of the plough to the main or middle beam.

X, the head of a tenon, which fastens the mould-boards and hoof of the plough to the main beam.

Z, Z, the two handles, like those of a common plough.

a, b, a piece of board tenoned into the handles, in order to keep the handles in their proper position.

c, d, represents the surface of the ground when the plough is at work. Therefore all the parts below that dotted line are under the ground when the drain is cutting.

f, e, g, shews the angle which the coulters make with a line drawn parallel to the horizontal plane; and is nearly equal to forty-five degrees.

The figures are drawn on a scale of an inch to a foot; but many of the parts, being drawn in perspective, cannot be measured.

We imagine it will be unnecessary to say any thing farther with regard to the manner of working this plough, as the operation is the same as that with the common plough. But it may not be amiss to observe, that the angle f, e, g, being greater than that by which the horses draw upwards, the plough has too great a tendency to get into the earth; the consequence of which is, that, when the soil is very stiff, and consequently requires a very great force to draw the plough, the instrument cannot be held properly by the handles, the force of six men not being sufficient to do this, but the plough will turn entirely over. This was sufficiently apparent to the committee of the Society, at the first experiment, when the ploughs were tried in a stiff clay; for the tail of this very plough could not be kept down by six men at the handles. If therefore the angle f, e, g, were lessened to about thirty-three degrees, this difficulty would, in a great measure, be improved. However, in marshy, boggy, and moory soils, it will answer the intention extremely well, and make a clean trench of the dimensions required by the Society; and therefore cannot fail of being a very valuable acquisition in the practice of agriculture.

DRAINING-UNDER, or *foughing*, is of infinite service in cold and rushy lands. Mr. Marshall in his Rural Economy gives the following method of forming under-drains:

"This trench he sunk six diggings," of about five inches each; making it thirty inches deep, and contracting it to four inches and a half at the bottom: in this instance, hitting the springs, lancing the veins of subterraneous water with great judgment. In filling in this trench, with stones (pebbles picked off ploughed lands—provincially boulders) he began, at the upper end, with a course, about 5 or 6 inches thick; in order that the water, which kept trickling along the bottom, might be stopped and fouled, beginning at the top, bringing down clean water; and having reached the lower end, returned with another course; making the two about eighteen inches deep; each foot in length taking about a cubical foot of stones. The mouth he formed with four bricks, laid in clay, and backed by the largest of the pebbles; leaving a pipe four inches and a half square. The surface of the stones being levelled, they were covered with whole spits or clods of the stiffest of the clay, or strong clayey loam which rose out of the trench; chopping and treading them down close and tight upon the stones; next, filling up the trench, level, with loose mould, and on this placing the first spits, or turf of young grasses; finally spreading the remaining mould thin over the adjoining surface.

Mr. Marshall adds that "under-draining" properly conducted, and in situations where the subsoil is partially too retentive, ranks among the first of rural improvements: it being a fact incontrovertible, that, in the productiveness of lands, more depends on the nature of the subsoil, than on the intrinsic quality of the surface mould.

Land-Ditching, or Hollow Draining, is little attended to out of the counties of Hertford and Essex, where it is practised not only to carry off the water from springy spewy soils, but as a meliorator of stiff loamy clays, such as are so tenacious of rain as to render the land porchy in winter,

and water-bound in spring; those of the first description, it is pretty universally acknowledged, received great improvement by the draining off the water; but those of the latter are not so generally known to receive benefit from the operation of land-ditching. Therefore, would it not be highly beneficial to publish the expence, method, and effects of that great and valuable improvement, when so many rich, though wet counties, are totally ignorant of that operation in husbandry?

The expence and general method is pretty accurately ascertained in the inclosed letter from Mr. Mason.

The engravings of the implements might be published according to the inclosed drawings.

"Drains filled with wood, and covered as usual with straw or rushes, are preferable to stones, or any other kind of material; the reason is, that as the wood decays, the water continues to pass. When filled with stones, and the drain stopp'd up, which must be expected to take place in time, the earth becomes quite solid round the stones, and as they do not decay, the filtering of the water is for ever obstructed; not so when bushes or wood are used; continual filtering and draining are then for ever to be perceived; and by repeating the operation a second time, cutting the drains transversely of the old ones, the benefit of the filterings through the rotten wood is secured, and the spewing up of old, broken, and damaged drains corrected and carried off. Moreover, as bushes form a much greater number of cavities than either stones or poles, they are less able to stop up, and encourages filtering more than larger and more solid bodies.

The general effects are, that the land, after draining, not being so much chilled by the long continuance of the winter-water on the surface, produces earlier vegetation in the spring; the grass is rendered of a better kind; the white clover is encouraged, which seldom fails in Essex and Hertfordshire to chequer the land-ditched fields with its sweet appearance. Tillage-land is rendered much more manageable, it dries gradually and early in the spring; the bad effects of land being catch'd full of water when the parching winds in March suddenly harden the surface of wet grounds, is prevented, and the earth breaks kindly. This in a short time alters the very nature of the soil: the weeds and grasses change their colour; every plant that grows, loses the appearance of rankness; the corn increases in quantity and weight; and every benefit a farmer can wish, is more or less the consequence of this first of all improvements, in proportion as the soil draws well or ill.

DRAPE, a farrow cow, or one whose milk is just dried up.

DRAUGHT horse. A horse destined for the cart, plough, &c. in the choice of which for either of these purposes, being that which they call the slow draught, one is to be chosen of an ordinary height: for horses in a cart, unequally sorted, never draw at ease, but the tail hangs upon the low horse. Our English authors say, he should be big, large-bodied and strong-limbed by nature, rather inclined to crave the whip, than to draw more than is needful; and for this purpose, mares are most profitable, if you have cheap keeping for them; for they will not only do the work, but also bring yearly increase: but care must be taken to have them well forehanded, that is, to have a good head, neck, breast, and shoulders; but for the rest it is not to be regarded, only let her body be large; for the more room a young foal has in its dam's belly, the better: and be sure never to put the draught horses to the saddle, for that alters their pace, and hurts them in their labour. See **PACK-HORSE**.

Some say, that a horse designed for draught or labour, ought

ought to have a head with large bones, and not fleshy, that so he may not be subject to diseased eyes; that his ears ought to be small, straight, and upright, and his nostrils should be large and open, that he may breathe with the more ease and freedom; that those horses that have their foreheads sunk a little downwards about the eyes, are generally good for labour: whereas those who are designed for the saddle, ought to have them even and pretty large; that the forehead should be always marked with a star, unless the horse be of a grey or white colour.

You must see that he has a bright and lively eye, full of fire, and pretty large and forward in his head, having large balls, and raised pits, and never sunk, which shews that the horse is old, or begot by an old stallion; and if he has a bold look it is always a good sign; sunk eyes or elevated brows are indeed signs of some malignity in a horse; but these sort of horses will generally undergo much fatigue.

His mouth should be pretty wide, being a quality very essential to it, the palate not fleshy, and the lips thin: the mouth also should be cool, and full of foam, by which you may discover the good temperament of a horse, and that he is less subject to be heated than another; not that the mouth should be that which must be most regarded in a draught horse; for if he has a bad one he often draws well.

We do not require fine chests in draught-horses, that not being essential; all that is to be said on this occasion is, that such animals ought to be pretty thick and fleshy ones, but his breast should be large and open, his shoulders should be thick, that he may draw the easier, and that his harness may not so soon hurt him: if he be somewhat heavy he is the better for draught; for the more he is nearer to the ground, the more he is valued for that purpose. He ought to have double loins which may be seen by their being a little raised up towards both sides of the back-bone; he ought also to have large and round sides, to the end that he may have the more guts, and a better flank: you need not be afraid of his having a great belly, provided it be not cow-bellied, which will make him appear deformed; he should have full, but not broad flanks, that he may not sway in the back at his labour.

That horse is esteemed which has a large and round buttock, that neither sinks down or cuts: care should be taken that he should have a firm and strong tail, that the dock should be thick, well furnished with hair, and placed neither too high nor too low, both which contribute much to the deformity of the buttocks. The legs are parts of the body of a horse which are most to be considered, as being those which are to support the burthen of the whole body, to which they ought to suit; therefore his legs should be rather flat and broad than round, the roundness of the leg being a defect in a horse destined to labour, which will soon ruin him; as for the hinder legs, the thighs should be long and fleshy, and the muscle that is on the outside of the thighs should be fleshy, large, and very thick: it is a fault to find them fall down plump when the horse steps; it is also a sign of weakness in the loins or hams: however you are not to consider the hind legs so much as the others, they being not so subject to be faulty; the fore ones being very often bad when the others are good. Those horses whose legs are too long and too large for their height, are faulty, and you ought not to buy them. You must always observe that he stands well and plump, when he stops in any place; and if he does not, you may conclude he is not good.

The usual way to know the age of a horse, is by his teeth, eyes, &c. for which the reader is referred to the article of *AGE of a HORSE, EYES of a HORSE, &c.*

The nether jaw of the horse should be examined very well, to see that it be incommoded with no gland, which may occasion the strangles, and be a means to kill him.

Something may be said concerning the feeding of a draught-horse; but for the servant who looks after him, he ought to be up very early, and see that the harness be in good order; and take away the old hay out of the rack, lay fresh in, and clean the manger, ridding it of all ordure, earth, or foul dung; and while the horses are eating their hay, he ought to take them one after another out of the stable, to curry them; for if he should do this work within, the dust will fly to the other horses.

If persons would be persuaded of the necessity there is to dress horses well, they would not be so often surprised at the loss of them, for want of this care, though they feed them ever so well.

It is from the filth that is upon and about them, that ma-

ny of the distempers which befall them have their rise, and prove their destruction; and it may be held for an inviolable maxim, that a horse with less food, methodically dispensed, and well dressed and curried, shall be fatter, and more lightly, than another who has more provender given him, and whose dressing is neglected; and therefore the master of a family ought to be on the watch, and see that his servants (if they are of themselves careless) be not wanting in this particular.

Such sort of servants ought to be good humoured, handy, tractable, nervous, and hardy; and in order to dress a horse well, they should hold the curry-comb in the right hand, and the horse in the left, near the buttock, and lightly move the comb backwards and forwards along his body, and continue so to do till no more filth or dust come off, and then they must, with a dust-cloth, wipe off all the dust that lies on the horse, taking care to do it all over his body.

They should daily, after they have dusted their horses, take a whisp of straw, and twisting the same hard, wet it in water, with which they should rub them all over, more especially the legs: by this means they will remove obstructions, and facilitate the passage of the animal spirits, which cause motion: indeed it cannot be expected this second dressing should be practised every day, but it ought to be done as often as servants have any leisure for it, particularly when the weather does not permit them to labour abroad; and if they are defective therein, the master of the family ought to make them do it. When the horses are thus dressed, the next thing is to take the comb, and gently to comb their manes and tails; and then they are to be led out of the stables to water, and to cheer and divert them as much as possible.

Most part of the diseases to which horses are subject, proceed from their drinking bad waters; such as those that are too vivid, or too raw, muddy, and too cold. To prevent these inconveniences, you must observe, that if you are near a river, you should in summer-time, by all means, lead your horses thither; but as little as may be in the winter, if you have a well near home; for well-water fresh drawn, during the season, is warm and consequently good for the horses: if you are remote from any river, and that in summer-time you have no other than spring-water to give your horses to drink, you must draw the same a good while before it is given them, and expose it to the sun in tubs, or very clean stone-troughs, that you may by that means correct the great crudity of the water, which is extremely injurious to them: you must seldom or never carry them to drink marshy water, which has very bad qualities, and will not agree with them.

When your labouring horses have drank their water, you must give them their oats in a manger, that has been first of all cleaned: the oats should be well sifted and cleared from dust, before you give them; you ought to take care to smell to them, and see if they smell of rats, or are musty, which will make the horses loath them. You must, likewise, above all things, observe whether there are any small feathers among the oats, which may, if left therein, do the horse a great deal of injury: the quantity of oats allowed to each horse is sometimes more and sometimes less, but ever enough to make them keep up their flesh; and while the horses are eating their oats, the servants are to take their breakfasts, and afterwards go to harness them for the plough or cart, as their occasion requires.

But before they do this, they must examine whether any thing hurts them, either at the breast, shoulders or hams; and they must see that the collars about their necks be supplied with every thing that is requisite for them: if they are to draw in a cart, you must see that the pad upon the back does no way hurt them, that the same fits every way even, and that it be well stuffed with hair in the pannels, for fear it should be too hard upon the horse's back.

The horse being thus managed, and every thing in good order for the work, whether with plough or cart, those servants who do understand their business well, do not work them at first too hard, but every turn let them gently breathe; whereas if they do otherwise, they will very often find them decline their food, after their return from labour; by which ill management they sometimes run the danger of foundering, or having their grease melted; and therefore to work them gradually is the best and safest way. When the horses are returned from the plough, &c. as towards noon-tide, or the like, they are usually all in a sweat, and then the men must not fail to rub them with a

Scale of 3 Feet. for Fig 7 & 8.

whisp of straw ; this is the first thing they are to do after they are brought into the stables ; then let them prepare some bran which is very well moistened, which put before them in the manger, to make them mumble the same, and this will make them eat the hay with a greater appetite ; the bran being ordered as before, will cool their mouths, which are dried, through the heat occasioned within by their drawing ; and notwithstanding the horses are thus hot, it is very rarely that any inconvenience happens to them, especially if the water wherein the bran has been steeped, be used rather hot than cold : when such precautions are not taken, it is no wonder the owners and their servants, very often find their horses loath their food ; the dryness of their tongues rendering all the food insipid to them ; and therefore those persons who love their horses, ought carefully to observe this method, and they will find their account in it.

We daily see persons who pretend to be well skilled in the management of horses, as soon after hard labour as they are brought back to the stables, never fail to rub their legs with wisps of straw, alledging that this is the way to refresh them very much ; but they are much mistaken in the point, for the horses after hard labour, must not have their humours much agitated ; and by this action they must needs fall upon their legs, which will tend to make them very stiff and useless. The author adds, that he was willing to give them this information and caution, judging it very necessary for the avoiding those inconveniences which happen daily by that ill method, which cannot be followed after such admonition, but by those who are obstinate in their way, and will ruin their horses : not that our author disapproves the rubbing of their legs, which he says is very wholesome ; but it must not be done when they are too hot ; and they should confine themselves only to the rubbing of their bodies when they are in a sweat, and let their legs alone.

Their racks being well supplied with hay, you must suffer your horses to rest two hours, or thereabouts, or otherwise as above directed ; and then in a little time after they have eaten their oats, to work again with them : in the evening, when your ploughing or other work is over, the first thing to be done after they are tied to the rack, is to lift up their feet, and see if there is any defect in the shoes, and at the same time take out with a knife, the earth and gravel which is lodged in the foot between the shoe, and the sole, and put in some cow-dung : this your servants often neglect, and therefore the master ought to see them do it.

A thing very essential for the preservation of all sorts of horses, is good litter, which to these animals, is comparatively the same as clean sheets to men. There are many who suffer the dung to rot a great while under their horses ; some through laziness, will not clean their stables, and others say they leave the dung there that it may receive more juice, and be the better manure for the ground ; but it is very wrong reasoning, to say we do this to save five shillings, and lose ten : but you are to understand, that the dung being heaped up for a considerable time, does so over-heat the horse's feet, that this alone is enough to ruin them entirely.

Hence also arise so many inconveniencies to the owners of them, that they are often obliged to keep them in the stable without doing any work, which embarrasses either the master to whom they belong, or the servant who has the care to dress them ; and this inconvenience proceeds only from their ignorance of the cause ; and therefore it is of the highest importance, that the stable should be cleansed as often as possible, and the horses have fresh litters given them ; besides, it is natural to believe, that all animals hate their own ordure ; and it is absurd to think, that a horse, which is one of the cleanest among them, should not do the same.

Fresh litter has a virtue to make horses stale as soon as they come into the stable, whereas when they find no such therein, they decline staling ; and if the people were sensible what refreshment it is to a horse to stale at his return from labour, they would be both more curious and careful to let him have that which would promote it, than they are.

This staling after much fatigue, will prevent obstructions in the neck of the bladder, or passage of the urine : but if otherwise, and that this same urine comes to lodge in the bladder, it will cause some inflammations there ; which are very dangerous evils for horses, and of which they very often die, without present relief : hence you may judge of the

necessity there is to let your horses frequently have fresh litter.

As to the remaining care you ought to have of your horses, so that they may pass the night as they ought, there needs no more after you have well rubbed them, than to supply their racks with hay enough, which they may feed upon after they have eaten their oats : and continuing thus daily to manage them, it will be the means to keep them in a condition to do you good service.

DRENCH, physic, &c. given to a brute by means of a horn cut properly for that purpose.

DRESSING meadows. See **MEADOWS**.

DRILL-PLOUGH, an instrument for sowing corn in drills, or rows, which is an essential part of the New Husbandry.

The two first inventions for sowing in this manner, were Mr. Worlidge's drill-plough, and Don Joseph de Lucatello's sembrador, both of which may claim the merit of inventions, and therefore must not be omitted in this work.

" Besides the usual method of sowing corn, there are, says Mr. Worlidge, several other ways of dispersing it, as by setting, and hoeing of it in, &c. This art of setting corn seems to be very ancient, as appears by Virgil, *Unguibus infodiunt et ipsis fruges*. And hath been a long time attempted to be brought into practice again, as appears by Mr. Platt's Adam's Tool revived. Mr. Worlidge then points out the defects in Mr. Platt's instruments, and proceeds thus :

" But to remedy and remove all manner of errors and inconveniencies that can be found in setting of corn, I shall here give you a plain and perfect description of an easy and feasible instrument that shall disperse your corn, grain, or pulse, of what kind soever, at what distance, and in what proportion, you please to design, and that with very great expedition, and very little extraordinary charge, expence, or hazard.

" First make a frame of timber, of about two or three inches square, the breadth of the frame about two feet, the height about eighteen inches, the length about four feet, more or less as you please, as at *u u u u*, fig. 1, Plate IX. Place this frame on two pair of ordinary wheels, like plow-wheels. The axle-tree of the two foremost wheels is to lock on either side, as doth the fore axle-tree of a waggon, for reasons hereafter shewn. The hindermost axle-tree, being of iron, and square in the middle, must be fixed to the center of the wheels, that the axis and wheels may move together : then about the middle of the frame, in the bottom, let there be fixed an iron instrument, or of wood pointed with iron, like unto a coulter, made a little spreading at the bottom, in the nature of a share, made to pass through two mortises on the top, for its greater strength ; and made also to be wedged higher or lower, according as you will have your furrow in depth, as at *o o* ; the use whereof is only to make the furrows : so that you must make the point thereof, of breadth only to move the earth, and cast it, or force it, on either side, that the corn may fall to the bottom of the furrow. Then over this share or coulter, a little behind it, may a wooden pipe be made, to come from the top of the frame to the lower end of the share, tapering downward, as at *p*, and as near as you can to the share ; to deliver the corn immediately, as the ground is opened, and before any earth falls in ; that what earth does afterwards fall in, may fall on the corn. This pipe is to proceed out of a large hopper fixed on the top of the frame, that may contain about a bushel as at *q* : but so that the corn may gradually descend, according to the quantity you intend to bestow on an acre. At the very neck of the hopper, underneath, in the square hollow thereof, must be fitted in the edge of the wheel wood, about half an inch thick, and proportioned to the cavity of the neck, as behind the letter *r*. The wheel need not be above two or three inches diameter, and fixed on an axis extending to one side of the frame to the other : on which axis is also to be another wheel with a groove on the circumference thereof, like the wheel of a spit or jack, as at *s* ; which must answer to another wheel of the like nature and form, fixed on the axis of the hinder most of the wheels, as at *t* : then fit a line (of silk as best, because it will not be so apt to shrink and stretch as hemp) about these two wheels, that when the instrument moves on the hindermost wheels, by the means of the line, the small wheel at the neck of the hopper may also move ; which lesser wheel in the neck of

the hopper, may have short pieces of thick leather fixed in the circumference thereof, like unto the teeth of a jack-wheel, that upon its motion, it may deduce the corn out of the hopper, in what proportion you please: for in case it comes too fast, then you may by a wedge at the tenon of the piece whereupon the hopper rests, as at *t*, or at the end of the axis of the lesser wheel, force the wheel and hopper together; as, in case it feeds too slow, then may you remove them by the same wedges to a farther distance; also in case your line be too slack or too hard, you may prevent either extreme by a wedge in the place where the axis of the wheel moves; or by a third wheel, about the middle of the line, made to move farther or nearer, as you may see cause.

"Also by means of the iron-rod *u v*, fixed to the foremost axis that is made to lock, may you guide your engine at pleasure; which rod is made crooked at the end of the hopper, lest that should injure its motion.

"And at the turning you may lift up your engine by the handles at *x*: for whilst you lift it up, the corn feeds not until you set the same down again.

"One horse and one man may work with this instrument, and sow land as fast or faster than six horses can plough; so that you may with ease compute the expence, in case your instrument be single: but you may in the same frame have two shares at twelve inches distance, more or less, as you will have the rows of corn distant the one from the other; and two pipes out of the same hopper, and two small wheels on the same axis, with other wheels answerable, every whit as easy to be performed as one; and then you may double your proportion of land in a day.

"This instrument will always keep the same proportion you first set to, which you must thus contrive.—First, know the length of the furrow you sow: then call up how many of these furrows at such distance your instrument is made for (whether a foot, more or less) will amount to an acre: then conclude how much to sow on an acre; suppose a bushel: then divide that bushel into so many parts as you have furrows or distances in that acre; then take one or two of those parts, and put into your hopper, and observe whether it will hold out, or super-abound at the end of one or two furrows, and accordingly proceed and rectify the feeder: or you may judge by your own reason, whether it feeds too fast or too slow.

"In case it feeds too fast, notwithstanding they be close placed together, you may make that wheel at the lowest axis, wherein the line moves, to be less than the upper; then will the motion be slower: and thus may you make it move as slow as you will, by augmenting the upper, and diminishing the lower wheels wherein the line is; and make it move faster by the contrary rule.

"In case you drive apace, it feeds apace; in case you drive but slow, it feeds but slowly: here is no error.

"When you come to any turning at the land's end by lifting up the hindermost part of the instrument, that those wheels touch not the ground, the feeding of the corn immediately ceaseth, until you set it down again.

"Also all the corn you sow lies at a certain depth, none too deep, nor any too shallow.

"You may place a kind of harrow to follow; but the best way is to have on each side of each furrow a peice of wood, a little broad at the end, set aslope to force the earth rounding on the corn. This may be well placed and fitted to the bottom of this instrument, just behind the share and feeding pipe.

"By this method of sowing any sort of grain or pulse, may be saved the one half, and in some places more, which by the other way, is either buried so deep under the clods, that it cannot come up, or else it is so shallow, that the cold in the winter, or drought in the summer killeth it, or else lies on the surface as a prey to the fowls of the air: much also therefore falls in clusters, twenty or thirty grains where one or two might suffice, which are common inconveniences, and usually happening to the vulgar way of sowing corn: the greater half by far is lost, which in all probability may be saved by the use of this very instrument, which will doubly requite the extraordinary charge and trouble thereof: for here is no corn sowed under clods, but in rows, as the earth is stirred and moved: it is all at one certain depth, and at one certain distance, and equally covered; below the injury of frost, and heat, and rapine of birds. Also by this way corn may be sown in the very

middle or convenient depth of the mould, that it may have the strength of the land, both below and above the roots; whilst in the other more usual way, the corn falls to the bottom of the furrow on the gravel, clay, or such like hard ground, where it seldom thrives so well as what happens to be in the midst. This way also exceeds the way of setting corn, where the pins thrust into the ground harden and fasten the mould, so that, unless the land be very light, it confines the roots to too narrow a place, which in this way is prevented; as I have observed in garden beans, that those hoed-in proved better than those set with a stick.

"By the use of this instrument also may you cover your grain or pulse with any rich compost you shall prepare for that purpose, either with pigeon-dung dry or granulated, or any other saline or lixivial substance, made dispersible, which may drop after the corn, and prove an excellent improvement: for we find experimentally, that pigeon's-dung sown by the hand on wheat or barley, mightily advantageth it in the common way of husbandry: much more then might we expect this way, where the dung, or such like substance, is all in the same furrow with the corn; whereas, in the other vulgar way, a great part thereof comes not near it.

"It may either be done by having another hopper on the same frame behind that for the corn, wherein the compost may be put, and made to drop successively after the corn: or it may be sown by another instrument to follow the former, which is the better way, and may both disperse the soil, and cover both soil and seed.

"The corn also thus sown in ranges, you may with much more conveniency go between, and either weed it or hoe it and earth it up as you think good, and at harvest it will easily repay the charges.

"Also the fore-wheels being made to lock too and fro on either side, you may have an upright iron pin fixed to the middle of the axis, extended to the top of the frame: and from thence a small rod of iron to come to your hand, with a crooked neck just against the neck of the hopper; by means of which iron rod, you may lock or turn the wheels either way, and guide your instrument, and rectify it, if it deviate out of its right course.

"The hopper must be broad and shallow, that the seed press not much harder when it is full, than when it is near empty, lest it sow not proportionably.

"Though this instrument may at first seem mysterious and intricate to the ignorant, yet I am confident it will answer to every particular of what I have written. Any ingenious wheelwright, joiner, or carpenter, may easily make it, with very little instruction, and any ordinary ploughman may use it."

The chief inconveniences in this instrument seems to be, that the seed is liable to be bruised as it drops from the hopper, by the wheel in the neck of that hopper.

In the account which is given of the sembrador, in the Philosophical Transactions, it is justly observed, that the perfection of agriculture consists in setting the plants at proper distances, in ground well loosened to a sufficient depth, that their roots may be able to spread, in order to collect the nourishment which is necessary to produce and ripen their fruit. But this is so little observed, that almost all sorts of seed are commonly sown by handfuls at random; whence it happens, that corn is sowed too thick in some places, too thin in others, and, frequently, the greater part of it is either not covered at all, or not deep enough; by which means it is not only exposed to be eaten by birds, but also in cold countries to be spoiled by frost, and in hot climates, by the sun. To remedy these inconveniences, Don Joseph de Lucatello invented an instrument, which, being fastened to the tail of the plough, drops the seed regularly in the furrows, saves four parts in five of the quantity which is generally used, and becomes the means of procuring a considerable increase, without employing a person purposely to sow.

As a few words will explain the mechanism of this instrument, which has its merit, though it has not been found to answer in common practice, we shall venture to give the following short description of it; because some of the principles of this may possibly suggest an useful hint to an ingenious artist.

Fig. 2, Plate IX. is a box of wood: *a, b, c, d*, the cover of that part into which the corn is put, and which is open in fig. 3. at *W*: *e, f, g, h, i, k, l*, fig. 2. are the two sides which cover that part of the box where the cylinder, which is fluck round with three rows of little spoons

to throw out the grains, is turned round. These sides are taken off in fig. 3, to shew the cylinder R S, and the spoons *x, x, x*. The internal shape of these sides is expressed in fig. 4, where may be seen the four triangular pieces *p, p, p, p*, and the triangular interstices *q, q, q*, which let it out at the bottom of the box. T, is one of the wheels which turn the cylinder; and V the other end of the cylinder, on which the other wheel is to be fixed. The furrow in which the grain has been dropt is to be covered by the next turn of the plough; to which end the mould board must project considerably.

In using this instrument, according to Don Lucatello's method, it must be fastened to the beam of the plough, at such a height, that the long projecting nails in the wheels may touch the ground sufficiently to make them turn round, but not enough for the wheels to rest upon it, and drag along without turning.

This way of turning the wheels, and consequently the cylinder, must occasion an unequal distribution of the seed, wherever the ground is rough and stony. For this reason, and on account of some other inconveniencies attending the use of it, this sembrador is not an instrument to be recommended to farmers: but we would here refer to the consideration of such as are better skilled in these matters, whether an instrument less liable to this objection, or to the fault which is found in Mr. Worlidge's drill, may not be formed, by placing the seed-box of the sembrador in a frame like that of Mr. Worlidge, with (instead of the wheels of the sembrador, which turn upon the ground) two wheels, grooved like pulleys, fixed upon the axis of the cylinder, to be turned with cords, like the small wheel at the neck of Mr. Worlidge's hopper. A square frame, like that, will keep the box more steady, and therefore render the discharge of the seed more regular, than it can be in Don Lucatello's manner.

Husbandmen have been long sensible, that sowing corn by handfulls, or broad cast, was a waste of seed, and some attempts were made to construct instruments for sowing more regularly; but though the sembrador and Mr. Worlidge's drill were ingenious instruments, it does not appear, that they or any other, answered in practice, till Mr. Tull contrived his drill-plough, which does perform very well. Mr. du Chateaux indeed says, he thought Mr. Tull's too complex, and invented another, which is very ingeniously constructed, but if we may judge from his description of it, it appears to be more complicated than Mr. Tull's, or any other; and being very expensive, is not likely to be introduced into England. It is also too limited in its use, being constructed to drill only three rows, at one certain distance. M. Duhamel's drill, called a barrel drill, is more simple and cheaper, and may be more easily altered to sow more rows, and at different distances, and will probably be offered to the public in a short time, with these improvements.

Mr. Young, in his Essay on the Culture of Cole-seed, complains much of the drill ploughs, on account of their being so weakly constructed. "I used," says he, "Mr. Randall's drill-plough, and in this charge (of expences of the crops) do not include the repairs, which in all my trials have been so great, that it would be absolutely unfair to insert them; and yet it is not altogether the thing, to make no charge of this sort, and especially as I have seen no drill-plough (not excepting those in the society's room) but what would fall in pieces presently, under the rough hands of ploughmen. Common ploughs are every where of a strength proportioned to the hands they go through, and till a drill is discovered that will bear such treatment, it is impossible to promote the new husbandry: nor is it possible that any method should be worth promoting, while the instruments with which it is executed, remain in the predicament of all drill-ploughs at present."

There is indeed some ground for this complaint, but will be removed in a drill-plough now constructing.

M. Duhamel observes, that the drill-plough invented by M. de Chateaux delivers the grain with the greatest exactness, and therefore deserves much commendation; but that the price of it is too great for most farmers. His own, which we shall now describe, has, for that reason, been the most generally used.

M. Duhamel's drill is fastened to the fore-carriage of a common plough. The hind part consists of a plank S S, fig. 5, Plate IX. at least three inches thick, which is called the table. Underneath this table, and to the bottom part of it, are strongly fixed, as at T, T, T, three shares. The beam I, I, is fastened to the fore-part of the

table: and the handles L, L, are let into mortises in the back part of the table, in which they are fixed. *a, a, a*, are these sloped cavities cut in the table, to receive the seed from the cylinder, and convey it through a hole, about an inch in diameter, in the center of each of them, into the hollow *c*, at the back of the share, fig. 6. The form of these cavities is more clearly expressed by *a, a, a*, fig. 7. At *b, b, b, b*, fig. 5, are fixed four strong standards, to hold the drill-box steady.

The shares fig. 6, are made of wood, and terminate at the bottom of their fore-part *a*, in a circular form, covered with iron. In their hind-part *b*, is a groove, through which the seed drops to the bottom of the furrow. The seed is conveyed from the cavities *a, a, a*, fig. 7, to this groove *b*, fig. 6, by means of a thin plate of iron *c*, rounded and fixed to the share, at *d*. These shares are about an inch and a half thick, and their height from *a* to *b* is at least a foot.

As these shares terminate in a curve at bottom, if they meet with any roots, dung not thoroughly rotted, or any other substance which they cannot easily divide, they force it down to the bottom of the furrow, and by that means are never liable to be choaked: and to prevent this still more effectually, the middle share is placed somewhat more shorter, when used in land laid out in ridges, in proportion to the greater height of the middle of the ridges. The shares are generally seven inches asunder.

The four standards *b, b, b, b*, fig. 5 and 7, are placed in such a manner, that the blocks *n, n*, fig. 8, in which a groove is cut, answer to the middle of this table. On an iron axle-tree which answers to the wheels, and which passes through the centre of the blocks, is fixed the cylinder, or barrel *o, o*, which is closed at its end, *p, s*, and is likewise divided by two partitions *q, r*. This barrel is made of thin split deal, as are also the ends and partitions. *t, t*, is a thin board, or plate of tin or thin iron, fastened with hinges, that it may be opened to put the seeds into the three partitions *p, q, q, r, r, s*. In the middle of each of these partitions, the barrel is pierced with holes three or four inches asunder, and about a quarter of an inch in diameter. The barrel and the wheels are fixed on the iron axle-tree, that they all turn together.

To know whether the holes *u, u, u*, in the three partitions of the barrel are of a proper size and number to distribute the seed in the manner this is desired, let some, suppose half a bushel, be put into each partitions. The blocks *n, n*, being placed on each side, between the two standards, whose inner sides are rounded so as to fit the groove in the block, and the table S, S, being raised so that the wheels do not touch the ground, any one may easily see, by giving the wheels a turn or two round with the hand, whether the proper quantity of seed drops behind the share; and alter it accordingly.

The barrel being properly fitted, the beam is fastened to the fore-carriage of this drill. As it moves, the barrel turns with the hind wheels, and the seed drops out of the holes *u, u, u*, fig. 8, into the cavities *a, a, a*, fig. 7, and from thence into the hollow *c*, fig. 6, in the hind part of the share.

When the plow man comes to the end of the field, he lifts up the hind carriage, which is light, and carries it till the horses are turned for the next furrow.

M. Duhamel does not fix the diameter of the hind wheels, but leaves that to be determined by the length of the shares. His were so proportioned that where the shares touched the ground, the wheels did not touch it by two inches. He observes, that this drill answered extremely well, where the ground was ploughed into an even or level surface: but that the wheels were too small, when the middle of the ridges was raised high; because the shares were then on the higher part of the ridge, while the wheels were in the furrows.

In fig. 7, are two thin boards *x, x*, somewhat bending, which rise up to about half the height of the barrel. The use of these is to catch the seeds that may chance to drop from the oblique holes, and guide them into the cavities *a, a, a*.

It is well known, that when the fore-part of the share terminates in a point, it pierces the deeper into the earth, the farther back the beam is placed on the fore-carriage: but as the bottom of these shares is round, they pierce neither more nor less when the beam is placed more forward. It is therefore advisable to place the fore and hind

carriage as near as possible to each other, because the plough then goes easier, and the draught is lighter to the cattle.

The instrument is easily transported from place to place by means of two poles *y, z, z*, fig. 7. The ends *y*, are placed on the fore carriage, together with the beam, and from thence pass under the table, so as to raise the whole from the ground, on which the other ends *z, z*, rest. The cross bar *k, k*, secures those ends, and keeps them at a proper distance.

M. Duhamel took the first hint of his seed box from an invention of Mr. Grenville, a gentleman belonging to the king of France's stables. This was a hollow ball, fixed upon the axle-tree of two wheels, and pierced round the middle with a row of holes, through which the seed dropt as the wheels turned round. Upon a similar principle, another gentleman, instead of sowing under furrow in the common way, contrived a box to turn behind his plough; and that no more than the due quantity of seed should be dropped; the lower half of the box moved upon a belt of leather, in the middle of which was fixed a piece of brass, pierced with a hole suited to the size of the seed intended to be sown. By this means, the holes in the box could not drop any seed, but when they came opposite to the hole in the belt. A few grains were indeed sometimes bruised in their passage; but, upon the whole, there was a great saving of seed.

According to the above construction of M. Duhamel's drill, the shares must always pierce to the same depth, because the whole weight of the hind part of the drill rests continually upon them: consequently, it would be necessary to have shares of as many different lengths, as there are depths, at which each kind of seed should be sown.

We likewise apprehend, that when the shares have pierced to the depth intended, the weight of the drill may be made to rest on the wheels, by preventing the axle-tree from rising between the standards, beyond such a height as shall exactly regulate the depth to which the shares are to pierce. This may be effected, by bringing the standards *b, b*, fig. 7, nearer to each other; and placing between them, instead to the blocks *n, n*, fig. 8, two thick pieces of wood, made to slide up and down, with grooves, as in the blocks. These pieces of wood may be fixed between the standards, by means of two strong iron pins run through the standards into them: and to take off the friction of the axle-tree against these pieces of wood, may be made to turn on two friction wheels, placed in the lower part of them; or rather on four or six small iron rollers turning on their axis in a box inserted in each of these pieces, which may be raised or lowered, by means of a row of holes in the standards, through which the iron pins are put so as to give the axle-tree room to rise to the height that shall be thought necessary to make the shares pierce to the intended depth, before the weight of the drill shall rest upon the axle-tree.

That the axle tree, moving on such roller, will have less friction, or require less strength to make the wheels turn round, even when the weight of the whole instrument lies upon it, than it has in the blocks, with only the weight of the grain, is evident from the following fact. The gentleman who first thought of this invention, applied to it a roller of four tons weight, which is now drawn with ease by two ordinary horses, even across his ploughed grounds.

It appears from this easy motion of the roller, that there can be no danger of the axle-trees turning, though loaded with the weight of the whole instrument. Other considerable advantages will also arise from the drill's resting thus upon the wheels; for the labour of the ploughman will be greatly lessened, the instrument will move steadier and more uniformly, and the draught will be much easier for the horses.

Description of M. de Chateaucieux's DRILL-Plough, and of its manner of working. Written by himself.

"When I first set about constructing this drill-plough, my design was to make an instrument which should distribute the grains of corn one by one, at the distance of six inches from each other. I attained this precision; but soon perceived that it was not the only thing requisite, or even so necessary as I had imagined.

"I could, indeed, make my drill distribute some grains more than it did in its first state: but I plainly found that

the quantity of seed would not yet be sufficient to produce a proper number of plants; especially as it must not be expected that every seed will grow; 1. because, whatever care be taken in chusing the seeds, there will always be among them many which will not sprout at all; 2. because a great number of them will be destroyed by insects, either before they vegetate, or soon after they spring up; and 3. because the winter's cold will frequently destroy several of the young plants, and greatly weaken others. Experience taught me, that, to guard against the effect of these casualties, it was necessary to sow more seed than I did at first.

"To this end, and that I might be enabled to increase the quantity to whatever degree should be found most proper, I enlarged the cavities of my cylinder, so that I can now sow either more or less seed, with equal ease, by means which shall be explained in the description of this instrument.

"Each of these cavities, in the cylinder of my first drill plough, could contain but one grain of corn; but in the present, they are large enough to hold three or four, which, through they touch one another there, are so separated when they fall from thence, and in their passage through the pipes, that they drop at distances from each other in the furrow; for they are not all turned out of the cavities in the cylinder at the same time: besides which, I have observed, that the ground upon which they fall is always more or less uneven, and that this circumstance consequently contributes effectually to separate them.

"I confess that the description which I am going to give is very long, and that this, together with the sight of so many figures as are here represented, may, at first, make people think that my drill is a very complicated machine, and that this complication must render it very defective: but I beg of them not to give way to this prejudice, and to suspend their judgment till they have studied the instrument thoroughly; after which, I hope they will be sensible that all its mechanism is employed only to procure the movement of the axis, and the play of the valves. I even flatter myself that it will be deemed a simple instrument, by those who rightly consider how few of its parts are moved; a circumstance which prevents its being put out of order in working. The great quantities of land which were sowed in the autumn, with perfect success, ought to remove the diffidence of those who may still incline to doubt whether this drill will always and regularly perform equally well.

"It will perhaps be objected, that the expence of making this drill plough is too great, and that numbers of farmers, who have not much land, may not be able conveniently to purchase it.

"It is very true that if this instrument could be constructed for a small price, the benefits resulting from it would be the more extensive: but it must also be allowed that this objection does not hold good with respect to all farmers, or to gentlemen who keep ground in their own hands. These will soon be repaid the expence of such a drill, by the saving of seed; and as to the poorer sort who have, for example, but ten or twelve acres of arable land, the expence will be but trifling, if four or five neighbours, in that case, join to purchase such a drill, which will be more than sufficient to sow all their ground. Or, each parish may come to an agreement, that he who can afford to buy such a drill, may let it out for so much an acre; a method which would be advantageous to all; but particularly to those who, by using it, would sow their land with very little charge.

"But I think, and hope, that when the great advantage of using this instrument is known, no husbandman will be without it merely because of the price; as this consideration can never out-weight the benefits which will accrue from it in all respects, by lessening the expence of every article in the operation of sowing, and by the farther emoluments which will be reaped at harvest.

"I therefore, in constructing this instrument, paid less regard to the price which it might cost, than to the means of rendering it very solid, by a firm assemblage of all its parts; which was essential, in order to prevent the frequent accidents it would otherwise have been exposed to, in the hands of ignorant peasants, who have no idea of handling things gently, and are still less capable of repairing any mischief done to a very nice machine.

"At the same time I studied strength and solidity in the

the construction of this instrument, it was not less necessary to take particular care that it should execute well and regularly the purposes for which it is intended, both with respect to the manner of its distributing each grain, and to the movement of the axis, which is always in motion from the moment the horse stirs, so that the seed runs incessantly.

In describing this instrument, I have first given a general idea of its make and manner of working, that the reader may be thereby enabled the more easily to understand the subsequent minute description of all its parts, with their relation to, and connection with, each other. The method of using it will then follow.

General Idea of M. de Chateauxvieux's DRILL-PLOUGH, Plate X.

A (fig. 1.) is a wooden-box, or hopper, whose bottom is at the height of the line F G. This hopper has four feet, two of which are seen at *k* and *l*. These four feet, which may be called tenons, are fitted into four mortises in the table H L. The bottom F G of this hopper rests immediately upon the feed-box B, which is made of thin plates of brass, and is placed between the bottom of that upper box or hopper, its two sides which have the four feet, and the table H L. B is the front of this feed-box. The corn drops through a hole in the middle of the bottom of the hopper A, into the feed-box B. This feed-box B contains a brass cylinder, which traverses it, and is pierced by and fixed to an iron axis M P, at the two ends of which are firmly fastened two pulleys Q and P. The two pivots of the axis are supported by two standards, one of which is seen at M H, and a part of the foot of the other at L. These two standards are fixed to the two ends of the table by two keys, like those of a turner's lathe.

The table upon which all these pieces rest, is itself, at its two ends, supported by, and fastened to the two beams T V, R S. These two beams are fixed in parallel lines, by a traverse X Z. In the middle, U, of this traverse, is pinned the end of another piece of wood, which passes from thence under the table, in a parallel direction with the two beams, and upon which also this table is fastened by two screws.

This instrument has three exactly similar shares, D K, *e*. Two of these shares, K and D, are fastened to the two beams, at I and *p*, by a tenon and a peg, and the third is fastened in the same manner, towards U, to the piece which runs parallel to the beams. Each of these shares is covered at the bottom with a plate of iron, N, E, C, and the point of one of them, supposed to be in the earth, is seen at Y.

The harrow is composed of three pieces of wood *q* O, O W, W *n*, jointed together by mortises and tenons at O and W, and of two similar iron teeth W *z*, O R. These two teeth are fastened to the harrows by the screws W and O, and the harrow is fastened to the traverse X Z by two hinges near *q* and *n*. Upon the two beams are fastened by two screws, at *m* and *e*, two square springs *m i q* and *e Z n*, of which the two ends, *q* and *n*, press upon the harrow, to make its own teeth enter into the earth.

The fore-carriage is composed of two similar and parallel pieces, V *r*, S *s*, upon which is fastened the spring-tree bar *r s*, and the axle-tree *u t* of the two wheels. The drill (of which the manner of working will be explained hereafter) rests upon this fore-carriage, whenever there is occasion for its so doing, by means of a wooden bar *d s*, one of the ends of which, towards *a*, passes through two belts which are fastened to the table, and of which only one is seen here. The other end *s* of this bar, rests upon the middle of the axle-tree of the fore-carriage, between two pins driven into the upper part of that axle-tree. The fore-carriage is likewise fastened to the drill by hooks and rings, as at *v* and S.

At *t* and *u* are two pulleys, which are fastened to the spokes of the wheels by three or four screws. The pulleys Q and *u* are encircled by a thong of leather, of the same breadth as the grooves of the pulleys, and of which the two ends are buckled together, like a garter. The two other pulleys P and *t* are encircled in the same manner by another similar thong.

Manner in which the DRILL works, Plate X.

The seed being put into the hopper A (fig. 1.) the whole machine being drawn by the horse harnessed to

the spring-tree bar *r s*, and guided by the seedsmán, who holds the two handles; then the three shares, D K *e* C, open each of them a furrow, and at the same time the pulleys, *u t*, by their turning, turn by means of the thongs, the two other pulleys, Q P, and consequently likewise the cylinder, which is in the box B, and which, in turning, distributes the seeds equally into three pipes which come out at the bottom of the feed-box. This distribution of the seed is performed by a mechanism which cannot be represented here, but will be particularly explained hereafter. The ends of these pipes are seen here at *a* and *b*. These pipes *a* and *b* drop the seed into two other pipes *d* and *f*; the pipe *a* transmits its contents into the pipe *d*, which terminates behind the share D, at *b*, where it deposits the seeds in the furrow made by this share. In the same manner, the end of the pipe *b* of the box conveys the seed which passes through it into the pipe *f*, which terminates at *g*, behind the share K. And likewise in the same manner, the third pipe of the box, which cannot be seen in this figure, empties its contents into a third pipe, of which part is seen here at *v*, *y*, and which terminates behind the third share *e*, C. The two teeth of the harrow, passing afterward each of them between two of these furrows, cover the seeds which have dropped into the three furrows.

According as the screw B, in the fore-part of the box, is turned more or less from the right to the left, or from the left to the right, a greater or less quantity of seed drops into each furrow, by means which will be explained hereafter. But so long as this screw remains in the same situation, the quantity of the seed that is dropped, will be constantly the same.

To render the description of this first figure the more distinct and intelligible, some things are passed over here which will be spoken of hereafter, and among others, two traverses which fastened together the two pieces V *r*, S *s*, of the fore-carriage. Also the box B is here made larger than it should be, according to the description which will be given of it, in order that the pipes *a* and *b*, *d* and *f* might appear the more distinctly. For the same reason also the out-lets of the pipes *a* and *b* are not here represented as let into the mouths *d* and *f* of the two other pipes, as they should be in fact.

In the following descriptions, that part of a piece which immediately faces the horse, is always called the fore-part of the piece, excepting only the piece named the bin, and its valves, in speaking of which the contrary rule is observed. But, every where, the right or the left side of a piece, is to be understood as of the same side of the horse.

When a machine is to be made from drawings, those drawings, especially when small, cannot, by their scale, point out precisely the exact dimensions of every nice, and oftentimes very important piece, so as to enable a workman to construct it perfectly. To remedy this defect, all the measures of every piece, and their connection with each other, are here particularly specified in the following description, which is to be looked upon as a surer guide than the measures resulting from the engraved figures: and to render this still more certain, the weight of the nicest pieces is also given.

Description of the two Beams which support the Table and the Hopper, Plate X.

The two beams T V, R S, (fig. 1.) are represented as if seen from above at *a*, *b*, *d*, *e*, (fig. 2.) They are exactly similar. Each of them is three feet five inches and a half long, two inches and five-sixths wide (for example from *b* to *e*), and one inch five-sixths thick. All their sides are at right angles to each other.

These two beams are joined by a traverse *f b* (fig. 2.) and X Z (fig. 1.) This traverse is two inches and five-sixths wide, measuring it horizontally, one inch and three-twelfths thick, and one foot and a half long, exclusive of two tenons, one at each end, by which it is mortised into the two beams, which are parallel to each other. The upper surface of these beams, that of their traverse, are exactly even. The distance from *e* to *f* (fig. 2. Plate XI.) is one foot eleven inches and a quarter; and the same from *i* to *b*.

Underneath each beam, and at the distance of five inches from the extremity *a* (fig. 3.) an iron-pin, seven-twelfths, or two thirds of an inch in diameter, projects to the length of four inches and one-third. One of these pins is seen at Δ (fig. 1.) Its other end is driven fast into the middle

of the under surface of the beam, from which it projects perpendicularly. These two pins are to enter into two holes in the axle-tree of the hind-carriage, which will be spoken of hereafter.

Of the two Handles, Plate X.

Two handles, $k n$, $l m$ (fig. 2.) are fastened to the two beams, each of them by a tenon d , (fig. 3, Plate XI.) five-sixths of an inch thick, which passes through the beam, and is secured underneath it by a wooden pin or peg d , about half an inch in diameter. Each handle is likewise supported upon the beam by a wooden prop $p l$, which is seen at R and T (fig. 1.) Each of these props is three quarters of an inch in diameter, and is driven very tightly into the handle and the beam, at p and l (fig. 3, Plate XI.) so as to pass quite through them. The upper end c of these props is seen at V and X, in fig. 2. From the extremity k of the handle (fig. 2, and 3.) to the extremity a of the beam is one foot, and one-third of an inch, and the distance is the same from d to l , in fig. 2. The breadth and thickness of the lower end of the handles at $g k$ (fig. 2, Plate X. and 3, Plate XI.) is nearly the same as the breadth of the beams, upon which they rest: but they lessen by degrees from k to n , and are rounded off, in such manner that the diameter of their upper end n is but one inch and a third.

With respect to their position, they form, with the beams, an angle of 40 degrees, as at $c k a$ (fig. 3, Plate XI.) The handle is nearly straight from k , to about a third part of its length, and from thence it bends more and more downward to its end n , which is perpendicularly two feet higher than the upper surface $k m$ of the beam. This height is expressed by the pricked line $n m$. The space between the handles likewise increases with their length, so that, at their smallest ends, the distance from the outside of the one, to the outside n of the other (fig. 2, Plate X.) is one foot eight inches and a half, and each of them is equally distant from the middle line $o p$.

These two handles are fastened to each other by a traverse $q r$, which is represented in fig. 1, but is expressed here only by two pricked lines, in order to shew a piece which is under it, and which will soon be spoken of. This traverse is one inch and five-sixths broad, and two-thirds of an inch thick. Its ends, being tenons, are let into mortises in the beams, and fastened there by wooden pins, at q and r . One of these ends appears at q (fig. 3, Plate XI.) From the middle of the length of this traverse hangs an iron hook, as in fig. 1, Plate X. This hook is about a quarter of an inch thick, and five inches and a half long, from its extremity e (fig. 3, Plate XI.) to its other end, which is fastened to the traverse. The lower end of this hook is put through a small ring fastened to the harrow between the screws of the two teeth, and serves to hold up the harrow when the drill is placed upon its hind-carriage, in order to be removed, as will be said hereafter. The traverse is fixed in the handles at the distance of thirteen inches from their extremity k (fig. 2, Plate X. and 3, Plate XI.) The two handles, which the seedman holds in his hands by their ends $m n$, serve to direct the drill.

Of the Harrow, Plate X.

The harrow is composed of three pieces of wood $s t$, $y x$, $t x$, (fig. 2.) and of two teeth fastened to this last. The three pieces are represented at $q O$, $O W$, and $W n$, and the two teeth at $W z$ and $O R$, in fig. 1. The two pieces $s t$, $y x$, (fig. 2.) are each of them fastened to the traverse $s y$, by an iron hinge, in such manner, that the upper surface of the ends s and y of these two pieces is exactly level with the upper surface of the traverse $s y$. Their two other ends, t and x , are terminated by a tenon which is pinned into the ends of the traverse $t x$. The upper surface of these three pieces $s t$, $y x$, $t x$, is perfectly even.

The two pieces $s t$, $y x$, are each of them one foot eight inches long, from the end s , to the traverse at t . They are two inches and one-third broad, measuring over their upper surface, and one inch and two-thirds thick. The fore-end of these pieces towards the hinge, makes an angle of about sixty-five degrees, with the upper surface, as is represented in the profile (fig. 4.) where the lines $d a$, $a b$, express this angle. This slope is made in order that the harrow may the more easily press upon the ground, by moving on its hinges; and for the same reason,

all friction between the sides of the harrow and those of the beams is avoided, by leaving an interval of about one-sixth, or one quarter of an inch between them. The lines, or edges $t s$; $x y$, (fig. 2.) are parallel; and the distance between them is one foot and five-sixths of an inch. The traverse $t x$ is two inches and nineteen twenty-fourths wide, and one inch and two thirds thick.

In the middle of the breadth of the upper surface of this traverse, and cut perpendicularly to that surface, are two square holes, M and N, distant from each other seven inches and a half, from the center of one to the center to the other; and both equally distant from the middle line $o p$.

Of the Teeth of the Harrow, Plate X.

In these two holes M N in the traverse of the harrow are fastened, as will soon be seen, two iron teeth, perfectly alike, so that it will be sufficient to describe one of them. This tooth is shaped almost like the head of a lance, if we suppose its two sides to be bent towards each other, so as to form a kind of groove or channel. These two sides, or fins, are seen in perspective, sideways, in fig. 5; behind in fig. 6; from above, and from before, in fig. 7.

The shank $b d$ (fig. 5.) is five inches and an half long, from its rise at $a b$, to its end d ; and three quarters of an inch thick at $a b$, where it is made square. This thickness is increased a little at c , in order to form the shoulder represented at $a b$ (fig. 7.) The distance from $a b$ (fig. 5.) to this shoulder c , is three inches. The square thickness of the shank, from c to n , is half an inch; which is likewise the size of the holes M N (fig. 2.) The rest of the shank is round, and half an inch in diameter. Its upper end is a screw, fitted to receive a nut about half an inch thick, and a little more than an inch square. The point e does not vary from the direction of the shank, either to the right or the left, as appears by fig. 6: but the side $b c$ (fig. 5.) bends a little forward, so that the point e advances one inch and a quarter beyond the pricked perpendicular $n b f$. The upper and outer extremities c and f of the fins (fig. 7.) are two inches and one-twelfth distant from each other, and equally distant from the middle of the shank. The width of each fin, in this part, from s to f , or from s to c , is one inch and an half. From thence they lessen by degrees down to their point. The edges of these sides, or fins, are almost sharp, but their thickness and strength increase towards their back.

The two teeth of the harrow are placed exactly in the middle of two parallel lines supposed to be drawn from the point of the shares; by which means these teeth will enter into the ground at equal distances from the small furrows made by the shares, into which they will throw back the quantity of earth necessary to cover the seeds perfectly.

As to the position of these two teeth, they are fastened in the two holes M and N of the traverse $t x$ (fig. 2.) as is represented by the perspective view of them in fig. 8. The shank of each tooth is run through the hole in the traverse $x t$; its shoulder is trussed up close to the under surface of this traverse; and a nut, under which is placed a very thin plate of iron, fixes at the top. The back and point of these two pieces should face exactly the fore part of the drill.

Hinges of the Harrow, Plate X.

To return to the hinges s and y (fig. 2.) which are exactly alike, and which are seen at q and n in fig. 1. Their breadth is one inch and two-thirds, during their whole length, from v to f (fig. 2.) The joint s , of this hinge, is half an inch in diameter. The claw, from the joint s to f , is two inches and a quarter long, and is fastened to the traverse $f b$ by a thumb-screw represented in perspective in fig. 9, and which screws into a nut $a b$, which is fastened to the bottom of the traverse by two nails. This screw (fig. 9.) is one-third of an inch diameter. It is screwed down by means of a corresponding screw in the nut under the traverse, till its shoulder $c n$, which is two-thirds of an inch in diameter, presses upon the claw of the hinge: for which see also fig. 4. The length of the other claw of the hinge $s v$ (fig. 2.) from the joint s to its end v , is four inches and a half. The thickness of each claw towards the joint is a quarter of an inch, and from thence that thickness lessens by degrees to the end v . The claw $s v$ is fastened to the piece $s t$ by two flat-headed screws.

Spring of the Harrow, Plate X.

Upon this claw, and between these two screws, presses the end B of a spring A z (fig. 2.) which forms an angle at A, and is fastened to the beam a b, between D and z, by two flat-headed screws, of which the last D is two inches and an half distant from the end z of the spring. These two springs are seen at m i e Z n in fig. 1. The length of this spring from z to A (fig. 2.) is thirteen inches and an half, and from the angle A to B two inches and a quarter. Its breadth at z is one inch and an half; at N it is one inch and one-twelfth; and at B it is thirteen twenty-fourths of an inch. Its thickness at z is five twenty-fourths of an inch, and from thence that thickness diminishes to A, where it is but one-sixth of an inch. The part A B increases in thickness from A to B, where it has a head, which alone presses upon the claw of the hinge between the two flat-headed screws. This part of the spring, with its head, is represented plainly, in perspective, in fig. 10. When this spring is in its state of rest, the whole of its under surface from N to z (fig. 2.) lies exactly flat upon the upper surface of the beam. The end z of this spring is fifteen inches from the end b of the beam to b. These springs should be made of good well-hammered stuff, prepared like that which is used for the springs of coaches; by which means they will have a body, and not be subject to break or bend. If they appear to be too weak, they may be placed a little farther from the joint of the hinge; in which case they will the better press the teeth of the harrow down into the ground.

Connection of the Beams, with the Table and Shares, Plate X.

The thickness of a quarter of an inch is taken off from the upper surface of each of the two beams, from z (fig. 2.) immediately adjoining to the end of the spring, to Q, in the one, and from E to F in the other; being in length eight inches and two-thirds. In these lower spaces, is placed the table, which will soon be spoken of, and of which the extent is here indicated by the pricked lines. This table is seen at H and L, in fig. 1. It is fastened to the beams by four strong flat-headed screws, at z, I, G, and H (fig. 2.) and is seen in profile in fig. 3, Plate II. at i and r. This table rests likewise upon a piece K L (fig. 2.) of which the end K, being a tenon, is pinned into the middle of the length of the traverse f b; as is also seen at U (fig. 1.) This piece K L (fig. 2.) is two inches and five-sixths broad, measuring it horizontally, and one inch and five-sixths thick. Its length is such, that its end L reaches, at most, no farther than the edge Q F of the table. At the end of this piece appears a ring, which is fastened under it, and of which the description and use will be seen hereafter. The upper surface of this piece K L, from K to Y, is level with the upper surface of the two beams, and the traverse f b; but from Y to its end, a quarter of an inch is taken off from its thickness, in the same manner as from the opposite parts of the two beams, to fit it for the reception of the under surface of the table. A side view of this is given in fig. 11. where a b is the profile of this surface, which, from a to b, is level with the surface d a of the traverse, and from b, to its end c, is a quarter of an inch lower, that the table may rest upon it.

In the middle of the breadth of the upper surface of this piece K L (fig. 2.) and perpendicular to that surface, a mortise P is cut quite through it, to receive the tenon which is seen at U, fig. 1. This mortise is throughout two inches long, and one inch wide. Its end P (fig. 2.) is three inches and eleven-twelfths distant from the traverse f b. These two beams are pierced in the same manner by two similar mortises Q and R, of which the ends Q and R are one inch and eleven-twelfths distant from the side S T of the table. The tenons which pass through these two mortises are seen at I and p in fig. 1. These three mortises are to receive the tenons of three exactly similar shares, of which the following is the description. These three shares are seen at D, K, and c, in fig. 1.

Of the Shares, Plate XI.

The shares are cut out of a plank, and fig. 12. represents one of their two surfaces. The lines which limit this surface are perpendicular to each other, excepting i d; the line d c is six inches long; c f, nine inches; f g, two

inches and a quarter; g h, five inches and an half; l m, two inches; and h i, half an inch. This plank is every where an inch thick, except at the edge e d, where it forms an acute angle; as at b, fig. 13, which represents the bottom of the plank c d (fig. 12.) The part g h, in which is the hole k, is the tenon which enters into the mortises P, Q, R, (fig. 2.) before described. Fig. 14. represents the top of this plank, and of its tenon.

Fig. 15. is a perspective view of an iron share which is fixed under the plank, as in fig. 17. Its point (fig. 15.) extends from e b to f. Its sole, which extends from c h to a e, and the ears a b, c d, are all of one piece. Fig. 16. represents a geometrical plan of this share, in which d f, and g h are the places from whence the two ears arise.

The length of the point from e b to f (fig. 15.) and from a b to c (fig. 16.) is four inches. Its height towards b, or towards e (fig. 15.) is about one inch and a quarter, and from thence it lessens gradually to f, which is the point. Its breadth a b (fig. 16.) is the same as the thickness e o (fig. 13.) of the plank of the share, and it lessens gradually from thence to its point c (fig. 16.) A notch is made in the upper part of this point, between e and b (fig. 15.) or between a and b (fig. 16.) to receive the lower end of the angular side a b c (fig. 13.) of the plank.

The sole e a (fig. 15.) or a d (fig. 16.) is of the same length and breadth as at the bottom c m, or o n (fig. 13.) of the plank which it covers. It is about, but not more than two-thirds of an inch thick towards e b (fig. 15.) and half an inch thick at its end a c.

Towards this end are the two thin iron ears, which lie close to the two sides of the plank, to which they are fastened by a single nail, which passes through the plank, as at b, fig. 17.

This share is also fastened to the bottom of the plank by a flat-headed iron pin, g h, fig. 15; which goes through the share at n, and enters into the middle of the thickness of the plank. The head h of this pin is flat, and lies even with the bottom of the sole, in the manner indicated by the pricked lines at a, fig. 17. Towards the flat end c of this pin is a hole, through which, and through the plank, a smaller pin or nail is driven, and is denoted by being pricked in the same figure.

The point of the share, and the bottom of the sole, which rubs upon the ground, should be of steel. The different thicknesses given to the sole, shew that its point inclines a little downward, by which means it enters into the earth very easily.

Fig. 18 represents a perspective view of a thin plate of iron, which is to cover the plank of the share, as in fig. 20, to preserve it from the friction of the ground, which would otherwise soon wear it out. The thickness of this plate, which should be equal every where, is at most one-twelfth of an inch. It is bent at a b, fig. 18, in such manner that this bending fits close to the sharpened edge c d, fig. 20, of the plank; the angle b, fig. 18, being fitted to the notch c (fig. 20) in the iron part of the share, and the lower edges b c, a d, of this plate (fig. 18) joining on both sides to the upper edges of the sole of the share, as in fig. 20. The breadth of this plate from a to b (fig. 20.) is about four inches, and each half of its length, from c to a, or from d to b, is about seven inches and a half. Fig. 19 is the plan, or bottom of this plate.

As this plate covers the ears of the share, and at the same time its own angle c (fig. 20.) is covered by the point of the share, these two pieces must be put on together. This plate is nailed to the two opposite sides of the plank.

The two ends of this plate extend beyond the hindmost part of the plank of the share, in the proportion of b h, fig. 20: and in this space, between these two ends, is the opening of the pipe through which the seed drops into the furrow, as was said before.

The tenon / g (fig. 12.) of the share now described, (and there are three such) enters into one of the three mortises, P, Q, R (fig. 2.) through the bottom of which it is passed, and is fixed above by a wedge driven into the hole k (fig. 12.) These shares are situated in such manner, that their point faces directly to the fore part of the drill. One of them is represented as fixed towards the end b of one of the beams, in fig. 3, which exhibits the profile of that beam.

Of the Piece which is placed under the Middle of the Table, and which bears the middle Share, Plate XI.

The piece K L (fig. 2. Plate X.) which has been already spoken of, is represented with its bottom upward, and in perspective, at *a b*, fig. 21, Plate XI. with the share A, and its tenon B, and with the table, which are also inverted in the same manner. Fig. 22 is a geometrical representation of the under side of the same piece, and of part of the table, excepting the share which is omitted here, and of which only the bottom of the mortise is seen at B.

At the end L of this piece (fig. 22.) is fastened the rein or bridle before mentioned. This bridle is shaped nearly like a horse-shoe; the breadth of each of its branches is three-fourths or five-sixths of an inch; its total breadth is the same as that of the piece to which it is fastened; its total length is three inches and a half, and its thickness every where is about one-sixth of an inch. The whole thickness of the two branches of this bridle is let into the piece of wood to which it is fastened; so that it forms an even surface. This bridle is fastened to the piece by two flat-headed screws, which lie even with the branches of the bridle, through and into which they are screwed. It is placed in such a manner, that the outside of its circular part L is one inch and a quarter distant from the edge *e f* of the table. It is used only when the drill is put upon its hind carriage.

a and *b* are the heads of two large flat-headed screws, which pass through the piece K L, and fix it to the table. From the center of the head *b*, to the edge of *c d* of the table, is one inch and two-thirds. From the center of the head *a*, to the edge *e f* of the table, is one inch and one-third. These two screws are placed in the middle of the branch of this piece L K. Their diameter is five-twelfths of an inch, and that of their head is an inch and a twelfth. These heads are flat, and screw in a level with the wood.

Of the two Bridles which receive the End of the Bar which supports the Drill upon its Hind-carriage, Plate XI.

Underneath this piece, K L, are likewise fastened two bridles very like each other. They are represented in perspective by the single figure 23; but both of them may be seen in their proper places, at *g h* and *e f*, fig. 21. Their place in fig. 22 is marked only by pricked lines, in order to let the pieces under them be seen. These two bridles are made of a flat piece of iron, one inch and a sixth wide from *a* to *b*, or from *c* to *d* (fig. 23.) and a very little more than one-sixth of an inch thick. They are bent square at *c d* and *f g*, and are pierced with two holes, *b* and *e*, one-fourth of an inch in diameter, of which the centers are three-fourths of an inch from the ends of the iron. Thus far these two bridles are like each other. What they differ in, is as follows: that which is placed at *g h* (fig. 21.) is three inches and one-sixth high, from its bottom *a*, to the upper surface of its top *c*, or from *e f*, fig. 23; and this height in the belt which is placed at *e f* (fig. 21.) is three inches and five twelfths: that which has placed at *g h*, is two inches and five-sixths long, from its outside at *c d*, to its outside at *g f*, (fig. 23.) and this part of the bridle placed at *e f*, is three inches and one third.

Both these bridles placed at *g h* and *e f* (fig. 21.) go over the piece of wood *a b*, to which their ends are fastened by flat headed screws, which pass through the holes *b* and *e* (fig. 23.) beforementioned. These ends rest immediately upon the table. As the distance between the ends of the bridle *e f* is exactly equal to the breadth of the piece to which they are fastened, they are applied to the two lateral surfaces of that piece, without being let into it: but as the bridle *g h* is not quite so long, the ends of this are let into those surfaces, as is seen in fig. 21. and in the picked plan of these two bridles, *b i*, *k n*, fig. 22. The ends of these bridles stand perpendicular to the table. The bridle *g h*, fig. 21, is one inch and fifteen twenty-fourths from the edge *t s* of the table; and the bridle *e f* is five inches and eleven twelfth distant from the same edge *t s*.

The use of these two bridles is to receive the end of the bar hereafter described, which serves to support the drill upon its fore-carriage, when the hind-carriage is joined to it: and to prevent this end of the bar from slipping out of these bridles, a moveable iron pin is put through it. This pin is suspended by a piece of pack-thread. It passes through

the bridle L (fig. 2. Plate X. and 22. Plate XI.) and *b* (fig. 21.) before described.

Of the upper Surface of the Table, Plate XI.

Fig. 24. represents a geometrical plan of the upper surface of the table, one end of which is omitted, as superfluous in this figure, because both its ends are alike. The pricked line *l b* is traced here only to mark the middle of the table, and determine some measures. The fore-ends of the beams appear here at *f* and *g*, with their mortises A and B, into which their shares are fastened. C, D, E, F, are the four large flat-headed screws which fasten the table to the beams. The diameter of these screws towards their head is five twelfths of an inch, that of their head is one inch and a twelfth, and their length is three inches and seven twelfths. They enter into the middle of the breadth of the beams, and the centers of the holes in the tables through which they pass, are eleven twelfths of an inch distant from the nearest edges of the table. The whole breadth of the table, at C D, or E F, is eight inches and two thirds. The two corners G and H are thirteen inches distant from the middle line *l b*, and the end K is one foot three inches and three fourths distant from the same line *l b*. The thickness of this table is every where one inch and two thirds.

At each end of the table is a notch K L P, of which the inner surfaces are perpendicular to each other. These notches are at H and L in fig. 1, Plate X. Each of them is three inches and three quarters, from K to L, fig. 24, and one inch seven twelfths wide from L to P. They are situated in the middle of the breadth of the table. Their use is to receive the lower end of two standards hereafter described (fig. 34.) of which one is seen at M H, fig. 1, and the base of the other towards L.

This table has two holes, M and N (fig. 24.) of which the upper openings are exactly equal, and alike situated, each of them forms a right angled parallelogram *a b i n*. The side *b i* is parallel to the edge D F of the table, from which it is one inch and an half distant, and its length is three inches and a quarter.

The upper edge of the end *a n* is eleven twelfths of an inch distant from the middle line *l b*, and its length is one inch and eleven twelfths. The inner and parallel sides *a b*, *n i*, of these holes are perpendicular to the upper surface of the table; but their ends *a n*, *b i*, are sloped, in such manner, that each of them forms an angle of fifty or fifty-five degrees towards the line *l b*. This is expressed in the profile of these two holes (fig. 25. by the angles *b a d*, *b e c*, and *g o f*, *g n h*, each of which has that measure. Q, R, S, T, are four mortises, of equal size and depth, cut perpendicularly to the upper surface of the table. Each of them is nineteen twenty fourths of an inch long in the same direction as the length of the table, two thirds of an inch wide, and about one inch deep. They are intended to receive the four feet of the hopper, which will be described hereafter. Two of these feet are seen in their mortises at *k* and *l*, fig. 1, Plate X. The centre of each of these mortises is six inches and five twelfths distant from the line *l b* (fig. 24.) and an inch and three quarters from the edges C E, D F, of the table.

Of the Bridles which receive the End of the Bar which supports the Drill upon its fore-carriage, Plate XI

From *k* to F, fig. 24. is a bridle which is seen in front in fig. 26. It is made of iron, one inch or one inch and a twelfth broad, and one sixth of an inch thick. It is bent in a semi-circle at *a c b*, and lies flat on the table at its end *a* and *b*, which are fastened to it by two flat-headed screws *a* and *b*, fig. 26. and *k m*, fig. 24. This bridle is perpendicular to the upper surface of the table. The highest part of the upper side of its arch *c* fig. 26, is two inches above the table; and its width, from outside to outside, from *c* to *i*, is two inches and a half. The length of each straight part, or claw, which is fastened to the table, is one inch and a quarter. The centers of the screws *k* and *m* (fig. 24.) are each one inch and three quarters from the middle line *l b*, and four inches from the edge D F of the table.

d r q (fig. 26.) is the upright of another bridle, of which the top, or upper surface, is seen at *x d p q*, fig. 24. (the front and side in the perspective figure 27, and the back and sides in the perspective figure 28. The hinder surface of the two claws, represented at *a* and *c* (fig. 28.)

28.) is screwed on to the fore-surface of the table, as at *f g* and *b k*, fig. 26, by two flat-headed screws, each of which is one inch and seven twelfths long, and near a quarter of an inch in diameter towards its head, which is half an inch in diameter. The middle of this bridle answers to the middle of the length of the table. The under surface of the bridle, and of its wings, answers to the plane of the fore-surface of the table, to which it is fastened. The length of each wing is about two inches and a half; their breadth is five sixths, and their thickness a quarter of an inch. The length and thickness of its arched part are equal to those of the wings. The bending of that part is such as is represented at *g d r q b*, fig. 26. The distance *g b* between the two wings is one inch and eleven twelfths. The greatest width of the bridle, from outside to outside, as at *d q*, is two inches and three fourths; and lastly, the upper surface of its highest part *r*, is one inch and two thirds above the upper surface of the table.

The use of these two bridles is to receive the end of the bar, which will be described hereafter. This bar is seen at *x d*, fig. 1, Plate X. where one of the rings appears towards *d*. A wooden wedge *o t* (fig. 24, Plate XI.) is slipped, if there be occasion for it, between this bar and the table, to which last it is fastened by a single flat-headed screw *t*, around which it turns, as around a center. The shape and extent of this wedge is such as is here represented according to the scale. Its thickness, throughout, is seven twelfths of an inch, excepting only at the part *r o e*, where its upper surface inclines from *r*, to *o e*, in such manner, that the edge *o e* is almost sharp, that it may slide, like a wedge, under the end of the abovementioned bar, which passes through the two bridles or belts. The length of this piece is five inches and one twelfth, from the center *t*, to its end *a e*. This center *t* is six inches and one sixth from the edge *D F* of the table, and four inches and a quarter distant from the middle line *l b*. We shall hereafter see, that the bar which enters into the two belts now described, ought not to fill entirely the belt *a b c*, fig. 26, but should leave room to introduce under it the wedge just spoken of, which is not to be inserted but when it is intended to make the other end of the bar press hard upon the axle-tree of the fore-carriage, which should never be done at the time of sowing, unless the husbandman would scarcely bury the seed.

Of the two Pipes of the Shares of the Beams, Plate XI.

Through the two holes *M* and *N* of the table (fig. 24.) pass two brass pipes, which descend to, and open at, the back of the sheers fastened in the mortises *A* and *B* of the two beams. These pipes are seen at *d* and *f* in fig. 1, from whence they pass through the two holes in the table, and terminate behind the two shares *D* and *K*, as is represented in perspective in fig. 29. These two pipes *f p a i k*, and *o r n l*, (fig. 29.) are perfectly alike. They are almost square during the whole length; wider towards the end *f d*, than towards the end *k*; and they are made of plates of brass, somewhat less than a twelfth of an inch thick, well soldered together. Their opening at *f d* forms a parallelogram, which is an inch and one sixth wide from *b* to *f*, and an inch and three quarters long from *b* to *d*. The plane or perpendicular projection of these openings in the table, is indicated in fig. 24, by the pricked lines between the letters *M* and *N*, where it is to be observed, that they are both equally distant from the middle line *l b*, and an inch and a half from the edge *D F* of the table. All the rims of these openings, *f, b, d, b, o*, (fig. 29.) are nearly parallel to the upper surface of the table, above which they rise two inches and two thirds. As these two pipes are alike, and situated in the same manner, one on the right, and the other on the left hand side of the drill, it will be sufficient to apply to one of them, what remains to be said of both. This pipe runs in a straight, but oblique line, from its opening *f d* to *i*, directly behind and under the share, from whence its direction becomes perpendicular to its other opening *k*, which is at the height of three inches and a quarter from the bottom *g* of the share. From its bending at *i* to the opening *k*, is three inches. This opening *k* is a square, of which the sides are two thirds, or three quarters of an inch long.

This pipe is held to the side *p* of the hole, by a piece of iron which is under the table; and it is also fastened near

the bending *i*, by another piece of iron fixed under the beam. These fastenings are seen in fig. 30, which represents, in perspective, the bottom *C D* of the table *E F* of the beam on the right-hand side of the drill, and the share *G* which is fastened to it. *q l* is the upper opening of the pipe, which runs from thence close to the side *a b* of the hole of the table, where it is fastened by a plate of iron, *n x*, about one eighth of an inch thick. In this plate is a notch which fits close to three sides of this pipe. This plate is fastened to the under surface of the table, by two flat-headed screws, *x* and *n*. The pipe continues in the same direction from its upper opening *q l*, to its bending at *e*, behind the share; but from thence to *f*, it follows the direction of the back of this share. It is fastened towards this bending by an iron square, *k i b g*, the thickness of which is about one eighth of an inch. This square is fastened under the beam by two flat-headed screws, *k* and *i*, and to the pipe by two other screws, *g* and *b*, the ends of which screw into a piece of iron, which is soldered to the pipe, and which is seen between the square and the pipe, from *f* to *c*. The beam *A B* has a shallow notch at *d*, to make room for the passage of the pipe.

Of the Pipe of the middle Share, Plate XI.

The two pipes which terminate behind the two shares fastened near the ends of the beam at *Q* and *R* (fig. 2, Plate X.) have now been described. A third pipe, of nearly the same form, terminates behind the third share, which is fastened at *P*, in the piece *K L*. This is the pipe which passes between *U* and *y*, in order to its terminating behind the share *e C*.

This piece *K L* is represented in perspective at *A B*, fig. 31, Plate XI. which shews its right side, with its share *C*, and the portion of the middle of the table, where are the two holes *D, E*, through which pass the two pipes beforementioned.

This third pipe is made like the two others, of plates of brass, of the same thickness and the same shape. Its opening, *b l* forms a parallelogram of nearly the same size as the similar openings of the two other pipes. The plane of this opening, or its perpendicular projection, upon the table, is indicated by pricked lines near *o c e*, fig. 24, where it is to be observed, that the middle of this parallelogram is in the middle line *l b* of the table, and that its side *c e* is five inches and five twelfths distant from the edge *D F* of the table. The rims of this opening *b l* (fig. 31.) are raised about two inches above the upper surface of the table. From thence this pipe descends in a straight, but oblique line, towards the share which is behind the table; and at the same time bears to the right to *d* and *c*, where it bends, in order to take the direction of the lateral surface of the piece *A B*, against which it rests. From thence it continues in this direction to *r*, where it bends again, to *p*, immediately behind the share; and there it is bent again, so as to descend perpendicularly behind this share, down to *k*, which is within three inches and a quarter of the bottom of the share *G*.
